Meters are usually so arranged as to swing freely about the long vertical pole to which they are clamped, and are provided each with a vane or tail similar to that of a windmill, for keeping the wheel in the proper position as regards the current. The wheels are generally made like those of a windmill; *i. e.*, with blades set at such an angle as to present a sloping surface to the current; and

*See Van Nostrand's Magazine, March, 1878, and August, 1886.

with the axis of the wheel parallel to the direction of flow. The axis runs in agate bearings. When desired, the rim of the wheel is furnished with an air-chamber, which just counterbalances the weight of the wheel, and thus removes journal friction due to it. Meters provided with electrical registering apparatus sometimes have the gearing and indices, etc., enclosed in a glass case, to prevent them from becoming clogged by weeds, sediment, etc.

A wheel meter is rated by moving it at a known velocity through still water, and noting the effect produced. In this way a coefficient is obtained for each meter, which, when multiplied by the number of revolutions recorded in any given case, gives the velocity for that case.

REM. 1. **Care must be taken that the bottom vel is not so great as to wear away the soil.** If there is any such danger artificial means must be applied to protect the channel-way; or it may be advisable to reduce the rate of fall, and increase the cross section of the channel; so as to secure the same disch, but with less vel. A liberal increase should also be made in the dimensions of such channels, to compensate for obstructions to the flow, arising from the growth of **aquatic plants,** or deposits of mud from rain-washes, etc; or even from very strong winds blowing against the current.

REM. 2. **Water running in a channel with a horizontal bed, or bottom, cannot have a uniform vel, or depth, throughout its course;** because the action of gravity due to the inclined plane of a sloping bottom, is wanting in this case; and the water can flow only by forming its *surface* into an inclined plane; which evidently involves a diminution of depth at every successive dist from the reservoir.

For theory of flow in long pipes and channels, mean velocity, distribution of velocity in cross section, Chezy formula, friction factor, exponential formulas, see pp 527, etc.

For Kutter's formula. see pp 523, 564, etc.

Bazin's Formula for Flow in Channels. Annales des Ponts et Chaussées, 1897, 4e trimestre, p 40.

In the Chezy formula, $v = c\sqrt{rs}$ where; (see p 528)

v = mean velocity;

$$r = \text{mean radius} = \frac{\text{cross section area}}{\text{wet perimeter}};$$

$$s = \text{slope} = \frac{\text{friction head}}{\text{length}}.$$

M. Bazin considers c independent of the slope, and gives:

For English measure.	**For metric measure,**
$c = \dfrac{87}{0.552 + \dfrac{\gamma}{\sqrt{r}}}$	$c = \dfrac{87}{1 + \dfrac{\gamma}{\sqrt{r}}}$

where γ has the following values;—

Very smooth surfaces, cement, planed wood, etc.,	$\gamma = 0.06$
Smooth surfaces, boards, brick, cut stone, etc.,	$\gamma = 0.16$
Ashlar Masonry,	$\gamma = 0.46$
Earth, very smooth, or paved with dry stone,	$\gamma = 0.85$
Earth, in ordinary condition,	$\gamma = 1.30$
Earth, very rough,	$\gamma = 1.75$

"In measuring the slope of a large river, the ordinary errors of the most careful leveling are a large proportion of the whole fall: the variation of level in the cross section of the surface is often as great as the slope for ten miles or more; the exact point where the level should be taken is often uncertain: the rise and fall of the water makes it extremely difficult to decide when the levels should be taken at the upper and lower points; waves of translation may affect the inclination to a great and uncertain degree, and may even make the surface slope the reverse way." Genl. T. G. Ellis, Trans Am Soc Civ Engrs., Aug 1877.

41

Kutter's Formula.

See also p 523. **For theory of flow** in long pipes and channels, see p 527.

Ganguillet and Kutter sought to establish a formula for the value of c in the Chezy formula:

$$v = c\sqrt{r\,s};$$

where v = mean velocity; r = mean radius $= \dfrac{\text{area}}{\text{wet perimeter}}$

s = slope $= \dfrac{\text{friction head}}{\text{length}}$.

The earlier hydraulicians gave (each according to the results of his investigations) *fixed* **values for the coeff c,** (generally about 95 to 100 for channels in earth or gravel, as in our early editions), making it, in other words, a *constant*, and independent of the shape, size, slope and roughness of the channel. But more recent investigators have shown that the coefficient c is affected by differences in any of these particulars.

According to the formula of Ganguillet and Kutter (generally called, for convenience, "**Kutter's formula**"*) the value of c is:

For English measure. **For metric measure.**

$$\mathbf{c} = \frac{41.6 + \dfrac{.00281}{\text{slope}} + \dfrac{1.811}{n}}{1 + \dfrac{\left(41.6 + \dfrac{.00281}{\text{slope}}\right)\times n}{\sqrt{\text{mean rad in } \textit{feet}}}} = \frac{23 + \dfrac{.00155}{\text{slope}} + \dfrac{1}{n}}{1 + \dfrac{\left(23 + \dfrac{.00155}{\text{slope}}\right)\times n}{\sqrt{\text{mean rad in } \textit{metres}}}}$$

Tables giving values of c for diff grades, mean radii and degrees of roughness, and for English and metric measures, are given on pp 566, etc.

Here **n** is a "**coefficient of roughness**" of sides of channel as given below. These values of n were obtained from experience, by averaging a large number of experiments made under very different circumstances. They therefore embrace all the disturbing effects arising from obstructions existing upon the bottom and sides of the channel in the cases experimented upon. In small artificial channels of uniform cross section and slope, these obstructions may be said to consist entirely of the comparatively minute roughnesses of the *material* of which the bed of the channel consists. But in rivers and earth canals, even where the *general* direction, slope and cross section are tolerably uniform, (as they were in the cases upon which our list is based), there are still many considerable irregularities in the sides and bottom; and these exert a much greater retarding effect upon the mean vel than the mere *roughness* of the material of the banks. We therefore find larger values given for n in such cases than for small regular artificial channels, although the material of the sides etc was in many cases smooth mud; and we must not apply to such comparatively irregular channels the small values of n obtained by experiments with small and carefully made straight flumes of uniform section and slope, even if we suppose the bottom and sides of the former to be made as smooth as those of the latter.

No general formula is applicable to cases of **decided bends** in the course of a natural stream, or of **marked irregularities in the cross section.** Such cases would require still higher coefficients n than those here given for rivers and canals; but they would have to be ascertained by experiment for each case, and would be useless for other cases. For such streams we must therefore depend upon actual measurements of the velocity, either direct or by means of the disch.

---

* See "Flow of Water," translated from Ganguillet and Kutter, by Rudolph Hering and John C. Trautwine, Jr., New York, John Wiley & Sons, 1889. $4.00.

There is much room for the exercise of judgment in the **selection of the proper coefficient n** for any given case, even where the condition of the channel is well known. It may frequently be necessary to use values of n intermediate between those given; for careless brickwork may be rougher than well finished rubble; side slopes in "very firm gravel" may have very diff degrees of roughness; etc etc. The engineer should make lists of values of n from his own experience, fully noting the peculiarities of each case, and calculating n from the tables.

A given diff in the deg n of roughness exerts a much greater effect upon the coefficient c, and thus upon the velocity, in small channels than in larger ones. It is therefore especially necessary in small channels that care be exercised in finding (by experiment if necessary) the proper value of n; and, where a large disch is desired, the sides of small channels should be made particularly smooth.

Table of n, or coefficient of roughness.

In any given case the value of **n is the same whether the mean radius is given in English, metric or any other measure.**

Artificial channels of uniform cross section.

Sides and bottom of channel lined with	n =
well planed timber	.009
neat cement (applies also to glazed pipes and very smooth iron pipes).	.010
plaster of 1 measure of sand to 3 of cement; (or smooth iron pipes).	.011
unplaned timber (applies also to ordinary iron pipes)	.012
ashlar or brickwork	.013
rubble	.017

Channels subject to irregularity of cross section.

Canals in very firm gravel	.020
Canals and rivers of tolerably uniform cross section, slope and direction, in moderately good order and regimen, and free from stones and weeds	.025
having stones and weeds occasionally	.030
in bad order and regimen, overgrown with vegetation, and strewn with stones and detritus	.035

Art. 22. The following tables give values of the coefficient c as obtained by Kutter's formula for diff slopes (S) mean radii (R) and degrees of roughness (n).*

Caution. Different values of c must be used with English and with metric measures. We give tables for both measures.

1st. Having the slope S, the mean rad R and the deg n of roughness; **to find the coeff c.** Turn to the division of the table corresponding to the given slope S. In the first column find the given mean rad, R. In the same line with this R, and under the given n, is the proper value of c.*

2d. Having the slope S, the mean rad R and either c or the actual or reqd vel v; **to find the actual, or the greatest permissible, deg n of roughness** of channel. If the vel is given, and not c, first find

$$c = \frac{\text{velocity}}{\sqrt{\text{slope} \times \text{mean radius}}}.$$

Turn to the division of the table corresponding to the given S, and in the first col find the given R. In the same line find the value given, or just obtained, for c; over which will be found the reqd n.*

3d. Having the slope S, the deg n of roughness, and the actual or required vel v; **to find the actual or necessary mean rad, R.** Assume a mean rad; and from the division of the table corresponding to the given S take out the value of c corresponding to the given n and the assumed R. Then say

$$v' = c \text{ so found} \times \sqrt{\text{assumed mean radius} \times \text{slope}}$$

---

* It is often necessary to interpolate values of S, R, n and c intermediate of those in the tables; this may be done mentally by simple proportion.

If this v' is the same as the given vel, or near enough to it, take the assumed R as the proper one. Otherwise, repeat the whole process, assuming a new R, *greater* than the former one if v' is *less* than the given vel, and *vice versa*.*

4th. Having the dimensions of the wetted portion (*abco* Fig C, p 528,) of the channel, the deg *n* of roughness, and the actual or reqd vel; **to find the actual or necessary slope,** S:

$$\text{Find the mean rad, R} = \frac{\text{area of wet cross section}}{\text{length, } abco, \text{ of wet perimeter}}$$

Assume one of the slopes of the tables to be the proper one. From the corresponding division of the table take out the value of c corresponding to the given R and n.

If R is 3.28 feet, or 1 metre, the value of c thus found is the proper one (because then c, for any given n, remains the same for all slopes); and the slope, S, may be found at once, thus:

$$\text{Slope, S} = \left(\frac{\text{given velocity}}{c \times \sqrt{\text{mean radius}}}\right)^2$$

But if R is greater or less than 3.28 feet, or 1 metre, say

$$v' = c \text{ thus found} \times \sqrt{\text{mean radius} \times \text{assumed slope}}$$

If this v' is near enough to the given vel, take the assumed S as the proper one. Otherwise, assume a new S, *greater* than the former one if v' is *less* than the given vel, and *vice versa*; and repeat the whole process.*

* It is often necessary to interpolate values of S, R, n and c intermediate of those in the tables. This may be done mentally by simple proportion.

Tables of coefficient c,

for mean radii *in feet*, and for mean radii *in meters*.

Table 1: for mean radii in FEET.

(For table with mean radii in *meters*, see pp 569, 570.)

For slopes steeper than .01 per unit of length, = 1 in 100 = 52.8 feet per mile, *c* remains practically the same as at that slope. But the *velocity* (being = $c \times \sqrt{\text{mean radius} \times \textit{slope}}$) of course continues to increase as the slope becomes steeper.

Table above is for mean radii in **FEET.**

For mean radii in **METERS**, see table, **pp 569-570.**

Table 2, of coefficient c, for mean radii in METERS.

For slopes steeper than .01 per unit of length, = 1 in 100, the *coefficient c* remains practically the same as at that slope. The *velocity*, however, being $= c \times \sqrt{\text{mean radius} \times \textit{slope}}$, continues to increase as the slope becomes steeper.

To construct a diagram, fig 30 A, from which the **values given by Kutter's formula** may be taken by inspection.

Draw *zz* hor, and say from 2 to 4 ft long; and *oy* vert at any point *o* within say the middle third of *zz*. On *oy* lay off, as shown on the left, the values of *c* for which the diagram will probably be used. If a scale of .05 inch, or .082 metre, per unit of *c* be used, and be made to include *c* = 250 for English measure, or 150 for metric measure, *oy* will be about 1 ft long. For the sake of clearness we show only the larger divisions in this and in what follows.

On *oz* lay off, as shown on its upper side, the *square roots* of all the values of the mean rad R for which the diagram is to be used. One inch per ft, or .06 metre per metre, of sq rt, is a convenient scale. *Mark* the dividing points with the respective values of the *mean radii themselves*

Having decided upon the *flattest* slope to be embraced in the diagram, say

$$w = 41.6 + \frac{.0028}{\text{flattest slope per unit of length}} \quad \text{for English measure.}$$

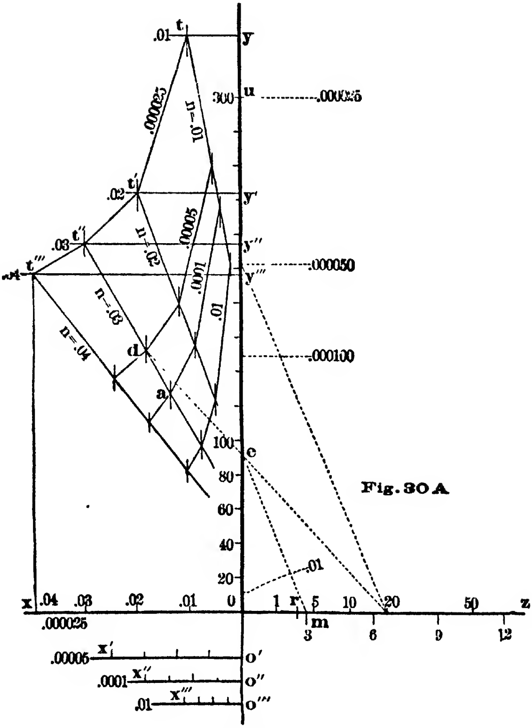

Fig. 30 A

$$w = 23 + \frac{.00155}{\text{flattest slope per unit of length}} \text{ for metric measure.}$$

For each value of n to be embraced in the diagram, say

$$y - w = \frac{1.811}{n} \text{ (English) or } y - w = \frac{1}{n} \text{ (metric).}$$

To each value of $y - w$, add w, thus obtaining values of y. We take .000025 per unit of length as the flattest slope, and .01, .02, .03 and .04 for n. Hence (using English measure)

$$w = 41.6 + \frac{.0028}{.000025} = 41.6 + 112 = 153.6.$$

$$y - w = \frac{1.811}{.01}, \frac{1.811}{.02}, \frac{1.811}{.03}, \frac{1.811}{.04}; = 181.1,\ 90.5,\ 60.4,\ 45.3 \text{ respectively,}$$

and $y = 181.1 + 153.6$, $90.5 + 153.6$, $60.4 + 153.6$ and $45.3 + 153.6$, or 334.7, 244.1, 214.0 and 198.9 respectively. Lay off these values of y on oy in pencil, as at y, y', y'', and y''', using the scale already laid off for c on oy.

From each point, y, y' etc, draw a hor pencil line yt, $y't'$ etc, and mark on it, in pencil, the value of n used in determining its height oy etc.

Next say $x = w \times$ *greatest* value of n. Make $ox = x$ by the scale of *sq rts* of R on oz. In our case $ox = 153.6 \times .04 = 6.144$ by the scale of *sq rts* of R, or $- - 6.144^2 = 37.75$ by the scale of R.

Divide ox into as many equal spaces (4 in our case) as .01 is contained in greatest n. Mark the dividing points with the values of n, as in our Fig.

From each dividing mark on ox erect a perpendicular, (xt''' etc) in pencil, to cut that hor line ($y'''t'''$ etc) which corresponds to the same value of n. The intersections are points in a hyperbola. Join them by straight lines $t'''t''$, $t''t'$, $t't$ etc.

From r in oz (corresponding to a mean rad of 3.28 ft, or 1 metre) draw radial lines, rt, rt', rt'' etc. Mark them "$n = .01$", "$n = .02$" etc, the same as their corresponding lines yt, $y't'$ etc.

For each slope (S) to be used in the diagram (except the flattest, for which this has already been done) say

$$x',\ x'' \text{ etc} = \left(41.6 + \frac{.0028}{\text{slope}}\right) \times \textit{greatest } n, \quad \text{for English measure.}$$

$$x',\ x'' \text{ etc} = \left(23 + \frac{.00155}{\text{slope}}\right) \times \textit{greatest } n, \quad \text{for metric measure.}$$

Thus, our slopes are = .000025, .00005, .0001 and .01 per unit of length. Hence,

$$x' = \left(41.6 + \frac{.0028}{.00005}\right) \times .04 = 3.904\,,\quad x'' = \left(41.6 + \frac{.0028}{.0001}\right) \times .04 = 2.784\,;$$

$$x''' = \left(41.6 + \frac{.0028}{.01}\right) \times .04 = 1.675.$$

Lay off each value of x', x'' etc from oy on a separate hor pencil line $o'x'$ etc, using the scale of sq rts of R as on oz.

Mark each line $o'x'$ etc in pencil with the slope used in fixing its length.

Divide each dist $o'x'$ etc into the same number of equal parts as ox. From the dividing points (which, like those of ox, represent the values of n) erect perps to cut the radial lines rt''', rt'' etc, each perp cutting that radial line which corresponds to the value of n represented by the point at the foot of the perp. The intersections corresponding to each line $o'x'$ etc form a hyperbolic curve. Mark each curve with the slope of its corresponding line, ox, $o'x'$ etc.

The drawing is now in the shape proposed by Mess Ganguillet and Kutter, and is ready for use in finding either c, n, R or S when the other three are given. Thus:

1st. Having R, S and n, **to find c.** For example let R = 20 ft, S = .00005, $n = .03$. From the intersection d of slope curve .00005 and radial line $n = .03$, draw* d–20 to the point (20) in oz corresponding to the given R. At e, where d–20 cuts oy, is the reqd c, = 96 in this case.

2d. Having R, S and c, **to find n.** For example let R = 20 ft, S = .00005, $c = 96$. Through the points R = 20 in oz, and $c = 96$ in oy, draw* d–20 to cut curve .00005. n (= .03) is found by means of the radial lines nearest to the intersection, d.

3d. Having S, n and c, **to find R.** For example let S = .00005, $n = .03$, $c = 96$. Find curve .00005 and radial line $n = .03$. From their intersection d draw d–20 through the point e showing $c = 96$. Its intersection with oz shows the reqd R, 20 in this case.

---

* Instead of *drawing* these lines, we may use a fine black thread with a loop at one end. Drive a needle either into one of the points R or into one of the intersections, d etc. Slip the loop over the needle. The other end of the thread is held between the fingers and the thread is made to cut the other points as reqd. The diagram should lie perfectly flat, and the string be drawn tight at each observation, in order that friction between string and paper may not prevent the string from forming a straight line. Or the free end of the string may rest on a pamphlet or other object about ½ inch thick, to keep the string clear of the diagram. Special care must then be taken to have the eye perp over the point observed.

4th. Having R, c and n, **to find S.** For example let R = 20 ft, c = 96, n = .03. Through R = 20 and c = 96 draw d-20. S (.00005) is found by means of the curves nearest to the point d of intersection of d-20 with radial line n = .03.

The following addition to Kutter's diagram, proposed by Mr Rudolph Hering, Civil and Sanitary Engineer, New York,* enables us **to read the velocity from the diagram.**

Find the sq rt of the reciprocal of each slope to be embraced in the diagram $= \sqrt{\frac{1}{\text{slope per unit of length}}}$. Lay off these sq rts on the right of oy, using the scale of c already laid off on its left In our fig we have so proportioned the two scales that $\frac{c}{\sqrt{\text{recip of S}}} = \frac{1.5}{1}$. *Mark* the dividing points with the *slopes per unit of length.*

On oz lay off the vels to be embraced in the diagram, using the scale of sq rts of R already laid off on oz, and making $\frac{\text{vel}}{\sqrt{\text{R}}} = \frac{c}{\sqrt{\text{recip of S}}}$

1st. Having R, S and n; **to find v.** For example let R = 20 ft, S = .00005, n = .03. From R = 20 draw d-20 to the intersection d of curve .00005 with radial line n = .03. d-20 cuts oy at e, where c = 96. With a parallel ruler join R = 20 with S = .00005 on oy. Draw a parallel line through c = 96. It cuts oz at m, giving the reqd vel, 3.03 ft per sec.

2d. Having R, S and v; **to find n.** For example let R = 20 ft, S = .00005, v = 3.03 ft per sec. With a parallel ruler join R = 20 and slope .00005 on oy. Draw a parallel line through v = 3.03. It cuts oy at e, where c = 96. Through R = 20 and c = 96, draw d-20 to cut curve .00005. The point d of intersection, being on radial line n = .03, shows .03 to be the proper value of n.

Any line drawn to the curves from R = 3.28 ft or 1 metre, is one of the radial lines used in making the diagram. It therefore necessarily cuts all the slope curves at points showing the same value of n.

3d. Having S, n and v; **to find R.** For example, let S = .00005, n = .03, v = 3.03 ft per sec. *Assume* a value of R, say 10 ft. Find curve .00005 and radial line n = .03. Join their intersection d with R = 10 ft. The connecting line cuts oy at c = 82. With a parallel ruler join c = 82 with v = 3.03. Draw a parallel line through slope = .00005 on oy. It cuts oz at R = 27.3, showing that a new trial is necessary, and with an assumed R *greater* than 10 ft.

If R thus found is the same as the assumed one, the latter is correct. If they are nearly equal, their mean may be taken.

4th. Having R, n and v; **to find S.** For example, let R = 20 ft, n = .03, v = 3.03 ft per sec. *Assume* a slope (say .0001). Find its curve, and radial line n = .03. Join their intersection with R = 20, and note the value (89) of c where the connecting line cuts oy. With a parallel ruler join c = 89 with v = 3.03. Draw a parallel line through R = 20. It cuts oy at slope .000058, showing that a new trial is necessary, and with an assumed S *flatter* than .0001. If R is 3.28 ft, or 1 metre, the diagram gives the correct S at the first trial, no matter what S was assumed at starting. With any other R, if the diagram gives the same S as that assumed, the latter is correct. If the two differ but slightly, we may take their mean.

* Transactions of the American Society of Civil Engineers, January 1879.

Table of vels in Circular Brick Sewers when running full, by Kutter's formula, but taking **n** at .015 instead of his .013, in consideration of the rough character of sewer brickwork generally.

When running only half full the vel will be the same as when full but this is not the case at any other depth whether greater or less. At greater ones it increases until the depth equals very nearly .9 of the diam, when it is about 10 per cent greater than when either full or half full From depth of .9 of the diam the vel decreases whether the depth becomes greater or less At depth of .25 diam the vel is about .78 of that when full; and then diminishes much more rapidly for less depths. All this applies also to pipes.

The vel for any fall or diam intermediate of those in the table can be found by simple proportion. Original

A vel of 10 ft per sec = 600 ft per minute = 36000 ft, or 6 818 miles per hour. About 5 ft per sec is as great as can be adopted in practice to prevent the lower parts of the sewers from wearing away too rapidly by the debris carried along by the water.

Art. 23. The rate at which rain water reaches a sewer or culvert, etc. **Burkli-Ziegler Formula.** See "European Sewerage Systems," by Rudolph Hering, C. E., in Trans. Am. Soc. C. E., Nov. 1881.

$$\text{Cub. ft. per second per acre, reaching sewer} = \text{A coef according to judgment} \times \text{Av. cub. ft. of rainfall per } \textbf{second} \text{ per } \textbf{acre,} \text{ during heaviest fall.} \times \sqrt[4]{\frac{\text{Av. slope of ground in feet per 1000 ft.}}{\text{No. of acres drained}}}$$

Coefficient, for paved streets, 0.75; for ordinary cases, 0.625; for suburbs with gardens, lawns, and macadamized streets, 0.31.

Note that 1 inch of rainfall per *hour* may be taken as equivalent to 1 cubic foot per second per acre. See Conversion Tables, pp. 235, etc.

Example. If an area of 3100 acres (nearly 5 square miles), with an average slope of 5 feet per 1000 feet, receives a maximum rainfall of 3 inches per hour, then, assuming a coefficient of 0.5, the rate at which the water would reach the mouth of a sewer at the lower end of the 3100 acres would be

$$0\,5 \times 3 \times \sqrt[4]{\frac{5}{3\,1\,0\,0}} = 0\,5 \times 3 \times 0\,2004 = 0.3006 \text{ cubic ft per second per acre;}$$

or 0 3006 $\times$ 3100 = 931.9 cubic feet per second, total.

Let the grade of the intended sewer be say 4 feet per mile; and, to avoid excessive wear of its brickwork by debris swept along by the water, let its velocity be limited to 6.3 feet per second, which may be permitted on occasions as rare as rains of 3 inches per hour, although, for tolerably constant flow, where liable to debris, it should not exceed about 5 feet per second.

Find, in table opposite, the diameter, 14 ft., corresponding, as nearly as may be, to a velocity of 6 3, and to a grade of 4 feet per mile. The area is 154 square feet. Hence, 154 $\times$ 6.3 = 970 cubic feet per second = capacity of sewer. To allow for deposits in the sewer, make the diameter say 14.5 or 15 feet.

Table of least velocities and grades for drain-pipes and sewers in cities, in order that they may under ordinary circumstances keep themselves clean, or free from deposits. (Wicksteed.)

Diam. in Inches	Vel. in ft per Min.	Grade, 1 in	Grade. Feet per Mile.	Diam. in Inches.	Vel. in ft per Min	Grade, 1 in	Grade. Feet per Mile.

Weight per foot run **of glazed terra cotta pipes** for drains, etc. **prices** per foot run adopted by the United Sewer Pipe Makers of the United States, March, 1887. For discounts, see Price List.

Drain pipe, with socket joint						Sewer pipe, with sleeve joint					
Bore	Wt	Price	Bore	Wt	Price	Bore	Wt	Price	Bore	Wt	Price
ins	lbs	$	ins	lbs	$	ins	lbs	$	ins	lbs	$
2	4	0 14	6	18	0.30	15	45	1.25	30	150	5.5
3	7	0 16	8	22	0 45	18	65	1.70	36	195	7.0
4	10	0 20	10	30	0 65	21	89	2.50	42	203	8.5
5	12	0.25	12	33	0 85	24	100	3 25	48	230	10.0

The joints are filled with cement mortar; or, when used for drainage only with clay. Drain pipes (3 to 12 ins bore) are about $\frac{3}{4}$ inch thick. A bend or branch costs about as much as from 3 to 5 feet of pipe. The 48-inch pipes are about 2 ins thick.

Art. 24. When the area of cross section of channel is reduced at any point, as by a dam (Fig 33, p. 576) or by narrowing it, either at its sides (Fig 32) or by placing in it a pier etc. Fig 34; a portion at least of the force of grav (which would otherwise be giving *vel* to the water up-stream from the point where the obstruction takes place), causes *pressure* against the dam etc. This pres maintains the up-stream water at a higher level than

would otherwise have. Said water is then practically in a reservoir; *i e*, it has less vel and greater pres than before. If the reservoir has no outlet, there is *no* vel; and *all* of the head, or force of grav, acting on the water is expended in *pres.*

But if there is an outlet, as over the dam, or between the piers etc, a portion *c o*, Figs 31, 33, 34, of this pres or head, is expended in giving *vel* (or an acceleration of vel) to the water escaping by that outlet; after which only so much head (in the shape of surface slope) is needed as will overcome the resistances of the channel down-stream from the obstruction, and so *maintain uniform* the vel given to the water by the head *c o*.

Where a large canal, such as those intended for navigation, is fed from a reservoir, the fall *c o* in feet is approximately

= mean velocity² in canal, in feet per second, × .017;

and in smaller canals, such as mill courses,

= mean velocity² in canal, in feet per second, × .02.

The abruptness of the fall may be diminished by rounding off or sloping the edges of the piers, or the corners at the sides of the channel (Fig 32) or the approach to the dam.

Fig 33 is a cross section of **Clegg's dam,** across Cape Fear River, N. C. It is from measurements made by Ellwood Morris, C E; by whom they were communicated to the writer. The dam is of wooden cribwork; and its level crest, 8 ft 5 ins wide, is covered with plank; along which the water glides in a smooth sheet, 6 ins deep, (at the time of measurement). At the upper end of this sheet, and in a dist of about 2 ft, a head *c o* of 9 ins forms itself, as in the fig.

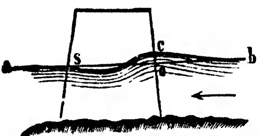

Fig 34

HOISTING, CONVEYING AND EXCAVATING MACHINERY

We here treat of the handling or transferring of objects or materials from place to place, as well as of excavation where that is involvd. (For Dredging, see p 581.) We endevor to outline the varius devices available that are of considerable use to the C E, together with their characteristics and general utility, without troubling too much about mechanical details.

0.1. Classification

We present first, in sections 1.0, 1.1, etc, the details of cranes and derricks and excavators in general, because to describe machines of all possible or even of all usual existing combinations would require many times the space here used. These details may be classified and are treated as follows:—

1.1, the grabbing, holding or digging device; such as the hook, sling, magnet, skip, scoop, bucket, scraper, skimmer, clam-shell, orange-peel, shovel, etc,

1.2, the means for connecting the source of power to the load; such as rope (hemp or wire);

1.3, the mast and the boom, jib, etc, for making possible the moving of the load closer to or farther from the pivot;

1.4, the means for rotating the load; such as a pivoted mast or post, bull-wheel, circular gear, etc;

1.5, the means, if any, for moving the machine over the ground; such as skids, rollers, wheels, caterpillars, etc;

1.6, the hoist, (gearing, drums, etc); and the power itself, such as animal, steam, gas, gasoline, oil, Diesel, comprest air, electric motor, or combinations of them.

0.2. Capacities and Utilities

of some of the machines as a whole, are given under 1.1 (to 1.19 incl); giving further descriptions of details, as cable, booms, power and movement over ground, in secs 1.2 to 1.6

0.3. Convertible Machines

in which different grabbing, holding or digging devices may be applied, are generally available, and in addition, machines may be made up of almost any combination of details from 1.1 to 1.6 inclusiv.

0.4. Other Complete Machines

such as elevating devices, cableways, conveyors, trenchers, back-fillers, etc, are treated in secs 2 to 9 inclusiv.

1.0. DETAILS

1.1. HOOKS, SLINGS, GRAPPLES, BUCKETS, SHOVELS, etc

Hooks, tho essentially very simple, should be scientifically designd, and should be made of material, such as soft steel forgings, that will yield before cracking, thus increasing the chance of detecting complete failure before it occurs. They may have many special forms for special purposes. Some hooks are provided with safety shackles or catches to prevent the load from slipping off; some with catches that may be releast for dropping the load suddenly, as in operating "skull-crackers" for breaking concrete or castings. Hooks are often

made double, reducing eccentricity of loading and affording more room for chains or slings. Two hooks may be framed with a pivot, like ice-tongs, or the two (or more) hooks may hang loosely from rods or chains, so that when separated the width or length of the load and attacht to it, they exert a hor component tending to prevent slipping. Hooks or chains may be attacht in varius ways to **platforms** or **skips**, on which the load (earth, rock, merchandize, packages, etc) may be placed. See also 1.18, scrapers. Hooks are depended upon for most of the work on building erection.

Slings are much used for hoisting. These are merely chains or rope with or without hooks or eyes, sockets or rings. The sling may consist of an endless loop of wire rope only wrapt around the object to be hoisted, tho more usually the ropes are fastend around eyes, Fig 1, one large enough to pass the other thru, or at one end they may be attacht to a hook. **Bridle slings** consist of a length of rope with a hook at each end and the middle past around a socket. When hoisting metal beams, etc, thin pieces of wood must be placed between the beam and the rope or hook. The wood crushes and increases the friction, reducing the danger of slipping. The two lengths should form an equilateral triangle with the beam or other object held hor'y. **Caution:** increasing the spread materially greatly increases the stress and danger of breaking. Several bridge companies have largely used chains of ½" to ¾" with rings at each end.

The first two items treated under 1.1 (hooks and lifting magnets) are not limited in their use to cranes or derricks, being often of use in other types of apparatus.

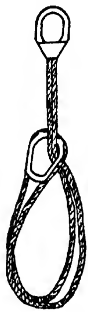

Fig. 1

1.12. Lifting Magnets

Electro-magnets have a number of advantages where direct current electricity is available, and where iron or steel are to be handled, especially scrap, or where many small or irregular pieces are to be handled. Iron or steel may be pickt up, and lowerd or releast, or dropt, all with fewer if any extra men for attaching and detaching. Magnets can handle and drop skull-crackers efficiently. They can lift iron or steel which is under snow, or when packt in boxes, or when hot. Of course, reliable current is essential for safety, tho automatic underhung hooks may reduce the danger. Such hooks may be regularly used for carrying loads of fairly uniform shape from place to place while current is shut off. A single hoisting line is sufficient where safety hooks are not used. Magnets are of course useless for anything but ferrous metals.

The **lifting capacity** depends largely upon the form of the iron or steel to be handled. A magnet 20" diam, will lift 3600 lbs of billets or slabs, and one of 65", 50,000 lbs. Skull-crackers of 2/3 of these weights may be lifted; but only about 1/20 to 1/30 of these wts of scrap iron. The great ease of handling irregular scrap, etc, compensates for the reduced attraction. The current consumption at 220 volts will range from 6 to 60 amperes. (From Material Handling Cyclopedia, Simmons-Boardman Publishing Co.)

1.12a. Vacuum Lifters have been used for seizing non-ferrous mat'ls. They are similar in operation to the pneumatic fingers used on printing presses for handling sheets of paper one at a time, and may be used on any material such as copper, zinc, wood, wall-board, etc, as well as iron or steel, having a smooth surface. The lifting capacity depends upon the area of the suction cups employd and may be so com-

puted. A valve controls the vacuum or air pressure for seizing or releasing the mat'l to be handled.

1.13. Buckets

The preceding devices, except perhaps platforms or skips, sec 1.1, cannot well handle granular mat'l, as earth, coal, ore, loose rock, etc, and for these buckets are of use. We first consider those that **can not dig**, and must have the mat'l deliverd into them, as by hand shoveling. Nearly all such buckets may be hoisted by a single hoisting line, to which they are attacht. The unloading is controld by a latch or trip operated by hand at the bucket, or by a light line puld from the hoisting engin or near by, or by a second line operating levers or doors.

1.131. Turn-over buckets, one type of which is ill'd in Fig 2, are so balanst that when not full they assume an upright position, but when loaded the tendency is to turn over. This is resisted by the latch or trip. Thus, after filling, the bucket is hoisted and swung and lowerd over the desired point, and the latch is tript. The bucket turns over, drops its load, and then automatically rights itself and relatches ready for the next loading. These buckets are made with either straight sides, curvd back or bottom, or as a vertical cylinder. For contractor's work they are made in sizes of 1½ cu yds cap down to ½ cu yd or less. It is difficult to deliver the contents of turn-over buckets exactly where wanted.

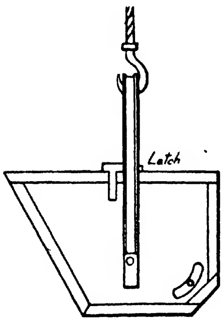

Fig. 2

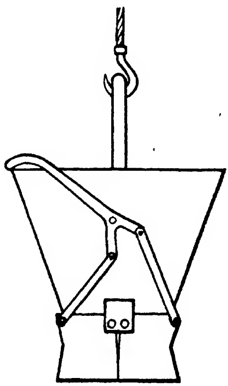

Fig. 3

1.132. Bottom-dump buckets, one of which is ill'd in Fig 3, are made in many forms and with many types of doors or hoppers operated with varius arrangements of levers too numerous to mention and too unimportant to describe in detail. In some types the load is dumpt all at once; in others the discharge is controllable, some having the hopper door designd especially for dumping (concrete, *e.g.*) accurately into narrow spaces. Capacities range from abt 2 to 3 cu yds down to 1 cu yd or less.

1.14. Grabs; Clam-Shells & Orange-Peels

Grabs may be described as buckets **capable of digging**, and those for land excavation are much the same as for dredging. See p 581*e*, &c, including paragrafs 45, 54 and 56.

1.141. Utility. Grabs may be used for either plain lifting or the handling of varius objects, or for digging loose or soft mat'l, as earth, coal, sand, etc, and to a certain extent both together, as where old timbers or debris are encountered in digging; but not hard mat'l. **Care** should be taken to obtain the machine best suited for the servis desired, especially a correct ratio of bucket-closing force to lifting force, which depends upon the number of sheavs and "parts" of hoisting cable (see sec 1.2) and leverage of arm (p 581*e*, paras 38, 39 and 40), shape of bucket bottom, teeth, etc. A bucket may cut so deeply that it becomes overloaded and the hoisting is retarded, or the cut may be so light that there is much waste motion. (See Engg-Contracting, '32 Aug, p 193). Clam-shells are obtainable with **electric motor** mounted on a bucket, to force the closing of the bucket. This has the advantage of a surer bite into the mat'l, and may be used with hoists having only one line, or on overhead tracks, tho the addition of the motor and wires increases complication.

1.142. Operation. As in dredging, the bucket is hoisted and lowerd, and opend and closed by means of two lines of cable. The rotation of the boom is accomplisht by the engin acting on a bull-wheel (p 581*k*, para 60), pivoted mast or circular gear (sec 1.4).

1.143. Capacities of land grabs usually employd range from ½ cu yd to 3 cu yds by ¼ cu yd diffs, and the corresponding wts are from abt 2000 lbs to 7000 lbs. Clam-shells of 16½ cu yds cap have been built, weighing 28,000 lbs

1.144. Dimensions. The following approx figures are taken from the catalog of a large mfr.

Bucket cap, cu yds	½	¾	1	1¼ to 1½
Boom length, ft	30	38	40	40 to 45
Max clear lift of bucket, ft	20	28	30	30 to 35
Max ht of boom, ft	35		43	47 to 52
Max ht of boom, lowerd, ft	12	12	12	15 15

1.145. Special forms, usually made up of bars or prongs, are used for handling **long materials** in quantity, as timbers, rods, pipes, etc.

1.146. Miniature or dwarf orange-peel buckets may be had small enough to dig holes only a foot in diam, for wells, test holes, etc. Owing to their small capacity, they may usually be operated by **hand**; but unless the mat'l is very soft, they require a heavy "hammer" (wt) mounted so as to slide on a vert rod above the bucket, to force the orange-peel points into the mat'l.

1.15. Dippers and Shovels

Shovels for land excavation, Fig 4, are much the same as shovels or dippers for dredging. **See p 581*j***, etc, paragrafs 58, 60-63 incl.

1.151. "Crowding" devices used to force the "stick," *T*, up or down thru the boom, *B*, may be operated either by a **separate engin** or motor on the boom, as usual in dredging, or the gearing may be operated by either **cable or chain**, *N*, driven from shafts from the main engin or motor in the cab. There are arguments in favor of and against each, but the differences seem to be slight

1.152. Capacities. The usual small shovels for the local contractor have a cap around 1 cu yd, the smallest holding ⅜ cu yd, and sizes up to 2 or 3 or more cu yds are available for larger operations. Special machines for strip mining used by the Electric Coal Cos at DuQuoin, Ill, had buckets holding 15 cu yds. (Eng News-Rec, '32 May 5).

1.153. Lips and Dipper Teeth. Manganese steel is largely used. Even so, dippers working in boulders in stream beds may wear out one set of teeth every 8 hours. Mr. George Sykes reports (Eng News-Rec, '33 Feb 16, p 215) that by welding hard surfacing to the bucket teeth with an alloy of cobalt, chromium and tungsten, their life can be increast more than ten times. Stelite is another mat'l used.

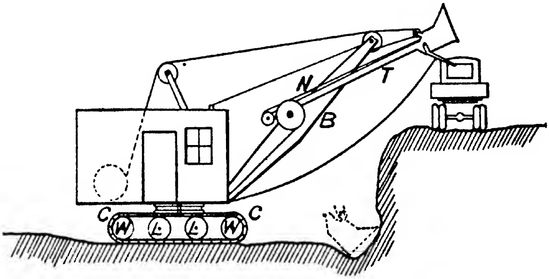

Fig. 4. Shovel

1.154. Utility. Shovels will handle much the same mat'ls as grabs (sec 1.14), and will dig much harder mat'l, even loose rock or ore They will easily handle mixtures of earth and debris, and are of great servis in digging ore or coal, tearing up road surfaces, old foundations, floors, walls, in excavation of basements, grading, sewer work, quarry excavation and gravel pits, irrigation and RR work. Special compact shovels for **underground work** are often satisfactorily used for excavating subways and tunnels.

1.155. Operating Speeds range as follows, the figures being in seconds for each operation of a complete cycle:—

	Loading	Swinging	Dumping	Returning	Total
Maximum*	16	7½	5¾	7¼	34
Average†	9.6	6.0	2.4	6.2	24.2
Minimum*	7	5¼	2	5½	21

the maxima being usual for poorly blasted rock, and the minima for good common mat'l.

1.156. Delays. The following are taken from figures given by Andrew P. Anderson, Roads & Sts, '34 July, p 255 *et seq*, obtaind from 51 power shovel highway jobs:—

Minor delays, per cent		Major delays, per cent	
Hauling equipment ..	9.9	Weather	14.9
Shovel, mvg, repairs.	9.1	Shovel, mvg, repairs..	9.5
Miscellaneus	14.2	Miscellaneus	6.0

* Eng News-Record, '29 Nov 28, p 860.
† Roads and Streets, '34 July.

1.157. Effect of Material on time req'd to load dipper; good earth, 5.7 secs; earth and some rock, cemented mat'l, 8.4 secs; poorly blasted rock, 10.3 secs; very poorly blasted hard granite, 16.7 secs.

1.158. Dimensions. The following figures are averages; the smaller sizes being taken from mfr's catalogs, while the larger sizes are those of RR power shovels from Mat'l Handling Cyclopedia by Simmons-Boardman Pub Co.

Capacity of dipper, cu yds	2/3 to 1	2½ to 6
Length of boom, B, ft	18 to 22	24 to 31½
Length of dipper handle, T, ft	14 to 17	17 to 20½
Dumping radius, max lift, ft	24 to 27	26½ to 32
Maximum height of cut, ft	19 to 21	
Maximum dumping height, ft	13 to 15	16 to 18½
Digging radius, ft	27 to 29	26 to 33
Height of boom at max angle, ft	24 to 30	
Max height, boom lowerd, ft	12 to 15	

In a 3/8 cu yd full revolving shovel,

with angle of boom	40°	60°	with angle of boom	40°	60°
max dumping ht, ft	12	17	max digging rad, ft	21½	19
max dumping rad, ft	18¼	14¾	depth of digging, ft	3½	2
max digging ht, ft	16½	21¾	swing of boom, ft	15¼	11

Some of the smaller machines may be transported on a heavy duty motor truck.

1.159. Miniature Shovels or Loaders are available, of somewhat different designs, but very compact, being but little if any taller than a man, some of them having no slewing device and depending upon their caterpillars for changing direction, yet they are mostly over ½ cu yd capacity.

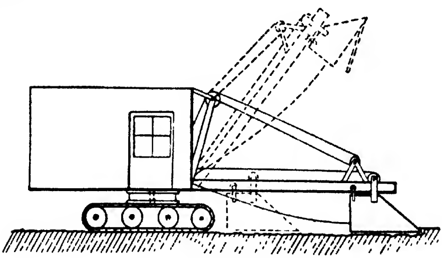

Fig. 5. Skimmer

1.16. Skimmers

A skimmer, skimmer scoop, or hor'l crowd shovel, Fig. 5, is akin to a shovel or dipper, but with more restricted movement. A dipper stick is not used, the skimmer bucket being arranged to be slid long'ly along the boom by cable from one of the engin drums. When digging, the boom is kept level or at grade desired, and the bucket is pulled out along the boom until full, when the boom is raisd and

turnd hor'y until over the truck or place where the mat'l is wanted. The load is dropt by either tilting the bucket down, or by unlatching a pivoted bottom.

Capacities from ½ to abt 2 cu yds. A ¾ cu yd machine can handle 400 to 500 cu yds or over of loose dirt per day.

Utility is limited chiefly to operations that might be called "skimming", *i e*, shallow excavating along the surface, tearing up old roads or highways of almost any mat'l. The machine is simpler than the dipper shovel with its boom and stick, and more easily levels off large surfaces with satisfactory accuracy.

Dimensions. In a ¾ cu yd machine; length of boom, 16'; lift, 16'; min ht of machine, 15'; max ht, boom raisd, 23½'; hor length of cut, 12½'.

1.17. Pull-Scoop,

also called Pull Shovel, Goose-Neck, Trench Hoe, Back Digger, or Back Hoe.

Pull-scoops, Fig 6, may be regarded somewhat as dipper shovels in reverse, except that the "stick", *T*, does not pass thru the boom, *B*, but is pivoted to the outer end of the boom, and the cutting bucket, *K*, is pivoted to the outer end of the stick, facing back toward the engin. It dumps by tilting. Pull-scoops are readily interchangeable with skimmers, sec 1.16.

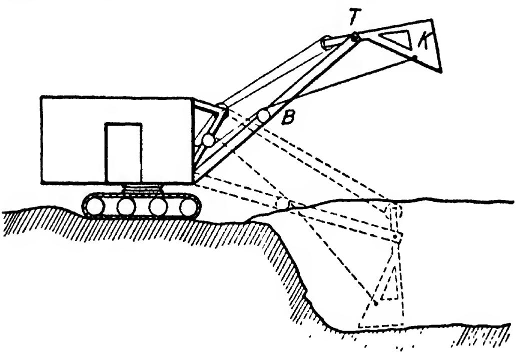

Fig. 6. Pull-Scoop

Capacities from abt ¾ to 2 cu yds. In hard digging in trench work, all day may be req'd for one 12' length of pipe; in easier ground, enough may be dug for 10 or 15 lengths.

Utility. It is useful for digging pipe, sewer or other trenches, as deep as 25'; but can be swung hor'y like a shovel or skimmer, so as to excavate areas as well. It can cut thru hard slate, shale, blasted rock or a foot of frozen dirt. See also 7.6, trenchers and ditchers. A hook on the bucket may be used for laying pipe.

1.18. Scrapers

1.180. Scrapers are of many types and are operated in a number of ways. They consist essentially of a strong box, usually open at one end and more or less on top, with a cutting edge at the open end of the lower side, and means for dragging along the ground. When the scraper reaches its destination, it is dumpt so as to spil out the mat'l. Scrapers may be puld by horses, tractors, cables or almost any other means.

Their **utility** lies in clay, soft shales, loam, sand, gumbo, gravel, etc. They become troublesome in wet mat'l, or mat'l containing large boulders or snags. Their size is varied according to the power used, and their form according to the kind of mat'l and the service to be renderd, such as gutter-work, back-filling, ditching, grading. In some types a **double bottom** is employd, the outer shell of which may be removed when worn thru, before wearing out the main body. In others **ribs** are attacht to the bottom, tho they seem to be of doubtful advantage.

Length of haul. As they are excavating as well as transporting devices, too large a percentage of their time should not be spent for hauling, so that it becomes better, if the haul is over 100′ or so, to resort to some other device or combination, such as power shovels and wagons or trucks, each of which may be kept working almost continuously at its own specialty. The economical limit of haul is variously set at anywhere from 100′ to 250′, tho some mfrs claim as high as 1500′.

1.181. Horse-drawn drag-scrapers or slip-scrapers, and wheel-scrapers. See pp 1029-1031...Art 12. (Note the necessity for pro-rating costs from the assumed $1 per 10-hour day). In mfr, the material of the scraper should have been bent or workt into shape when cold.

1.182. Tractor-drawn scrapers (on wheels or caterpillars) to be puld by tractors, may be very much larger than those puld by animals. Some are arranged to be drawn in trains of 3 or 4 units. Nearly every mfr has his own special form or device. One type is crescent-shaped; another is cylindrical in form (the axis of the cyl lying hor'y at rt angles to the line of travel) having an open side with a cutting edge in front, the dumping being accomplisht by permitting the cyl to rotate; another is bottomless, the earth being dragd along with it; while still other types, by means of a moveable lower lip, gather the mat'ls into a large bin, from which it may subsequently be dumpt or forst out. Some are reversible and may be dumpt by backing up. Some are controld from the tractor by cords or cables. Not a few are provided with **power control,** using oil or air to adjust and maintain the ht of the cutting edge, so as to control depth of cut, and either to dump all at once or distribute over a distance.

Capacities range from 1 or 2 cu yds up to 6, 8 or 12. The rate of earth handling varies too greatly with the size, length of haul, character of ground, speed of tractor, etc, to be stated even approx'y; but may ordinarily be estimated fairly closely by computation. Some mfrs have prepared tables or diagrams which include most of the factors. Most scrapers will drag along with them considerably more than their computed capacity.

Sizes of several makes of tractor-drawn scrapers; cutting width, 5′ to 10′; ht at back, 22″ to 48″; wts, 750 lbs to nearly 6000 lbs, and as high as 17,000 lbs in certain forms. Tractors to pull such scrapers must be capable of 10 to 30 HP or more; those of 12 cu yds cap, from 75 to 100 HP.

1.183. Derrick- or Crane-operated scrapers are usually called **Drag-Line Scrapers or Drag-Line Excavators.** They are much the same as where used for dredging; see p 581*b*, paragrafs 24, 25, 27 and 28. For this work, some buckets are constructed for rear or **back dumping** by being provided with a door or flap controld by a latch, as in dipper buckets, but they are usually dumpt by releasing the drag-line.

For **capacities,** see "Dimensions", below.

Utility. As an excavator, the drag-line is perhaps more generally useful than any other excavating machine. The bucket is lighter than other types, and this combined with the direct pull of the drag-line, makes possible a lighter and longer boom. In addition, the operator, by pulling the bucket toward the crane and then releasing, can throw the bucket beyond the end of the boom some 30% farther than the length of the boom. It can handle all loose earthy mat'ls, and do good work in blasted rock, or in handling boulders, stumps and roots. It has exceptional range of high and deep cuts. At Taylorsville (Miami Conservancy) machines excavated as deep as 63', and as high as 37'. It is accurate enough for effectiv loading of trucks and cars; and is largely used for mine stripping, drainage and canal excavating, levee building and trenching. It can build its own "trackway" ahead and clean up behind. Thus, in Miami Conservancy work, machines crost shallow rivers by maintaining "moving islands" for themselvs, which they kept adding to ahead as they crost, while they restored the river channel by digging out behind. About the only disadvantage is a tendency to cut irregularly, leaving an uneven surface. In the Miami work this was largely corrected by going over the ground afterwards with heavy drag platforms or frames. This resulted in an earth surface within 6" of that intended; a max variation of 1' in rock; and 2' under water.

Dimensions. The figures below are averages taken chiefly from the catalogs of well-known mfrs.

Capacity, cu yds....	½	¾	1	1¼	2½	5	10
Boom length, ft....	30	38	40	40	85	155	160
Dumping reach, ft, boom 25°.........	32	39	42	42	92	164	
Add'l throw beyond dumping reach...	13	13	13	13			40
Dumping, ht, ft, boom 40°.........	15	20	21	22	45	71	
Max ht, boom lowerd, ft...... ..	11½	12	12	15			
Depth of cut, ft....	16	18	19	21	58	75	
Pull on bucket, tons	6	8	10½	12½			
Drag-line speed, ft/min	110	100	116	110			
Rotating speed, rev/min	5¼	3½	3½	2¼			0.85

Machines up to and including 1¼ cu yd cap can usually be transported on flat-car without dismantling.

Operation. See p 581*c*, para 25. Drag-line scrapers can be used in many ways. A favorit method is to arrange them in "series", so that one can pass mat'l on to the next, and so on. For suggestions and accounts of plans adopted, see Eng News-Rec '31 Apr 16, p 636, etc, and '32 Jun 2, p 796, etc. **Speeds** range for the usual small machines from 200 cu yds/8 hrs for loading into wagons, 250 to 500 for excavation, 350 to 600 for ditch cleaning and RR drainage. **Delays** on the Miami Conservancy District: Englewood dam, 1920, from

1.7% to 18.1% in different months, but with the av for the season 7.7% for steam machines, and 7.8 for electric. On the Huffman dam, 1921, (electric), 21.6%. In all of these "waiting for cars" was responsible for half or more of the delay.

1.184. Cable-operated scrapers are treated under 4.1.

1.19. Pile Driver

attachments, consisting of vert hammer gides, may be attacht to the ends of the booms, and the hammer operated by the hoisting line.

1.2. CABLE

1.20. Hemp rope is seldom used for any prolonged hoisting or conveying operations, **wire** rope being used almost exclusively for such work. **See also** pp 1386-8 incl.

1.21*. Hoisting cable should be of a flexible type, hemp center, plow steel, known as 6 × 19, Lang lay. **Life** is about 50% greater than for drag-line (below).

1.22*. Drag-line cable as above, but with wire or wire-rope or wire-rope center. **Life;*** cable hauld 45,000 to 60,000 cu yds at a **cost** for cable of $2.06 to $1.22/1000 cu yds of excavation.

1.23. †Use and Care of wire rope are very important, the replacement cost being estimated as betw 50 and 80% of all maintenance. Bad handling may increase the cost 2 to 4 times, or even 10 times* the cost under careful handling Care should be taken to unreel a shipment of cable as a spool of thread is unwound, and to keep the unwound cable out straight and under control, so that it cannot slip out of hand and kink. It should be clampt before cutting to prevent untwisting. Operators are likely to be indifferent and to cause great damage to cable quite unnecessarily, especially by jerking or kinking The winding drum and all sheavs over which the cable passes should be of ample diam, from 400 to 500 times the diam of the individual wires, and kept in good alinement, the drum groovs should fit the cable, and if possible there should be not more than one layer of cable on the drum. Frequent lubrication is important, especially when the rope is to be idle for weeks or months, exposed to the weather A cable showing more than 6 broken wires in any foot of its length, or has 3 or more adjacent broken wires in the same strand, should not be used. (J. Feld, Civil Engg, '34 Dec, p 647). To minimize enforst idleness of machines, extra lengths of cable should be kept on hand ready for immediate use. There is probably no economy in obtaining any but the highest grade.

1.3. MASTS AND BOOMS, CRANES AND DERRICKS

Masts and booms, except where part of a mfd hoisting or excavating unit, are often specially built for the work in hand, and are usually of wood or steel. **Caution.** They must of course be carefully designed as long colums (but see recommended dimensions under 1.311 and 1.312, below)

---

* Most of this information from "Construction Plant, Methods and Costs", by Chas. H. Paul, Miami Conservancy District, Dayton, Ohio, 1925.

† Chiefly from article by Herbert MacMillan, Eng & Contr'g, '31 Jul, p 175; and the Miami report above.

not neglecting ample allowance for overloading due to sudden stoppage of a descending load by the hoisting cable, accidental lateral impact, and, in the case of booms, for the wt of the boom acting on itself as a beam, making further allowance for side stresses due to sudden stoppage of the boom while being lowerd.

1.30. Materials

1.301. Wood is often used for masts and booms for moderate loads. Iron or steel **fittings** may be obtaind, such as foot blocks, mast steps and tops, boom seats, caps, stiff-leg straps, boom bands, back-leg bottom plates, sheavs in blocks ready for framing to the timber, etc, for the complete construction of derrick frames. See also 1.31.

1.302. Steel masts and booms are usually built-up structural members with latticing.

1.303. Aluminum alloy booms have been built as long as 175′ or more.

1.31. Derricks

Generally speaking, a derrick is a hoisting device in which the mast (carrying sheavs at or near the top over which pass ropes controlling the load and the end of the boom) is kept vert by means of guys or struts, and is not capable of movement over the ground without dismantling. (Towers used for oil wells and for pile driving are called "derricks" also, even tho they are usually stiff enough to require no lateral supports at their tops).

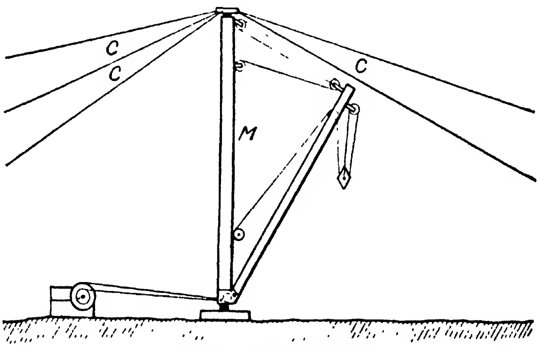

Fig. 7. Guy Derrick

1.311. In a **Guy** derrick, Fig 7, the mast, *M*, is kept vert by means of wires or cables or rods, *C*, *C*, *C*, in tension. Theoretically, three should be sufficient, but it is well to have five, so that in case one breaks, the derrick will not fall. The safe sizes for such guys may be computed, knowing their inclination, the wt and angle of the boom, and the loads to be handled, making ample allowance for jerking of

the load. The following dimensions for wooden guy derricks are recommended by Mat'l Handling Cyclopedia;—

Capacity Tons	Mast	Boom
1½	34′ × 8″ × 8″	25′ × 6″ × 6″
6	50′ × 12″ × 12″	40′ × 10″ × 10″
16	60′ × 16″ × 16″	50′ × 14″ × 14″

Probably 40-ton capacity derricks, and even smaller, are better made with steel masts and booms.

1.312. In a **Stiff-leg** derrick, Fig 8, the mast, *M*, is kept vert by two or more stiff members, *P*, *P*, inclined at abt 45°, spaced abt 90° in plan. For light or "home-made" derricks, these may be simple timbers, similar to the mast and boom, but are usually reinforst at their middles either by additional struts, *S*, *S*, to the ground, or by added thickness or "trussing", for they must be able to sustain their own wt as inclined beams, and to take compression, and are usually nec'y longer than the mast. The following dimensions for wooden stiff-leg derricks are recommended by Mat'l Handling Cyclopedia;—

Capacity Tons	Mast	Boom
1½	16′ × 8″ × 8″	25′ × 6″ × 6″
5	26′ × 12″ × 12″	40′ × 10″ × 10″
12	33′ × 16″ × 16″	50′ × 14″ × 14″
33	36′ × 22″ × 22″	55′ × 20″ × 20″

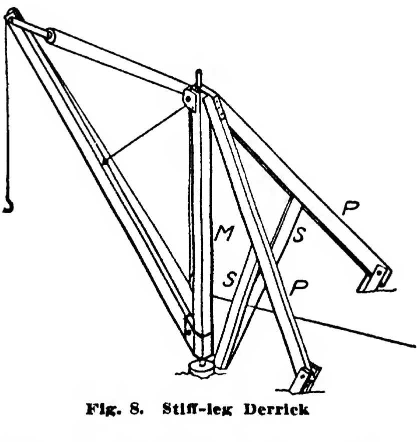

Fig. 8. Stiff-leg Derrick

The largest of three stiff-leg derricks used in the construction of the Boulder (formerly Hoover) dam, had a boom length of 180′; mast ht, 75′; legs of abt the same length, since they bore almost hor'y against the canyon walls; and had a capacity of 12 tons. (Eng News-Rec, '34 Jun 28, p 832). Others have capacities of 50 tons or more.

1.3121. A **Jinniwink** is a stiff-legd derrick in which the lower ends of the legs and of the mast are attacht to the ends of a hor T-shaped frame of timbers, which can be lasht to the floor of a building in course of construction, and then moved about from place to place as req'd. Capacities, 3 to 5 tons.

1.313. A **Gin Pole** consists of a single pole, slightly inclined and supported by four guys. The hoisting line passes over a sheav near the top. It can handle loads only vert'y under the upper end. It can be readily rigd up on the job, and so may frequently be of use, as may also

1.314. Shears, which consist of two poles mounted like the A-frame of a dredge, and similarly inclined, being held in position by a back-guy.

1.315. Tripods, consisting of three stiff legs, need no guys, but can handle loads only well within the space embraced by them. These are dangerus on a hard smooth surface unless the feet of the legs are properly tied to each other to prevent spreading.

1.316. Sulkies. It may be worth while in the case of small rigs (tripods, shears, etc) to mount a pair of wagon wheels on an axle against two of the members, the axle being horizontal. By tipping the outfit over and bringing the wheels to the ground, it may be more readily moved from place to place.

1.32. Cranes

In the predominating type of crane there is no tall mast or tower requiring guying. The hoisting and boom lines are attacht to the engin or motor or to the base or to an A-frame such as that in dredges, the device being kept upright by virtue of the width of its base and the wt of the engin or motor and cab (mounted well to the rear) and possible counterweights.

Utility. Probably no other type of machine for hoisting, conveying and excavating is more versatil and in more general use. By varying the boom and attachments, nearly all makes can be used, as simple hoists, as shovels (Fig 4), or to handle clam-shells or orange-peels, skimmers (Fig 5), drag-lines, backdiggers (Fig 6), or pile drivers. For their respectiv utilities (except hoists) **see secs 1.14 to 1.18 incl.** **Care** should be taken that the load does not tip the crane. Tipping depends upon the dist of the load from the center of the crane, as well as its wt, and possible jerking by the hoister.

Dimensions, etc. The following data are closely representativ of average practice, there being but small variations between different makes,—

Dipper of bucket, capacity, cu yds..	⅜	½	¾	1
Boom length				
for clamshell or dragline, ft......	25-35			35-40
for shovel, ft....................	16	18	18	18
Dipper stick, for shovel, ft.........	12	14	14	14
Travel speed, 15% grade, mi/hr....		1.6	1.5	1.5
" " 30% grade, mi/hr....		0.4	¾	¾
Overall length, ft..................	9½		11	13
Working weight, thousands of lbs, approx	20		50	60
Swing speed, rev/min..............		4.8	4.6	4.5
HP (gasoline).....................	42	47	70	80

In the cranes "Hercules" and "Ajax" used on the Panama canal (Eng News '15 May 13) there was a tower, from the top of which the boom projected, but it was not guyd, and obtaind its stability from the barge on which it was

mounted. A floating crane of 200 tons cap was used at the Port of Havre (Eng News-Rec, '34 June 14). Cranes of similar design, sometimes referd to as **"Portal Cranes"**, are largely used on docks.

1.321. Jib, Pillar or Foundry Cranes. While some are maintaind upright by means of a post or mast embedded in the floor, they are usually supported at their tops by framing to a wall or to the ceiling or roof. Either an inclined jib or boom is held up by connections to the top of the pillar, in which case a load can be handled only from the boom's end, or else the arm extends hor'y from the top of the pillar, and a hoist (sec 2 2) is mounted on a trolley moveable hor'y along the boom, in which case a load can be handled anywhere within the circle swept by the boom. Jib cranes are usually shop fixtures and have little use in eng'g construction.

1.322. Hammerhead cranes have a boom permanently hor which is mounted on a tower (without guying), the load traveling along it as in jib cranes. These too are generally used in permanent positions, as on docks, supply yards, etc. A notable exception was their use on the towers of the West Bay crossing of the San Francisco-Oakland Bay bridge (Construc'n Methods, '35 Aug, p 33).

1.4. ROTATION, SWINGING OR SLEWING

of the boom is accomplisht in different ways. **In derricks** mere pivots are provided at the tops and bottoms of the masts which may then be swung by hand or by power by means of a bull-wheel, (8' to 16' or more in diam). **In cranes** the boom is usually mounted on the platform or "base" on which is mounted the engin or motor. This platform acts as a turntable, riding on wheels or rollers arranged on the circumf of a circle, and resting on the floor beneath or upon the frame of the car or truck which is provided for motion over the ground. Rotation is effected by the engin or motor driving a vert shaft which extends down thru the platform, carrying a small gear which engages with a large gear mounted on the frame below. Thus there is usually no limit to the angular motion of such a crane, sometimes referd to as a **"whirley"** or **"whirler"**.

1.5. HORIZONTAL MOTION

Many methods are available for moving the hoisting, conveying or excavating machine as a whole, aside from such hor motion as can be obtaind by trolley on jib crane, by changing elevation of boom, etc, depending largely upon the kind of surface to be traverst.

1.51. via Water

Machines mounted on vessels may of course be moved wherever there is sufficient draft. While sometimes it may be practicable to have the boom reach over land, so as to serv for hoisting and conveying, the usual use is for dredging, or excavating under water. **See p 581, et seq.**

1.52. Skids

may be used where the machines are not very heavy, but in view of the many modern methods available, they need seldom be resorted to.

1.53. Rollers

rolling on prepared plankways constitute an improvement on skids in that they greatly reduce friction.

1.54. Flanged Wheels on Track Rails

are a further development and further reduce friction, but require more elaborate preparation. If the ground is hard, the preparation may be easy; but if soft, it may be advisable to construct a track almost as elaborate as for a RR. Indeed, for heavy machines, two standard gage tracks may be advisable or necessary. This is often used for derricks, ordinarily immovable without dismantling. For the building of dams, long buildings, stadiums, elevated RRs, etc, rails may often be laid along the structure. Where two rails may naturally come at different elevations, the framework under the derrick may have legs of correspondingly different lengths.

1.54a. A **Locomotive Crane or Shovel** consists of a crane mechanism (see sec 1.32) mounted on a railroad flat-car or frame, on one or preferably two four- or six-wheeld trucks (usually standard RR trucks), the wheels being driven by power transmitted down thru the central shaft or pivot, from the engin or motor.

Utility. Within reach of a RR track, its uses are approx those of other cranes, being largely used not only for wrecking, but also for digging ditches, taking care of embankments, driving piles, erecting bridges, etc.

Dimensions, etc.

Capacity, tons	15	20	25
Boom length, ft	40	45	50
Speed, mi/hr	2-4	2-4¼	4½
Max grade, %	8½	8½	
Min curv, rad, ft	55	55-60	60
Overall length, ft	25	25	
Weight, thousands of pounds	83	120	142
Swing speed, rev/min	4	4½	4-5
HP (gasoline)	80	97	140

1.55. Wheels on Ground

Metal tires or rims of great width with deep markings are sometimes used with satisfaction where the roadway is fairly good. But it is generally more satisfactory to use

Rubber tires, which are of four main types; (1) solid, (2) "cushion", with a hollow tunnel thruout its length, or other forms of hollowing, (3) "high pressure", using from 50 to 100 lbs/sq in, and (4) "balloon", using from abt 30 to as little as 5 lbs/sq inch in the super-balloon or "doughnut" tires. Where soft or wet ground may be encounterd, the larger tires are preferable, as they exert lower unit pressures on the ground. Apparently, suction greatly vitiates the law stated under "2nd" on p 410, and the grooving or other surface patterns used afford greatly exaggerated roughness, thus greatly increasing the traction of the larger tires over that of the smaller solid and cushion tires, so that the greater **care** req'd for maintenance is well worth while if actually put into effect. There should be careful application or attachment of tire to rim, correct wheel alinement, no overloading, proper air pressure, moderate acceleration and deceleration, no skidding, avoidance of sharp objects in the road, and no high speed with heavy loads or at sharp turns. Where even a small fleet of trucks is employd, there should be one or more men detaild to attend to tires, their inflation, cuts and punctures and loading. Bonuses to drivers for increast tire mileage have proved profitable. Much can be done by a skilful driver to **avoid slipping** (which reduces tractiv effort, increases danger of accident, and increases wear) by applying power gradually when starting, and stopping by applying brakes

carefully and leaving the engin in gear until almost stopt. At any given speed, the **impact** of a solid tire over a given obstacle or road roughness has been found to be abt double that of a balloon tire. **Dual** or double tires, in which two wheels with tires are used side by side in place of a single wheel and tire, are frequently used for rear wheels and for trailers, to carry heavier loads. Additional care is needed with duals to avoid unequal division of the load betw them, as by running the outer one off the edge of a road, or using unequal pressures. As high as 16 doughnut tires are sometimes used under trailers, in which cases equalizing devices are provided to distribute the load evenly.

1.56. Caterpillars, Crawlers

(We here treat only of the running gear that goes by these names. Tractors using caterpillar mechanism are also called "Caterpillars", but are treated in sec 6.44).

1.561. Construction. The caterpillar or crawler running gear consists of two endless bands, *CC*, Fig 4, one on each side of the vehicle, tractor, crane, excavator or other machine to which it may be applied. Each band passes around two large wheels, *WW*, with teeth or sprockets with which it engages, the two rear or front wheels doing the driving. There may be two or more additional wheels, *LL*, on each side, to keep the entire lower portion of the band prest down against the ground. Each band is several ft wide and the length on the ground is 5 ft or much more, giving a bearing surf of 25 sq ft or more, far in excess of what even a large number of balloon tired wheels can afford, thus greatly reducing the penetration of the driving mechanism into the ground and the depth of the resulting hole continually encounterd. Usually each band is made up of a series of plates of hardend steel, linkt together, often provided with transvers ridges, webs, grouters or grousers; but continuus rubber belts have been used as well. In some makes, the metal belts are readily detachable, when the machine may run on its wheels at higher speed. The device is, in effect, a locomotiv running on a cog ry or rack track which is automatically laid on the ground ahead of the wheels and taken up behind them and brought forward again. None of the wheels are arranged for **steering or turning**, and this is accomplisht by retarding the band on one side, and maintaining speed on the other. With one belt held fast, the machine may be turnd 180° in almost if not quite its own width.

1.562. Operation is effected almost invariably by a gasoline or oil engine, with clutch and brake for each band. **Speeds** may range from 2 to 10 mi/hr, but at higher speeds, the machine becomes cumbersome and noisy with much impact due to the flapping of successiv plates onto the ground.

1.563. Horse-powers and weights depend upon the type of machine to which the caterpillar is applied, such as tractor, excavator, etc, *q v*.

1.564. Utility of caterpillars is very great, and altho super-balloon tires have been encroaching on their field where the road or ground is not too difficult, yet caterpillars excell for use on rough and irregular ground of sand, muck or mud, with steep grades. They may be used under tractors, cranes, excavators, etc.

1.57. Walkers

are machines provided with a device on each side that acts together as legs and feet, tho both move simultaneusly, and the whole machine is advanst much as a man walks on crutches. Each leg is driven by suitable gearing, and to its lower end is attacht a hor member or foot whose lower surf is amply large to support the entire machine without sinking into soft ground. Normally, when digging (it is usually applied to drag-lines) the machine rests on its own base and the feet are raisd several feet from the ground. To "walk", the mechanism causes the lower ends of the feet to be thrust forward, then down against the ground until the base of the machine is lifted, and then, by a rearward thrust of the legs and feet, the machine is skidded forward. By repeating the steps, the machine may be advanst as desired. The direction of travel may be changed by merely rotating the machine, with its walking mechanism, on its base, as other cranes and shovels are rotated. As ordinarily mfd, "walkers" have booms 35′ to 175′ long, and can handle buckets up to 20 cu yds. Each "step" is about 7′, and walking speed about 18′/min.

1.58. Trolleys on Monorail

or overhead tracks are seldom practicable for engineering construction on account of the difficulty of constructing and shifting the tracks as the work progresses. They are used mostly in shops. The cableway, (sec 4) is usually far preferable for construction work. Trolleys are used on the hor jibs of cranes (sec 1.321) or on traveling cranes (sec 1.59), or on overhead tracks or monorail, or cableways. The trolley may be a mere car or truck carrying a hook hoist, propeld by pulling or pushing the hanging load, or the wheels may be geard for propulsion by pendant hand chains or other means, or by a motor on the trolley, operated either from the ground, from a distance, or from an operator's cage on the trolley. The trolley usually runs on four wheels bearing on the lower flanges of I-beams supported by their upper flanges. Such tracks may be provided with moveable sections acting as switches or turntables.

1.59. Traveling Cranes

In these, loads are handled from a trolley running on a "bridge", which in turn runs at rt angles on tracks on girders near the roof. They are usually permanent installations in shops, and not practicable for eng'g construction. But see sec 1.54.

1.591. Gantries or Bridge Cranes are similar to traveling cranes, except that the "bridge" is usually stay'y, or, if it is moveable, the colums or towers on which it is mounted run on tracks on the ground.

1.6. POWER MECHANISM AND POWER

1.61. Mechanism

For practically all of the hoisting and excavating machinery described in section 1.1 and its subdivisions (1.11, 1.12, etc), and also in 1.31 (derricks) and 1.32 (cranes), there is used or may be used one or another hoisting mechanism described in 2.22 and subdivisions, the number of gears or drums and lines depending upon what is to be controld, which may include hoisting (2 lines for "grabs"), "crowd", boom elevation, slewing, and movement over ground.

1.62. Power

The engin should be capable of exerting great force at starting, and at low speeds, especially where digging is involvd. The fuel should be cheap and such that it can readily be transported to the machine and stored, and it should not injure the engin. The engin should be of a type readily understood and operated.

1.621. Animals. A caution may be in order at least to consider the use of animals for certain purposes. Scrapers and light graders can be had especially designd to be pulled by **horses,** mules, etc. While the probable economy of horse *vs* mechanical power can be estimated for any given job, other considerations may enter, such as the availability of power machinery and men suitably skild in its use, as contrasted with that of horses and farmers or others (comparativly unskild with machinery) to handle them. See also pp 683-88 incl. **Elephants,** obtaind from circuses, sometimes available during the winter, have been used for miscellaneus handling of logs, poles or other objects, and even the pushing of vehicles as heavy as freight cars.

1.622. Electricity, where and when available, is especially good for the slow heavy starting pull, and has simple control. See also p 581 *t*, para 116.

1.623. Steam is especially good for the slow heavy starting pull, and has simple control, but the boiler's great weight is useful only as a counterweight, and the boiler may be troublesome on account of poor water, the fuel is cumbersome (even if oil is used), it is slower to start after shutting down, and is much less efficient than an internal combustion engin. By 1930 it had almost gone out of use except for locomotive cranes.

1.624. Gas (not gasoline) being generally not available, is seldom to be considerd.

1.625. Gasoline is still (1937) the most generally favord. Gears and clutches have been so developt that it can largely overcome slow heavy starting pulls. It is more efficient than steam, and the fuel is available almost anywhere.

1.6251. Gasoline-electric, in which a gasoline engin generates current for an electric motor or motors, has been resorted to and of course avoids many gears, and can exert great starting force, but it is not generally used. Initial cost, involving not only a gasoline engine and one or more electric motors, but also a dynamo, must be comparativly high.

1.626. Oil engins cost somewhat more than gasoline engins, but the operation is as simple and the fuel cheaper.

1.627. Diesel engins are being developt until they are now (1937) largely replacing gasoline engins. They are more capable than gasoline for slow heavy pulls. They cost about twice as much, but the fuel costs only about 25% as much as gasoline. The choice depends chiefly on whether the future use of the machine will effect suff saving to pay for the greater first cost and interest as compared with gasoline engins. They are more complicated and require special devices or engins for starting.

1.628. Comprest Air is largely used where it is available, as where rock-drilling is being done.

2.0. ELEVATING DEVICES

2.1. JACKS

Jacks are compact and readily portable devices capable of moving (especially lifting or lowering) heavy objects thru very short distances only, but can often be used for precise movements in very crampt places where other devices could not operate satisfactorily.

2.11. A Mechanical Jack, Figs 9, a, b and c, consists of a frame, *F*, which may be placed on the ground or other solid support, thru which slides a plunger, *G*, carrying a bearing plate, *B*, at its upper end, or a step (not shown) on one side, for supporting the load to be lifted, or for pushing laterally or otherwise. Between the frame and the plunger there is gearing which makes it possible to lift the load by means of a moderate force applied to the end of a lever. (Only the socket, *L*, into which the lever is fitted, is shown) In many cases this is merely a heavy **screw**-thread on the plunger, and the plunger is turnd by a stick or rod past thru holes in it, the top bearing plate being swiveld; or Fig 9a, the plunger, *G*, is turnd by means of a bevel gear turnd by a hor shaft with a square hole into which is fitted a square-ended rod (not shown) with a crank on the other end. Or, in the **rack-and-lever** jack, Fig 9b, the plunger carries a rack, *R*, which engages with gears or against which one or more pawls operate from a lever. Additional devices are provided either for reversing the action, so that the load may be lowerd step by step, or dropt at once. In some cases other kinds of gearing are employd, but these are the more usual The load can be held by the jack only at the stept levels determind by the ratchet—and not at any level as in the screw or hydraulic types.

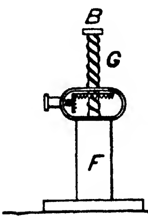

Fig. 9a
Screw
Jack

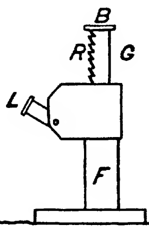

Fig. 9b
Rack-and-
Lever Jack

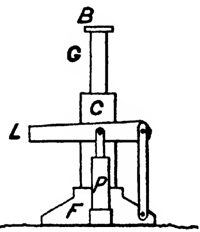

Fig. 9c
Hydraulic
Jack

2.12. A **Hydraulic** jack, Fig 9c, likewise consists of a frame or plunger, but the frame contains chambers filled with liquid. A lever actuates a pump, *P*, with a very small piston, which pumps the liquid from a storage chamber into a large cylinder, *C*, into which fits another piston carrying the plunger, *G*. Check and other valvs are provided for holding or lowering the load. Usually the pump is containd within the jack, tho sometimes it is separate and is connected with the jack proper by flexible metallic tubing.

2.13. Jacks on wheels are available for lifting one end or corner of a load, as an automobile, and moving it around on any smooth hard surface.

Commercial jacks may be obtaind in a great variety of sizes and capacities, from light one-ton capacity jacks for light autos, up to 50 and 75-ton cap for jacking up ry cars and locomotivs and structures generally. The ht may be anywhere from ½′ to 3′. The lift is usually a fraction of the ht, 1/3 to ½ or more, tho some, with double screws, have a lift as great as or greater than their own ht. For greater lifts, the load, when raisd as far as possible, must be blockt up, and the jack then shifted so as to raise the load again, and so on. Wts of jacks may be from abt 10 lbs to 400 lbs or more. Small trucks may be had for transporting heavy jacks.

2.15. Pneumatic or other power may be applied to some types of jacks.

2.16. Melting Ice Cakes were used to lower telefone conduit abt 3′ in 500′ sections weighing 60 tons. Every 6′ the earth under the conduit was removed and replaced by blocks of ice 21″ × 22″ × 11″. The remaining earth was then excavated gradually as the ice melted. The conduit sank abt 1/3″/hr with air temp around 55°. The operation was very satisfactory. (Construction Methods, 1935. July). Melting ice has been used in other cases.

2.17. Sand Jacks are sometimes used for the lowering of heavy loads such as arch centers, plate girders, etc, and may obviate much cribbing and shifting of mech'l jacks.

In lowering a 1000 ton drawbridge over the Passaic R at Newark, N J, dry sand was confined in a box open at the top, 4′ wide, 52′ long, abt 11′ high, built of 12″ × 12″ timbers. Four plungers fitted into the box with ½″ clearance, and settled without jerking, on releas of sand thru 2″ holes in the bottom. Pressure on sand, 2,815 lbs/sq in. Sand would not flow from holes in side.

In lowering two 142′ girders, wt 121 tons each, at Glenview, Ill, (Eng News-Rec, '36 Oct.8), the boxes were 3′ wide, 11′ long, 12′3″ high, of timbers 8″ × 16″. Heavy timbers rested on the sand, coverd by a bearing plate on which rested the girders. Lowering was accomplisht by men standing on top of the jacks, removing the sand with small shovels.

Sand jacks used in Switzerland (Eng News, '11 Jan 5) were metal cyls, diam 26.8″, ht 39.4″. Metal piston, fitting closely, was 31½″ high. Total lowering, 24″. Load 282 tons, or 1000 lbs/sq in on dry quartz sand from sand-blast work. Hole in bottom 2½″ diam. Sand flowd slowly and uniformly. Operation very satisfactory. A sheet of lead draped over top of jack acted as a hood to prevent entrance of water.

2.2. HOISTS

There is much ambiguity regarding the word "hoist", for the name is applied, usually without any qualifying word to distinguish, to (1) hoisting devices which hang from a support above, as described in sec 2.21, and (2) hoisting devices resting on the ground or other foundation, as in sec 2.22. To distinguish betw the two, we call the first "Hanging Hoists", the smaller sizes of which especially are called "Winches"; and the second "Drum Hoists". Hoists, unless mounted on trolleys, booms, or otherwise, move the load only vert'y.

2.21. A Hanging Hoist

consists of a frame, usually with a hook or other means at the top for attaching it to an overhead support, containing an assemblage of gears or other means for applying power, and a hook or other grabbing device hanging from the gears or sheavs, for attaching the load. It may be of use for light loads, where high efficiency and high speeds are not required.

2.211. A Hand Hoist is operated by a "hand chain" which hangs in a loop below the gearing. Pulling down on one side of the loop, the load is hoisted; pulling on the other side, the load is lowerd; while provision is made for holding the load in position when there is no pull either way on the hand-chain loop. The gearing may be either a worm gear, a train of one or more spur gears, a planetary gear, a differential gear, or any one of several other special types. The **worm gear** or **screw hoist**, can handle loads but slowly, tho a heavy load requires a comparativly easy pull on the hand-chain; while it requires no brake to hold the load in position. Owing to the friction of the worm, its efficiency is low, around 40%. Capacity from 500 lbs to 6000 lbs or more. **Spur** gears require special additional mechanism for holding the load when it is not being operated, but their efficiency is high, around 80% to 90%, and the ratio of load to pull may be almost anything, depending upon the number of gears in the train. In the **differential** hoist, only one chain is used for both hand and load. The chain is continuous and hangs in two loops, one loop hanging free for pulling by hand, and one under a sheav to which the hoisting hook is attacht. The two upper loops pass over a sheav having two groovs, one a little larger than the other. Thus, the larger sheav hauls up its length of chain a little faster than the smaller one lets down its length of chain; and these two lengths, passing under the hoisting sheav, thus move the load much more slowly than the chain itself moves. Lowering is accomplisht by reversing the motion. Owing to internal friction, this hoist requires no brake, but its eff'y runs from 28% to 38%. Cap, 500 lbs to 6000 lbs or more.

2.212. An **Air or Pneumatic Hoist.** The simplest of these is a mere **cylinder,** containing a piston or rod, to which is attacht a hook or other device for attaching the load. It may be operated by varius combinations of air pressure, as (1) pressure only below the piston, (2) variable pressures below and above, or (3) full air pressure below and variable above. (2) or (3) give better control than (1) by tending to prevent sticking of the piston. There may be in addition an oil control which affords even more definit movement. Cylinder hoists have the advantage of quick movement, but the amount of movement is limited by the length of the piston, the stroke being from 4′ to 8′. These may be had with cyls from 2″ to 24″ diam, operated by pressures from 60 to 100 lbs/sq in, with lifting capacities from 175 lbs to 40,000

lbs, using from 1 to 100 cu ft of free air for a 1' lift For greater movements, **air-motor** hoists may be used. These are two- or three-cyl air motors, usually employing oscillating or rotating cyls, with a max lift of 20', and capacities from 1,000 lbs to 10,000 lbs.

2.213. Electric Hoists, tho generally heavier than air-hoists, are very serviceable, where 110 to 550 volt, D C or A C is available. Motor, gearing and hoisting drum are all mounted together compactly. Control may be had from the floor by means of pendant cords, or, especially where the hoist is mounted as a trolley running on overhead track, (see sec 1.58) the operator may ride with the hoist, with or without a cab; or by "remote control" from a convenient point away from the hoist They are of course supplied with one device or another, usually automatic, for holding the load when it is not being operated. Capacities run from 500 lbs to 40,000 lbs, with lifts from 30' to 10', respectivly.

2.22. Winches and Drum Hoists

are usually mounted on the ground or engine- or crane-platform.

2.221. Hand Winches or Crabs. The simplest form of winch consists of a crank or cranks turning an axle, geard to turn a drum on which a rope is wound, all being held in place by a wooden or metal frame. Capacities, up to 1½ to 2½ tons. To hold the hoisted load, either a worm gear is used, or (with spur gearing) a pawl or brake is provided, the brake permitting lowering under good control. All winches and drum hoists are elaborations of this A double drum may be provided with special gearing for handling two lines. In a "double-purchase" winch, gearings are provided whereby either of two drum speeds may be obtaind from a given crank speed, with inverse changes in pulling force.

2.222. Horse Winches may be useful where power is seldom req'd. By means of bevel gearing, a vert shaft is provided, to which is attacht a long lever to which is hitcht a horse that walks around the winch. Provision must be made to lead the hoisting rope either well above or below the horse.

2.223. Power Hoists or **Power Winches** may be operated by any kind of power mentioned in 1.622, *et seq.* They are usually equipt up to 50 to 100 HP, tho occasionally as much as 300 to 400 HP or more for special hoisting and conveying. For excavating machinery, there are usually three drums. See sec 1 61. These drums usually receive their power thru appropriate gears and clutches, altho in electric excavators there is sometimes one motor for each drum, thus reducing gearing but increasing cost for motors. "The modern standard heavy duty hoist would include wide, capacius drums, brakes mounted on flanges opposit the fric flanges, and compact lever arrangement so that even three-drum and swinging gear hoists are operated from one position.......The entire outfit with levers at the side; hand friction, foot brake, or extension levers bankt in a rack located at the point of greatest operating convenience." (F D Hooper, Eng News-Rec, '30, Apr 3). Many of the heavier machines are now (1936) provided with electric, pneumatic or hydraulic control, greatly reducing the labor of the operator.

---

*Materia' Handling Cyclopedia, Simmons-Boardman Pub Co.

2.224. Capstans (almost invariably power-operated) may be of servis for occasional pulling, as for short hauls of cars or ships, or assistance to trucks. The (hemp) rope is not fastend to the drum, but is merely wrapt around it three or four times, which makes it possible to apply a very strong pull to the object to be moved, by the strength of one man holding back on the free end and taking up the slack as it is wound in. The drum or **niggerhead** is conceaved to keep the rope from working its way off the end or jamming against the end flange. *Lowering* by this means is awkward and dangerus unless the capstan is reversible.

2.23. Material Hoist Towers or Elevators

are of great servis in building construction for lifting mat'ls to different floors, and for returning barrows, etc. The best location is usually 6 or 8 ft outside the building wall, and opp a vert row of windows, altho they are often placed within the building.

A mat'l hoist consists of a crude elevator with only a platform and side frame-work, to the top of which is attacht a hoistin rope. It runs in gides inside a rectangular tower, often of timber, of temporary construction, but also frequently of steel of stock mfr with bolted connections, which may be used repeatedly in different locations. The cable passes over a sheav or sheavs at the top of the tower, and thence to a drum-hoist (sec 2.223).

For ordinary loads, the tower uprights may be of 4″ × 4″ timbers if only a few stories high, and 6″ × 6″ or more if over 100′. For heavy loads, and especially where the lowering speeds are high and the retardation likely to be severe, the tower should be carefully designd, and the cable stresses well taken care of. The towers should be braced to the building at intervals or maintaind upright by frequent guys, and completely braced by diagonals to resist hor thrusts due to wind or irregularity of track, and to aid in its action as a colum, the bents being abt 6 or 7 ft high, or approx'y square. The size of the elevator platform will be governd by the mat'ls to be hoisted, or by the barrows and trucks loaded on it, say 6 or 7 ft square.

Danger in the operation of such a hoist is great. Excessiv speeds and sudden stops may shake the load out of place on the platform, and create very high stresses thruout the tower. The operator must be thoroly competent and careful, and there should be such safety devices as automatic gates and interlocking signals, as may be req'd by law. In interior instalations these may be as elaborate as for permanent passenger elevators, especially if men are to ride on the hoist platform.

2.24. Vertical Conveyors

of the bucket type, see sec 5.2.

2.25. Inclined Hoists

Where material is to be hoisted up a slope, a drum hoist may wind a cable to the lower end of which is attacht a car running on a track, as is prevailing practis in mines having a steeply inclined passage for haulage. There seems to be no standard design for such a rig, and it may often be improvised from idle equipment on hand. In mine work, there are often two cars running on two tracks (possibly using a gauntlet) thus doubling capacity and avoiding waste of power req'd to hoist one unbalanst car. The inclination of the cable requires the use of sheavs or rollers all along the slope, spaced suff'y close to keep the cable from dragging on the ground or ties.

Assistance to Trucks on heavy grades may be given by a winch or drum hoist, a cable from the drum being hookt to each truck to be handled on the grade which may be as high as 35% or 19°, without danger due to slippery surface. This may be useful in removing mat'l from a building excavation. It is an old device formerly used to assist horses with wagons or men with wheelbarrows up grades entirely too steep for them alone.

3.0. TROLLEYS, TRAVELERS

See section 1.58.

4.0. CABLEWAYS

Where there is need to transport mat'l further than can be done by "throwing the bucket" of a crane, the crane may still be used by stringing a stationary or **"standing cable"** or **"track-cable"** from the end of its boom to some distant anchorage. On this cable run the wheels of **a trolley** or **carriage,** much as a car runs on a track, tho the load hangs below. This is largely used for operating scrapers.

4.01. From this a great variety of forms has been developt; only the more usual ones being described below. There are **two main types,** (1), secs 4.1 and 4.2, that in which the supporting cable is stationary, and the load is carried by a carriage running on wheels on the cable, and is propeld by a second moving cable, and (2), sec 4.3, that in which the supporting cable moves continuusly, and to which the carriages are attacht. **Nomenclature** has become very vague and varied, and altho we mention the more customary names, we shall in general use those names which are the more naturally descriptiv.

4.02. Utility. For utilities of special types, see "Utility" under each type described below. In general, cableways are often valuable for the excavating, transporting and depositing of earth, coal, ore, concrete, or other mat'ls. Except where moveable towers are used, irregular topografy is no obstacle, it being perfectly practicable to cross deep valleys, canons, marshes, swamps or bodies of water (see Dredging, p 581c, para 28); and for handling mat'ls as timber, steel, concrete, etc, in building bridges, dams and other long structures. There need be no interference with highways, RRs, or water traffic. For moderate dists and loads, espec'y where a constant delivery of mat'ls is req'd over very rough country, the cableway compares very favorably with a RR and usually has many advantages over it. It requires a min rt of way (towers being placed on property lines where possible), and much less mat'l for "track", no earthwork, and no bridges (being itself a kind of suspension bridge of max simplicity*). Usually hor curvature can be avoided. Weather has practically no effect on transportation.

---

* For example, a single-span cableway may be elaborated into a suspension bridge, carrying track and dump trains out on it for constructing an earth fill.

4.1. Tower Cableways

In Fig 10 the span is shown very much shorter than it usually would be. To enlarge the range of the rig outlined above (in 4.0), the crane or hoisting engin, *E*, may be built into a tower called the **"main tower"**, *M*, and the track cable, *C*, stretcht from it to a **"tail tower"**, *T*, which is usually much smaller, so as to give a grade to the cable, so that the carriage may run in one direction by gravity. Then, for transporting, only one **traction cable** is needed from the engin to the carriage. But where suff grade cannot be obtaind, the traction cable must consist not only of this **"inhaul"** cable, *I*, but also of an **"outhaul"** cable, *O*; thus forming a loop of cable betw the two towers, with the carriage, *K*, cut into the loop. This, too, is largely used for handling scrapers, when the inhaul cable may be called the **"drag-line"** and the outhaul cable the **"back-haul line"**.

4.11. Hoisting and lowering the load is sometimes accomplisht by pulling up or slacking off on the standing cable; and the device is then known as a **"slack-line cableway"**. But more usually, another line, called a **"hoisting line"**, *H*, is provided from the crane to the carriage, thru which it runs over a sheav down to the load (and usually under another sheav and back up again to the carriage).

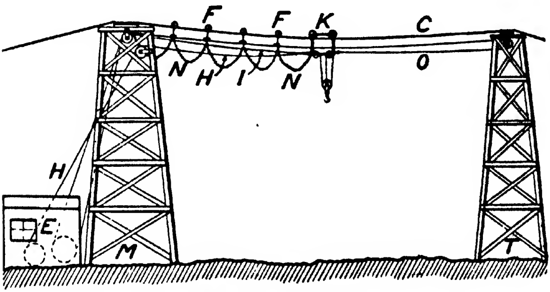

Fig. 10. Cableway

4.12. Where the grade is sufficient, and the load is to be taken on or dropt off at one point for some time, one cable may serv as a **combined traction and hoisting line**, by attaching a block to the standing cable, to stop the carriage over the required point. The block may be shifted from time to time as required. However, the use of separate cables affords a more flexible tho more expensiv installation.

4.13. Rope- or Cable-trolleys or Fall-rope Carriers, *F*, are often employd to support one or more of the cables and to prevent the several ropes from fouling each other. Each consists of a light frame, with a wheel at its top, which may run on the standing cable, and thru which slide the other ropes or cables. Sometimes they run on an additional line of their own, called a **"trolley rope"** or **"button rope,"** carrying stop-buttons of graded sizes for spacing the trolleys, of which there may be a string of 6 or more. In some cases they are connected with each other by chains, *N*, which sag between them, so that they tend to space themselvs equally.

The equipment described above (4.1 etc) can serv only a very narrow area, limited in width by the extent to which the hanging load may be deflected by one means or another.

4.14. To Serve a Small Area, varius devices are used. For coal piles and similar limited areas, the towers are sometimes mounted so as to **oscillate on rockers,** so that they may be tilted at right angles to the cables, thus serving an area perhaps 25′ or 50′ wide.

4.15. For Larger Areas the towers may be mounted either on wheels running on tracks at rt angles to the cables, or on caterpillars. The "width" and "length" of the area servd may then become interchanged, the cables stretching across the *width*, and the towers moving paralel with each other along the *length*. Where **tracks** are used and the area is great, it becomes economical to use a limited length of track and shift it as progress is made, either by hand or by small crane. Where **caterpillars**, sec 1.56, are used, and the installation is heavy and the ground soft, it may be necessary to provide corduroy roadways, and these then must be shifted. **Radial cableways** serv a sector, the tail tower being arranged to travers a portion of a circle on a permanent track.

4.17. Utility. See also sec 4.02 When the towers are fixt in position, they may serv only a very narrow area. When the ground is fairly level, and there is a large area to be servd, moveable cableway towers are coming into extensiv use, especially on the Mississippi R; but the equipment is too costly to be profitable where only a comparativly small area is to be servd.

4.18. Dimensions. Head tower hts range from 75′ or less to 125′ or more; **tail towers,** 25′ to 50′. **Spans** of a few hundred ft may be used for scraper outfits having no towers. With towers, spans of 1000′ to 1500′ are not unusual, a span of 2295′ having been used on the Hetch Hetchy project (Eng News-Rec, '29 May 16, p 793); and another of 2700′, carrying 20 tons, using four 2″ cables (Eng & Contr, '29 Sep, p 358). **Standing cable** diams should be computed from span, sag and load, but run from 1″ to 3″. **Other ropes** for traction, hoisting, etc, are usually about 1″ diam or less. Their size should be kept as small as consistent with hauling stress, to minimize wear over sheavs.

4.19. Capacities. Where **buckets** are used, their capacities may be from 5 to 10 cu yds or more. **Loads** of 15 tons are quite practicable. A cableway of 1200′ span at the Hoover (Boulder) dam could handle 150 tons (Eng News-Rec, '32 Oct 6, p 408). Traction **cable speeds** of 300 to 500 ft/min (3½ to 5½ mi/hr) are usual, tho some have run as high as 1500′/min. On levee work, tower excavators have handled from 150,000 to 200,000 cu yds per mo, during season.

4.2. Aerial or Cable Tramways

(with stationary supporting cable), are the next development where it is desired to transport mat'ls over greater dists than can be negotiated by one span. In this type, the standing cable is supported on intermediate towers as well as by the end towers, placed at suitable intervals of several hundred ft to around 3000′. In order to increas the capacity of the installation, a number of carriages or carriers is used, each running on the standing cable, and attacht either permanently or by means of grips to the traction cable. **Loading and unloading** may be accomplisht by any one of a number of devices too numerus to detail here. In some cases the carriers are attacht or detacht from the traction cable, and run off from, or on to the standing cable.

in others, each carrier remains permanently attacht to the traction cable, and is servd as it passes loading stations by an auxiliary carrier, which runs along in paralel a dist sufficient to load or unload, and which then backs up to serv the next carrier, being itself loaded or unloaded by any one of a number of means.

4.21. Such cable tramways must nec'y be **"double-track"**, having two standing cables, usually 6′ to 10′ apart, with a complete loop of traction cable, for the return of the carriers, and the ends of the standing cables must lead to and from mono-rails which gide the carriers around a half circle back to the other standing cable for the return trip. By such mechanism, hor angles in the alignment may be establisht, tho the speed should then not be over 400 or 500 ft/min*.

4.25. Utility is much the same as described in secs 4.02 and 4.1 relating to fixt towers, except that loading and unloading can take place only at *points* along the *line*, and *no area* whatever can be served. But *lengths* of five miles are entirely practicable, and there are many installations over 10 miles long, and up to 15 and more. When the length of a traction line is so great as to be cumbersome, other sections of traction line may be added almost indefinitly, the carriers being automatically detacht at the end of one traction section, then coasting a short dist on a monorail to the next section where it is transported by the next traction cable, each cable being driven by a separate motor. Grades up to 20 and 40% are usual, and 85% has been attaind, and a moderate amt of curvature is quite practicable.

4.26. Capacities in tons per hour are *independent of length* of cableway, but are approx proportional to speed of traction cable, number of carriers on the line, and the capacity of each carrier. **Speeds** range from 300 to 600′/min; the **spacing** of carriers from 150′ to 500′; and the **capacity of carriers** from 5 to 40 cu ft, or 600 lbs to 3500 lbs; and the resulting **load per hour** from abt 5 or 10 tons to as much as 250 or 200 tons.

4.27. Horse-Power required depends on diff of elevation, loads and speed, but is usually light compared with a RR, ranging from 5 or 10 to 100, and averaging around 50.

4.28. Crews required are comparativly small; 3 or 4 men for small installations, up to 10 or more for larger ones.

4.3. Moving or "Single" Ropeway

"Single" refers to a cableway in which *one* cable moves, and does both the carrying and the hauling. Like cable tramways, sec 4.21, they are "double-track", *not* "single". Their use is common in Europe, and rather rare in the U S. They are simpler, and cheaper to *instal* but they call for an exceptional rope, for as the size is increast to support the load, the bending stresses over the sheavs become serius, and such ropes wear out quickly, increasing *maintenance* costs. Hor angles are hardly practicable. There is increast difficulty keeping the line taut, and in designing clips to attach the carriers to the rope so that there will be no interference with the carrying sheavs, and this precludes the use of grades much over 30%. Economic **capacities** run from 50 to 100 tons/hr*, each carrier taking from 100 lbs to 800 lbs or more*. **Speeds** up to 450′/min.*

---

* Aerial Tramways, by F C Carstarphen, A S C E paper No 1675.

5.0. CONVEYORS

In this section we treat only of "*continuus* conveyors" which deliver material continuusly, or practically so; and do not include cranes, hoists, cableways and vehicles, which are intermittent in their action.

Utility. The conveyors most useful to the C E are the belt and bucket conveyors. Their fields of application overlap somewhat, **belt conveyors** being of max use for hor or nearly hor movements, since mat'ls cannot be handled by them on very steep grades. **Bucket conveyors** also can carry mat'ls hor'y, but their chief usefulness lies in vert movements or those too steep for belt conveyors, or where it is desirable to transport, by the same machine, vert'y as well as hor'y. It is not possible to have hor angles in the line of movement of either type. See also under "Utility" under each type treated below in sections 5.1, 5.2, etc.

5.1. BELT CONVEYORS

See also "Belt Conveyors and Belt Elevators" by Frederick Hetzel, publisht by John Wiley & Sons, New York, N Y.

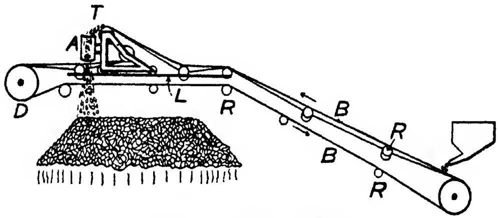

Fig. 11. Belt Conveyor

5.11. Construction

A belt conveyor, Fig 11, consists primarily of a continuus belt, *B*, hor or somewhat inclined, the two halves traveling in opp directions over rollers, *R*, or idlers spaced closely enough to prevent troublesome sag of the belt betw them, and driven by power applied to a drum, *D*, around which the belt passes at one end. The upper half of the belt carries the mat'l to be transported, and the lower half returns empty. The illustration shows a very much shorter conveyor than usual.

5.111. The **Belt,** *B*, is usually of cotton or canvas fabric, coated with rubber, the two being in different proportions according to the servis req'd. Plain cotton belts are of use only in dry locations and for light work. The function of the fabric is to prevent stretching, and that of the rubber to protect the fabric from dampness, chemicals, gases, abrasion, etc. Belts are not as durable as buckets, but generally much cheaper. They are made in varius thicknesses up to 10-ply, and in widths (varying by 2″) from 12″ to 60″, the more usual being 24″ and 36″, and are used in conveyors up to 1000′ in **length** (the belt being double that, counting the return half) altho the usual limit of conveyor length is more like 800′ or less, two or more belt conveyors being used in tandem where greater dists are to be coverd, the first delivering to the second, and so on.

5.112. Idlers or Rollers, *R*, used to support the belt, are usually of metal, cylindrical under the returning belt, but under the upper or delivery half, they may be concaved somewhat, (now practically obsolete) so that the belt forms a trough to prevent the mat'l from being shaken off. The ends of the idlers, being of larger diam than the center, travel faster, and cause rubbing against the belt, which hastens wear. To overcome this, the idlers are usually made up of from 3 to 5 or 6 short rollers, the central ones being hor, and the end ones being tilted 20° to 45° from the hor'l, so as to form the desired trough in the belt. The **bearings** of the idlers are very important, especially if abrasiv mat'ls are handled. They are preferably ball- or roller-bearing, self-oiling, and carefully designd to exclude mat'l falling from the belt. An idler which fails to rotate, causes rapid wear of the belt and of itself, wastes power.

5.113. Drive. It seems best to have the driving drum, *D*, at the unloading end, for then the max pull need not be transmitted thru the returning belt. It may be faced with rubber to minimize the pull nec'y to maintain suff friction. The tension may be controld by screw **take-ups** adjusted by hand from time to time, which may be suff for comparativly short machines. For long ones, a sliding take-up which maintains constant tension by means of a weight, seems preferable.

5.114. Loading. The belt may be quickly damaged by violent loading. The mat'l should be deliverd to it in its direction of movement, in small pieces and with min drop, and a steel plate under the belt at that point may be of help if heavy chunks are likely to be deliverd to it.

5.115. Unloading. No special device is needed for unloading, if it is to take place at the end of the run, the mat'l merely falling off as the belt curvs around the driving drum. However, **trippers,** *T*, are of great value where it is desired to distribute the mat'l over a long line. The tripper is a car running on rails, *L*, lengthwise of the conveyor, with two principal idlers or rollers, over which the delivery belt is drawn down and back under and then bent forward so as to resume its course. The mat'l falling off the belt passing over the first roller is caught by an inclined apron or trough, *A*, at rt angles to the belt and is thereby deliverd to one side of the conveyor. One of the rollers is geard to the wheels of the tripper, so that the tripper is causd to move slowly longitudinally, thus delivering the mat'l along the side of the conveyor as far as the tripper is arranged to run. At the end of each run, it encounters a stopping device, not shown, which causes it to reverse and return. A **Discharge Sweep,** consisting of a scraper placed diag'y over the belt, may be used in place of the tripper to unload mat'l before it reaches the end, but its position must be continually changed by hand unless the unloaded mat'l can be tolerated in piles instead of being evenly distributed.

5.116. Mounting. The idlers must of course be mounted on something constituting a frame. Often a metal truss is provided; sometimes, if the installation is fairly permanent, wooden stringers on posts or piles are used.

5.117. Stackers. To cover an *area*, the truss or frame becomes a boom, and is either pivoted at the lower or loading end, while the delivery end is arranged to swing hor'y (as well as being adjustable vert'y), or it is mounted on crawlers or tracks. An example of this was used on the intake canal of the Beauharnois power project, Quebec, in which a

36″ belt conveyor was carried on a truss boom 106′ long, pivoted from the base of a gantry 40′ long, running on track of 32.5′ gage, for the placing of rip-rap with a max size of 14″. (Eng-News Rec, '32 Sep 8). Booms range betw 50′ and 135′ in length. Smaller stackers designd primarily for mobility, are known as Portable Loaders, see sec 5.3.

5.118. "Elephant Trunk" Spouts, fed by funnels under the delivery ends of conveyors, made of flexible canvas or similar mat'l, are often convenient for the placing of concrete within a limited area without moving the entire machine.

5.12. Operation

The **speed** at which the belt is operated is usually betw 300 and 600′/min. Belt **running out of line** may be partially corrected by reducing the troughing, and also by setting the idlers a few degrees off from a rt angle with the belt. Other remedies are objectionable. (Hetzel, Belt Conveyors).

Lubrication of idlers is important, and if not self-lubricating, regular times should be establisht for lubrication

Remote Control may be employd where two or more conveyors are used in tandem, delivering from one to the next, preferably interlockt if there are many conveyors, so that no one conveyor will deliver to another which may not be running.

5.13. Capacity and HP

The following table is computed and averaged from figures given by Link Belt Co, Materials Handling Cyclopedia, and Marks's Mech Engr's Hand-Book, assuming speed of belt as 500′/min and wt of mat'l 50 lbs cu ft

Width of belt, inches	12	24	36	48
Capacity, cu yds/hr	85	340	790	1400
" tons/hr	115	465	1050	1850
HP per 100′, level	2.0*	8.4*	15.7*	25.5

If mat'l is raised, add'l HP is tons/hr × ht lifted in ft ÷ 1000.

5.14. Utility

Belt conveyors are of use chiefly for transporting granular mat'l hor'y or up moderate **grades**, 15° to 20°. This may be increast somewhat by adding cleats to the belt. In one case, aggregate was reported as carried up a 32° grade. The **materials** may be coal, coke, sand, gravel, ore, earth, cement (bulk or bags), concrete, and other mat'ls, such as grains, usually handled in fixt installations in bldgs. Hot or wet ashes will injure the belt. With concrete and other somewhat adhesiv mat'ls, it may be nec'y to employ scrapers or "discharge sweeps" placed diag'y over the surface of the belt at the discharge point

Outfits for handling **packages** are similar to those for granular mat'ls, with a few differences, but are usually permanent installations in bldgs.

5.15. Examples

In delivering concrete for the construction of a sewage treatment plant at Ward's Island, New York, four 24″ rubber belt conveyors were used, aggregating 1865′, three of them with trippers arranged to deliver conc at any pt thruout their length. (Eng News-Rec, '32 Nov 3).

In the construction of the Merchandise Mart in Chicago, 44 portable conveyors were employd, using cleated belts with effectiv lengths of 40′ to 60′, running 250′/min, each delivering abt 1 cu yd of conc per min. (Eng News-Rec, '29 Sep 12).

* F V Hetzel's "Belt Conveyors and Belt Elevators" gives HP as about half these values.

In the construction of the 100′ × 2200′ roof of a subway in St Louis, Mo, 8 portable belt conveyors were used, 26′ c to c, totaling over 200′, having 24″ belts run at 150′/min, handling abt 30 cu ft/min at angles up to 20°. 14 men in attendance. (Eng-Contr, '31 Aug).

5.2. BUCKET CONVEYORS

5.21. Construction

In the bucket conveyor, buckets are arranged in a continuus series, mounted on one or two chains, or on a belt. If the run is vert and short, they move without any gides, but if inclined, the part that is rising travels on gides or rails, and the part that is descending may hang freely, altho long runs of a story or more in ht usually need to be gided, both up and down, as they may get to swaying badly. Much or most of the run may be hor, when tracks are provided for both directions. The chains pass over sprockets at each end, and wherever there may be changes in direction.

5.211. The **Buckets** are usually malleable iron castings, or made up of sheet metal; usually V-shaped as seen from the side, with the upper end of the V open and up during carrying movements. They range in size from much less than 100 cu ins contents to 1000 or more, the open ends having areas from less than 25 sq ins to 100 or more.

5.212. **Chains.** Usually there is one linkt chain on each side of the row of buckets, and the buckets are attacht to them, as are also the **rollers** or **flanged wheels** which run on the gides or rails. The joints are the critical parts of the chain because of wear, and should be well designd and of hardend mat'l, with good provisions for oiling.

5.213. **Drive.** The chains of buckets may be driven by power applied to one of the sprockets at the end of the run.

5.214. **Loading** is accomplisht by throwing the mat'l to be transported into a pile or into a trough, "boot" or "hopper", or pit at the lower end of the run, the buckets digging into the mat'l and lifting it as it accumulates.

5.215. **Unloading** is accomplisht in either of two ways. (1) In the **"centrifugal"** method, speed is maintained suff to throw the mat'l from each bucket at the top of the run far enough out to prevent it from falling back onto any part of the conveyor, the mat'l being caught in an apron or trough, or falling directly onto the stock pile or embankment or other place where it may be wanted. (2) In the **"perfect"** or **"positiv"** discharge, the buckets are pivoted to the chains, and a tripping device, set at the place for unloading, causes them to tilt and drop their loads at that point. These trippers may be shifted to change the point of discharge as desired.

5.22. Operation

The **speed** of the chain of buckets is from 150 to 400′/min for "centrifugal" unloading, and from 75 to 150′/min for the "perfect" or "positiv" discharge, the speed of the latter being kept low on account of the impact of the tripper.

5.23. Capacity and HP

Authorities disagree so widely on these figures that it seems useless to say more than that on account of the lower speed and greater wt of moving parts, the capacities of bucket conveyors, are generally markedly less and the HPs higher per ton/hr, than those of belt conveyors.

5.24. Utility

Being a much more cumbersome machine than the belt conveyor, installations are seldom more than a few hundred ft long, and the rise is limited to about 150′. However, it is only where the grade is less than 15° or 20° that the belt conveyor can be used in place of the buckets, which are well adapted to handling coal, ashes, cement and water, and are largely used for such work in permanent installations. But see below, 5.3, Portable Loaders.

5.3. PORTABLE LOADERS OR CONVEYORS

5.30. Fig. 12. These units are simply self-containd continuus conveyors, belt or bucket type, of comparativly small dimensions, with sufficient lift to load mat'ls into trucks, *T*, and mounted so as to be moved readily from place to place, and so as to be fed against a pile of mat'l, *E*.

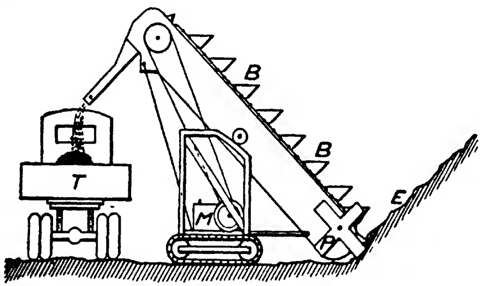

Fig. 12. Portable Loader

5.31. Construction

does not differ greatly from that of the conveyors described in secs 5.1 and 5.2.

5.313. The **Drive** is part of the machine and takes its power from the motor, *M*, provided.

5.314. Loading is accomplisht with the **belt** machines by loading onto the belt at its lower end, by shoveling or from hoppers, or from another belt or bucket conveyor. The buckets, *B*, of **bucket** conveyors, Fig 12, can receiv mat'l in the same ways, but have the advantage that the faces of the buckets can be gradually advanst against a pile of mat'l, *E*, or even against light earth in place. To gather together the sides of the pile, and not merely dig a channel thru it, **"paddles"**, *P*, are frequently provided at the two sides of the foot of the conveyor, on a shaft at rt angles to it, of propeller type, or as a ribbon in the form of a helix. Sometimes they carry cutting tools of varius kinds to assist in breaking up fairly hard mat'l.

5.315. Unloading is similar to that of larger conveyors, but always at the upper end only.

5.316. Mounting. Where **belt** conveyors are to be used in the same place for considerable periods of time, they are often mounted on a pair of wheels with wide treds. The **bucket** conveyors, however, are now (1937) almost always mounted on crawlers or caterpillars, which makes it possible not only to move them readily from job to job or from place to place, but also to feed the machine against the pile of mat'l to be handled.

5.32. Operation

The **Speed** of the **belts** in portable conveyors is from 150 to 250'/min, and of **buckets** from 100 to 135'/min.

The entire unit can usually be handled by one man, tho other men may be req'd to keep it properly fed.

5.33. Capacity

of portable **belt** conveyors may be from 10 to 50 cu ft/min, while portable **bucket** conveyors may handle from 20 to 80 cu ft/min. **Horse-power** required for **bucket** machines, from 2 to 20 and more; for **belts** somewhat less. The belt conveyors for loading trucks are at a disadvantage because the low angle necessitates a greater length and cumbersomeness to obtain the req'd height. The **weights** of belt machines run from 2000 lbs to 8000 lbs, and of bucket machines from 1000 lbs to 6000 lbs.

5.34. Utility

is much the same as for larger conveyors as regards mat'l handled. Recehtly wet concrete has been handled very successfully. As with the larger machines, the angle of the belt conveyor is limited to about 20°. Both belt and bucket portable conveyors have proven very useful on account of their mobility, and are very largely used in construction work.

5.4. APRON OR PAN CONVEYORS

5.41. Construction. Instead of a series of buckets, there is a series of steel plates 18" to 72" wide, carried by chains, and arranged so as to overlap while carrying, forming an almost continuus surface. The surface or apron thus formd often moves betw longitudinal stationary vert plates along each side, to increas capacity.

Loading is done much as in other conveyors, care being taken that large chunks do not fall heavily on the plates.

Unloading, on account of the ridges and side plates, can be done only at the end of the carry.

5.42. Operation Speeds range from 50 to 75'/min or more, tho sometimes very low speeds are used, as where coal is to be fed at a low rate for boilers.

5.43. Capacity ranges from 40 to 400 or 500 tons/hr for mat'ls of 50 lbs/cu ft, depending chiefly upon the width of the apron.

5.44. Utility is limited to mat'l not so finely divided that it may fall thru the joints betw the plates as they pass over sprockets, or betw the plates and the vert side pieces; nor must the mat'l be adhesiv. By providing a transvers ridge at the edge of each plate, mat'l may be carried up grades as high as 30°.

5.5. SCRAPER OR FLIGHT CONVEYORS

are similar in **construction** to the bucket and apron conveyors, except that the mat'l is pusht along by **"flights", scrapers** or **pushers,** spaced from 1½′ to 3′, which are merely vert plates of wood or steel, attacht to and pulled by a chain, that fit loosely into a **trough.** The flights may be either in contact with the trough or may be suspended slightly to reduce friction. The chain and flights run on gides or tracks suitably mounted. **Unloading** may be accomplisht at any point along the trough by providing a gate or trap-door in the trough, or at the end. They are built in **lengths** up to several hundred ft. The **speed** of the chain is usually around 100 or 150′/min. **Capacity,** approx number of tons per hour = two-thirds the area of a flight in sq inches. The **utility** is limited chiefly to non-abrasiv mat'ls such as coal and ashes at grades not over 45°.

5.6. SCREW, HELICOIDAL, OR "SPIRAL" CONVEYORS

Such a conveyor consists of a hor or inclined shaft, fixt in position, to which is attacht a metal helicoidal blade, all forced to revolv in a trough of the same **length,** 8′ to 12′ long. **Loading** is done by throwing the mat'l around the lower or intake end of the screw. **Unloading** may be done as in flight conveyors. **Capacities** as follows,—

Diam of screw, inches	7	9	12	16
Approx speed, rev/min..........	110	100	90	80
Cement, bbls/hr..................	57	132	300	670
Coal, tons/hr..................	6½	16	36½	80
Sand, cu ft/hr	180	420	930	2000
Approx HP req'd for sand.	2¼	5½	12½	25½

Utility. In addition to handling grains and the like, the screw conveyor can handle cement, coal, sand, gravel and ashes, provided lumps are not over 1″ across, on grades up to 15° to 20°. The handling of sticky mat'ls may be facilitated by the use of a helicoidal metal ribbon providing an open space near the shaft, while a great variety of forms of paddles, propellers, or ribbons, are used for **mixing** several mat'ls, while transporting. With abrasiv mat'ls, wear is excessiv.

5.7. PNEUMATIC OR "CURRENT" CONVEYORS,

in which finely divided materials are conveyed thru pipes by the movement of air currents, are of three types; (1) the pressure or blast system, (2) the vacuum or suction system, and (3) vacuum and pressure combined.

5.71. In the **pressure** system, the mat'l is introduced into the pipe by an injector by a blast of comprest air, and is blown out of the other end of the pipe into the bin or place in which it is wanted.

5.72. In the **vacuum** system, the mat'l is suckt in by means of a partial vacuum produced at the delivery end of the pipe. The mat'l is carried along the pipe and enters a large chamber which reduces the velocity sufficiently to permit it to fall to the bottom.

5.73. In the **vacuum and pressure** system, the mat'l is suckt in thru a nozzle and travels thru a pipe to one or two large chambers, where the mat'l settles. If only one chamber is used, a rotary or alternating air-trap is provided at the base, which feeds the mat'l from the chamber with partial vac to another chamber under pressure, from which the mat'l is blown thru the delivery pipe to the place where

it is wanted. Where two chambers are employd, they are causd to alternate their functions of receiving the mat'l in partial vac, and of blowing it thru the delivery pipe under pressure.

5.74. The **intake** end of the nozzle may be carried by a crane or derrick which can lower it into the bin or ship's hold from which the mat'l is to be taken, and move it around until all the mat'l has been suckt up, or the nozzle may be on a length of hose or flexible pipe which may be moved about by one man.

5.76. **Utility.** In general, any fine or powdery mat'l can be handled if not sticky or friable, such as grain, certain chemicals, fine coal, ashes, lime or cement. Pneumatic conveyors are distinctly inefficient as regards power consumption, but they are by far the easiest type of long haul conveyor to instal or shift from place to place, delivering as far as 500′ or more, requiring only pipes as conveyors, and one man at each intake nozzle. They serv very well in unloading box cars containing cement in bulk, effecting complete clean-up.

6.0. VEHICLES

6.02. **Classification.** We find a very great variety of combinations of machines and devices. Indeed, the practising engineer may often devise other new and useful combinations.

From 6.1 to 6.3 incl (wheelbarrows, carts and wagons), we treat of vehicles utilizing hand or animal power only; and from 6.4 to 6.7 incl, (automobiles, trucks, tractors, trailers, cars and locomotivs), those employing such power as steam, gasoline, oil, etc.

6.1. WHEELBARROWS

See also p 1027, Art 10, and p 1034, Art 15.

6.11. **Construction, dimensions,** etc. Wooden wheelbarrows weigh abt 50 lbs each, and are not very durable. Steel barrows, with trays of stampt steel, some with wooden handles and frame, weigh from 65 to 90 lbs each. Aluminum alloy barrows weigh abt 35 lbs, the saving in wt over steel barrows making poss the addition of from 30 to 55 lbs of load carried. Wheels are usually 15″ in diam, tho some are as large as 18″. The larger the wheel, the easier the rolling over rough ground, but the ht of the load becomes objectionable. Some barrows are equipt with pneumatic tires, and are claimd to require no plankways. The man wheeling a barrow may have to hold from 1/5 to 1/3 the load.

6.12. **Capacity.** Barrows are built to contain from 3 to 6 or even 8 cu ft of material, but in practis the amt carried depends chiefly upon the wt of the mat'l. Only 1½ to 1¾ cu ft of concrete can be carried, or 2 to 2½ cu ft of earthy mat'ls, equivalent to abt 180 lbs, tho some authorities allow 3 or even 4 cu ft.

6.13. **Utility** is confined to short hauls of a few hundred ft, and to small quantities, and to cases where more efficient equipment cannot be employd. Barrows must be expected to receive very hard treatment, so that cheap ones are very uneconomical.

6.14. **Operation.** It is usually nec'y or very desirable to provide plankways 2″ thick and as wide as obtainable. If practicable, it is best to arrange the work so that the bar-

row may be dumpt from the side. Time is saved if the barrow is not reverst and only the man turns around at the end of the run. On a heavy grade, a horse may sometimes be employd to assist by pulling with a rope.

6.2. CARTS

may be of use when power trucks or tractors and trailers are not available. Three types have predominated, as follows;—

6.21. Those referd to on pp 1024 *et seq* have wooden wheels 5 or 6 ft in diam, wide steel tires, a wooden box body with a cap of from 18 to 27 cu ft, pivoted at the middle of its base for dumping from the rear by withdrawing a locking-bar, the frame being provided with two shafts for a horse.

6.22. Push-Carts or Concrete Buggies now (1937) available for transporting concrete, coal, coke, earth, etc, for short dists, have steel wheels from 20″ to 40″ in diam (some pneumatic tired), with a steel body with capacity of 6 to 11 cu ft, and a handle for operation by hand, the body being so pivoted as to be readily tipt forward for dumping, with feet at the rear for keeping it level when standing.

6.23. The **pick-up cart** consists of two wheels from 45″ to 60″ in diam, 3″ tires, with an axle bent like an inverted "U", to the top of which is rigidly attacht one end of a long lever, with a hook on each end. It may be of use in picking up and transporting heavy objects (up to 5 tons) such as pipe. By raising the free end of the lever, the other end is lowerd. The object is then attacht by rope or chain, and lifted abt a ft from the ground by pulling down on the free end of the lever, when it may be moved about over fairly even ground

6.3. WAGONS

Like carts, wagons pulled by 2 or 3 horses may be of use where power vehicles are not available. They were used with satisfaction by the Miami Conservancy District (report of 1925, p 236) over loamy silt or light sand, where power trucks had trouble, especially when the ground was wet. **Speed,** abt 240′/min = 2¾ mi/hr.

Ordinary wagons are inefficient because the material hauld must be shoveld out. **Dump** wagons have been built of varius types; those with a floor of removable long'l wooden bars, called pole wagons (which must be stopt to unload); with hopper bottom, and with body tipping backward like a dump cart.

Capacities range from 1¼ to 2 cu yds.

See also section 6.6, Trailers.

6.4. AUTOMOBILES

6.41. Passenger

automobiles are generally too well known to warrant description here.

For **Tires,** see sec 1.55.

6.411. Cost of Operation, as determined by many who have made records of experiments and regular use, *appear* to vary widely betw 3 and 13 c/mi. Much of the variation is due to use of autos on different kinds of roads, and to diff speeds, but much is nec'y due to the combination of time costs (such as garage, interest, insurance and lisences)

with distance costs (as gasoline, oil, tires, maintenance and depreciation). Depreciation, taken as diff betw buying and selling costs divided by mileage coverd, may be from 1 to 3 c/mi. Taking depreciation as 2 c/mi, the total expense due to **distance** over **high-grade roads,** as given by varius writers, usually ranges within 4¼ to abt 5 c/mi, gasoline consumption being taken as from 1 to 1.6 c/mi. The expenses due to **time,** are best computed by the user, and when known they may be combined with the distance costs, resulting in a **total** cost of anywhere from 5½ to 10 c/mi or more. Note that if one drives comparativly little, say 2000 mi/yr (or 5.5 mi/day), and has time expenses of say $80/yr or 4 c/mi on an *average,* then the cost of a trip of several hundred miles covering only a day or so, will be primarily a distance cost of perhaps 5 c/mi, instead of 5 + 4 = 9 c/mi.

6.412. Weight of a passenger auto may be from 2500 lbs to 4500 lbs (1¼ to 2¼ tons) the more usual machines weighing around 3000 lbs (1½ tons).

6.413. Resistances. Different experiments conducted by different persons, using diff autos, naturally give rather divergent results. The following table gives approximate figures only, for passenger autos on level concrete or other high-grade road, assuming front projection of auto as 30 sq ft.

Speeds, mi/hr	10	25	40	60
Total resistance, lbs*	75	105	155	340
Air resistance only, lbs†	6	37½	96	216
" " (**"streamlined"**) lbs‡	2	12	31½	71
One **stop-and-start,** cost, cents¶	0.056	0.134	0.215	0.330

Road resistance. Gravel roads may be expected to increase cost of operation (over that on conc roads) from 20% to 40%, according to different authorities.

Grade increases resistance by wt of auto × sine of angle.

6.42. Trucks

are mfd in great variety of sizes, **capacities** varying by tons or half tons, four-wheeld trucks ranging from ½ to 10 tons, with chassis **weights** (without bodies) from 2200 lbs to 7000 lbs, 6-wheeld trucks, cap from 1½ to 12 tons or more, and chassis wts from 5000 lbs to 10,000 lbs. **HP** from 75 to 125 and higher.

Tires, see sec 1 55.

6.421. Speeds. Loaded trucks ordinarily make speeds about equal to passenger autos over the same kinds of roads, except where up-grades are encounterd, but seldom much over 50 mi/hr.

6.428. Utility. The ability of a truck to travel almost any road or fairly firm surface, without the need for construction of tracks, to transport widely different objects, and so minimize idle time, and to go usually to the exact spots where loading and unloading are to be done, without changing the load from one conveyance to another, makes it of great service to the C E. But its

---

* Derived from data in Bull 119, Iowa Engg Expt Sta, by R G Paustian, '34 Aug 1.

† Derived from Kansas State Agr Coll Bull No 18, '27 Dec 15, by L E Conrad and E R Dawley. Air resistance varies very closely as the square of the speed.

‡ Deduced from U S Buro of Standards Research Paper RP591.

¶ Expts by T T Wiley, Civil Eng'g, '35 May, p 286.

6.429. Operation is very important. Where even small fleets of trucks are used, there should be men and equipment devoted solely to maintaining the trucks in good condition, and in **maintaining temporary roads** so that they may be used without trouble or undue delay even in bad weather. On certain extensiv dam building operations, fleets of scores of trucks have been used for conveying earth, traveling 40 mi/hr at intervals of only a few hundred feet. The selection of drivers is very important.

6.4291. Costs of operation. The following are taken from bulletins issued by the Economic Dept of the Coll of Agriculture, Cornell University, Ithaca, N Y, and relate to trucks used in central N Y state.

Averages of 43 trucks, averaging 6615 mi/yr each, 1935, showing effect of **size** of truck,—

Capacity of truck, tons.	½ & ¾	1	1½
Depreciation, fuel, oil, and repairs, c/mi	2.7	3.9	5.9
Other costs, c/mi	1.0	1.8	1.6
Totals, c/mi	3.7	5.7	5.9

Averages of 19 trucks, 1 ton capacity or less, 1935, showing effect of **mileage** per year,—

Miles per year	10,000	3,000
Cost per mile, cents	3.1	11.5

Average of 47 trucks, approx 6 c/mi.

6.43. Dump Trucks

are little more than ordinary trucks with provision for dumping the containd material to the ground. Almost every possible method of dumping is available, almost always by power taken from the engin. The front end may be raisd to as much as 70° from the hor, the tail-board releast, and the mat'l dumpt from the rear. This is in some cases assisted by a false bottom, known as a kick-out pan, lying on the bottom of the body, so hung by chains at the lifted end that it swings free to an almost vert position. Or the body is tilted to one side or the other, the lower side being releast. Some have hopper bottoms. Bodies are usually of prest steel.

6.431. Horse-power provided is usually betw 75 and 100. **Speeds** were formerly kept down by governors to abt 15 mi/hr, but are now generally unrestricted and are almost if not quite equal to those of ordinary trucks. **Weights** from 11,000 lbs to 14,500 lbs. **Capacities** usually range from 1½ to 4 or 5 tons, and as high as 10 or 15 tons; or 1½ to 4, 5 or 6 cu yds, and as high as 12 cu yds.

6.435. "Dumptors" or "Iron Mules" are a special type of dump truck, usually of very short wheel-base, in which the driver sits behind the body and faces forward over it, making possible quick sharp turns within 15′, and also indefinit revers running, as the driver has a completely unobstructed view to the rear. **Speeds** of 20 mi/hr are claimd for some, tho 10 to 13 mi/hr in high gear and 3½ to 4 in low, in *both forward and revers* gear, seem more usual. **Weights** from 13,000 lbs to 18,000 lbs. **Capacities**, 5½ cu yds and less.

6.44. Tractors

The use of caterpillars or crawlers with tractors is so usual that "caterpillar" is often used to denote "tractor."

6.441. Construction. The tractor is a unit of great compactness, combining an engin mounted on a frame carried usually by caterpillars, (see sec 1.56) abt 5 or 6 ft apart, (occasionally by wheels, as for farm work), with a coupling in the rear for pulling.

6.442. **Power** is usually gasoline or oil or Diesel engin, and may range from abt 25 to 95 HP, in some cases as high as 125 and even 160 HP, 50 to 70 HP being the most usual and generally practicable. The following figures are approximations from data supplied by one of the foremost mfrs;—

	1st gear	2nd gear	3rd gear
Draw-bar pull, in lbs, largest ..	22,000	15,000	13,000
" " " " smallest ..	4,000	3,000	2,000
Speed, mi/hr, average	2	2¾	4

6.443. **Weights** range from 5,000 lbs to over 30,000 lbs, 11,000 lbs being abt the av. **Unit wt on ground** is very close to 6 lbs/sq inch for all sizes, the caterpillar treads being so proportiond as to keep near that figure.

6.444. **Speeds** in mi/hr = approx 0.5 + the number of the gear. Thus, in 3d gear, speed = 0.5 + 3.0 = 3 5 mi/hr.

6.448. **Utility** is very great, becaus almost anything may be hitcht to a tractor and puld. The machine can travel over almost any surface, negotiating steep grades, as was done by the "tanks" in the World War. A tractor may be used for hauling disc plows, gang plows, scarifiers, scrapers, graders, ditchers, elevating graders, trailers (wagons or buggies), for logging, road grading, maintenance and construction, for almost any purpose requiring a strong slow hor pull, even such as pulling down old structures or moving buildings, and, by the addition of a blade in front, for bull-dozing and snow plowing.

6.449. **Costs** of operating tractors. The following figures are from varius bulletins of the Economic Dept of the Coll of Agriculture, Cornell University, Ithaca, N Y, reporting, 1935, on abt 70 machines, from 16 to 30 brake HP. Extremes were 25c and $1.12 per hr, avs from abt 50 to 70 c/hr.

6.45. Tractor Trucks

A tractor truck is a combination of a power truck and "**semi-trailer**" carrying the load.

6.451. The **power unit** consists of an automobile truck, comparable in wt and HP to trucks in which the body contains the load. The rear portion, however, is a low platform carrying the lower half of a vert pivot.

6.452. The **load-carrying unit,** or semi-trailer, has no running wheels under its front end, but instead the upper half of the pivot, resting on the rear of the truck. The pivot is arranged to permit the truck to turn 100° or more hor'y either way under the semi-trailer, thus affording great maneuverability in spite of size, and is also arranged to permit tilting of the units with respect to each other when traversing uneven ground. Just back of the pivot, the semi-trailer is provided with one or two small wheels or other supports that are off the ground when running, but which, when standing, are lowerd, and bear the wt of the front end, so that the truck may then be removed and used under another semi-trailer while the first is being loaded or unloaded. Thus one truck may serv two or more semi-trailers, depending upon the ratio betw loading and running times. These semi-trailers, having to provide no room for engin or cab, are made up to very large sizes with great capacities Since the semi-trailer delivers only half its wt onto the rear wheels of the truck (and half to its own rear wheels) it may have about double the ordinary capacity of such a truck. The added load nec'y reduces the speed and the grades that can be surmounted, tho air-brakes on all wheels afford almost as good control going down hill as the truck itself would have.

6.6. TRAILERS, "WAGONS" or "BUGGIES"

In many cases, trailers have been specially built for particular cases, such as the 194-ton trailer for Boulder (formerly Hoover) dam, (Roads & Sts, '34 Mar), and many others too numerus to list. These nec'y have many wheels under them to carry their loads, and in some of them the wheels are steerd by power. For carrying long girders, a trailer may consist of merely two trucks (of 2, 4 or more wheels each) connected to each other by the girder itself, which is lasht to them. Large bins for cement, aggregate, etc, have been mounted on wheels, that they may be towd from place to place (provided there is head-room).

The usual trailers, however, have become well standardized, tho of many types. They should be hung low, to minimize chance of overturning while being towd, and to make it possible for elevating graders to deliver into them. The use of wheels (up to 8 or 16) is about as usual as the use of caterpillars. **Capacities** may range from a few cu yds each to 24 or 30 cu yds in the larger sizes, capable of carrying loads of from 20 to 35 tons. **Trains** of two trailers or "buggies" (often on caterpillars) are frequently used, tho more than two increases difficulty and danger of maneuvering. They are often or usually provided with means for **dumping** in one manner or another.

6.7. INDUSTRIAL RAILWAYS

may be of use to the C E when there is much hauling to be done over a long fixt route, as in constructing RRs, highways, dams, tunnels, aqueducts, canals and sewers. In some cases it may be well to operate the cars by means of a cable, especially where grades are over 3%. Greater flexibility, however, is obtaind by the use of locomotivs or motor cars, tho grades of over a few per cent will seriusly limit the wt of cars that can be hauld. Electric motor cars have been operated by remote control over track divided electrically into separate sections.

6.71. Track

Gage is usually 18″, 24″ or 36″, some 42″. **Rails** may weigh almost any even figure from 8 to 20 lbs/yd, or any even ten pounds from 20 to 70 lbs/yd, and come in lengths of 20, 30 or 33 ft. Second-hand rails and ties (worn but not defectiv) will often serv well to construct such track, especially if it is not to be used over a long time. **Portability** is usually of great importance as the work progresses, and light track is to be had in which ties and rails come ready assembled in lengths of 15 to 20 or even 30 ft, that can be carried by 2 or 3 men, with curvd sections, switches and turntables; having joints that may redily be fastend and unfastend. Such track can be laid on firm ground with very little if any grading. **Ties** may be of wood, but steel is better for portability.

6.72. Motiv Power

6.721. Power. Animals may sometimes be used to advantage where mech'l power is not available. Steam has been largely displaced, as has "fireless" (steam storage), and comprest air power. Power now used (1937) is chiefly oil or Diesel, gasoline, gasoline-electric, electric storage battery, electric trolley or third-rail, depending upon facilities available. **HP** from 50 to 200. **Speeds** are not generally high, 2 to 12 mi/hr for gasoline.

6.722. Weights of locos available vary by very small differences from 2 to 35 tons, up to 50 or 60 tons.

6.723. Tractiv Effort. The power employd is usually suff to slip the wheels on dry rails when starting, so that the practical tractiv effort will be equal to the wt of the loco or motor multiplied by the coeff of fric. This coeff may be counted on in theory at least as 0.20 for dry rails, tho 0.35 may be achievd with sanded rails; while on wet or greasy rails (without sand) it may be as low as 0.15 or 0.10 or much less. The **draw-bar pull** = tractiv effort — force (= abt 8 lbs/ton of loco on well laid track) req'd to move loco. As speed is increast, the propulsiv force of almost any power diminishes, so that the hevier the train, the lower the max speed possible. What is said in sec 1.55 about **avoiding slipping** applies also to steel wheels and rails.

Caution. A loco **and train** will not be able to negotiate a grade equal to that which the loco alone can manage, but only that grade multiplied by the wt of loco alone, divided by the wt of loco and train. Thus, where a loco alone can operate on an 8% grade, it can handle a train of its own wt on grades of only half that, or 4%. Altho the operation of a loco may approach the theoretical coefs of fric, yet **in practis** a very little water or grease on a short length of rail may so reduce the coef there that the wheels may skid and the machine or train become unmanageable.

6.729. Operation, as in standard railroading, should be by careful and competent men only.

6.73. Cars

for use on industrial rys may have only a platform, a box body, or any of a great variety of forms for handling special objects as logs, brick, ore, concrete, etc. **Dump** cars may be bottom-, side- or end-dump, and of many different designs. **Sizes** vary from 4-wheeld hand-cars up to 8-wheeld (two-truck) cars of standard RR type. The bodies are usually made of steel, prest or welded.

6.8. TURNTABLES

Portable turntables have been available, with a short ramp on one end, onto which trucks or other vehicles may be run, and then turnd around in places too narrow for the vehicle to turn itself, such as that half of a roadway not under construction.

7.0. OTHER EXCAVATORS

in addition to those described in sections 1, 2 or 5.

7.1. PLOWS

7.11. Construction. A plow consists of a pointed "share" which divides the earth, and above it a "moldboard" so curvd as to throw the earth to one side. On the opposit side is the "landside" which prevents the thrust of the share and moldboard from deflecting the plow. These are attacht to a frame or "frog", to the rear of which handles are attacht for hand plowing, and to the front of which is fastend a "beam" to which horses or a tractor may be attacht, and to the under side of which a "gage wheel" is sometimes fixt to control the depth of cut.

7.12. Types. The **rooter plow** or **subsoil plow** has no moldboard, is much sharper, and is used to loosen particularly hard ground. A **gang plow,** mounted on wheels, carries three or more plows to cut as many furrows. In the **disc plow** a concave, edged, steel disc, mounted on edge

in the plane of motion, replaces the moldboard plow, and is especially adapted for sticky or very hard dry soils.

7.13. Furrows may be cut from 4″ to 12″ deep. In shaly rock 7″ or 8″ is about all that can be attempted. Width of cut, 12″ to 14″ for deep cuts, and less for shallower cuts.

7.14. Weights of farm plows are usually somewhat over 100 lbs; while contractor's plows weigh from 180 lbs to 430 lbs.

7.15. Power may consist of from 2 to 12 horses, while some plows are rigged to be attacht to a tractor.

See also 7.5, Elevating graders.

7.2 ROOTERS

A rooter is similar to the harrow used by farmers, but much stronger, to withstand the stresses imposed by being dragd by a tractor, and by deeper and harder digging to depths of abt 2 ft. It is mounted on a pair of wheels from 2 to 3 ft in diam The number of **teeth** is much smaller than in the harrow, being as high as 9, tho more usually 5 or 3, with provision for leaving only 2 or 1 for digging. Some are claimd to be so designd as to be self-sharpening until worn out. **Weights** may be anywhere from 2500 lbs to 8000 lbs.

Rooters seem to have their greatest **utility** in making ready ground for bulldozers (sec 7.3) and graders (7.4) where it is very hard or stony, consisting of boulders or decomposed rocks. They are of use also in dislodging stumps, or breaking up concrete. It is claimd they frequently obviate blasting.

7.21. Scarifiers

are similar to rooters. They consist of a series of vert teeth mounted in one line on one bar, which may be used in place of the blade of a grader (7.4) or may be attacht to the rear of a road roller. Their **utility** lies in their ability to break up hardend surfaces, and to break off high spots of uneven ground.

7.3. BULLDOZERS, TRAILBUILDERS

7.31. Construction. A bulldozer consists of a self-propelling unit, usually running on caterpillars (sec 1.56) tho sometimes on rubber-tired wheels, powerd by gasoline or Diesel engin; provided with a very strong blade.

7.311. The **Blade or Scraper** is of steel, oblong, mounted in front of the caterpillar or wheels, its longer axis hor. It is usually held at rt angles to the line of motion, but in some makes may be placed at any hor angle up to 30°, right or left, to throw dirt to one side, and it may also be tilted from the vert to better suit different kinds of earth. The lower side carries a cutting edge of specially hardend steel, while the main portion of the blade is usually more or less concaved to carry along as much mat'l as possible. The blade is arranged to be lifted as much as 3 or 3½ ft, and lowerd 5 or 6 ft below the level of the ground on which the machine may be operating.

7.312. Weights of such machines run from 3500 lbs to 6000 lbs. **Capacities** when loaded for shoving, 2 to 4 cu yds. **HP,** 30 to 70.

7.318. Operation frequently consists of an initial movement of 25 to 40 ft at abt 2 ft/sec, in which the blade is lowerd and the mat'l scraped up; and then a hauling or shoving movement which may be as long as 300′ at abt 3½ ft/sec, with the lower edge of the blade at ground level.

After depositing the mat'l where wanted, the return may be made with the blade raisd, at full speed, say 4 ft/sec. If the **material is hard,** it should first be gone over and loosend with a rooter. Experiment should determin the best speed for shoving, as it is usually possible to travel fast enough to lose much of the mat'l.

7.319. Utility. The bulldozer is of use for clearing, maintenance of roads, spreading mat'l, making fills, making paths for trucks, shovels, etc, but the **mat'l must be fairly loose**, without soft pockets, without rock, and the haul not too long. They are particularly effectiv scraping *down* slopes as steep as 35% to 45%. If the gear is right, they may be *backt* up the grade for the next operation.

7.4. GRADERS

7.41. A grader, also known as **blade grader, road shaper,** or **maintainer,** consists essentially of a blade or moldboard mounted on a frame on wheels, much as in a bulldozer except that the blade is betw the front and rear wheels instead of in front of all the wheels.

7.42. Power. Graders may be either powerless, to be puld by animals or a tractor requiring 15 to 80 HP; or they may be propeld by their own power, which is usually around 50 HP, using 4 steel wheels, or 4, 6 or 8 rubber-tired wheels, or caterpillars, for propelling.

7.43. The **Blade or Moldboard** is furnisht in almost any length from 7 to 16 ft, or less when horse-drawn, 12 ft being usual, with a ht of abt 18″. The blade is adjustable in ht, hor angle and tip.

7.45. Weights may be as low as 1400 lbs in graders to be towd, and as high as 17,000 lbs or more in power machines. **Speeds** of power machines are usually abt 2 mi/hr in low gear, and 10 mi/hr in high gear, with two intermediate gears, and reverse.

7.48. Utility. Graders are not essentially excavators, tho they may do a moderate amount of cutting. They are chiefly levelers or eveners, and are used largely for maintaining the surfaces of earth roads, and ditches and banks; taking displaced mat'l and shoving it along until it finds low spots to lodge in.

7.49. Leaning-Wheel Grader

In this the wheels may be leand to one side or the other as much as 25° or 30°. This is of value (1) in opposing the thrust of the blade when forming banks, and (2) to keep the wheel-treds hor when it is working on steeply sloping ground. The blade may be swung out to the side (its plane approx at rt angles to the line of motion) and set at different positions and vert angles for the forming of banks as high as 8 ft. Or it may be set low so as to partly cut and form small ditches.

7.5. ELEVATING GRADERS

are *not* a development of graders, but are a combination of plow and conveyor mounted on a frame carried by wheels or caterpillars.

7.51. The **Plow** may be either of the moldboard type, or both disc and moldboard in series, capable of cutting a furrow abt 1′ wide, and 6″ to 7″ deep. The moldboard delivers the broken-up mat'l onto the lower end of a small

7.52. Conveyor or **"Elevator"** of changeable inclination, (usually of the belt type, tho buckets have been used) from 14 to 25 ft long, the belt being usually 42" or 48" wide. It is mounted at rt angles to the direction of motion, extending outward to the right or left, and upward suff'y to deliver over the top of a wagon or truck moving alongside and keeping pace with it.

7.54. Power. Either horses (as many as a dozen) or a tractor (around 75 HP) may be used for traction. The conveyor may be operated either by a separate power unit on it, which makes belt speed control easier, or by a "power-take-off" from the wheels or tractor, which is simpler and lighter.

7.55. The **Weight** of such a machine may be around 15,000 lbs.

7.56. Capacity will vary greatly according to the kind of mat'l encounterd, but will usually be over 1000 cu yds per day, while some mfrs claim that about 3000 cu yds per day have been handled.

7.58. Utility. These machines can be very servisable on even level ground of uniform plowable loam, sandy soil, or gravel, for the forming of canals, irrigation and other ditches, and levees, and for RR and highway construction. They are said to be particularly helpless on wet ground, being unable to handle wet or sticky mat'l, and especially so among rocks or boulders or roots, in hard-pan or deeply frozen ground, or where there are abrupt grades.

7.59. Operation. Unless the conveyor is delivering mat'l directly to the tops of levees or other embankments, the servising of the machine by the optimum number of wagons or trucks is most important, as changes in hauling dist may call for more or fewer vehicles.

7.6. TRENCHERS AND DITCHERS

7.60. Definitions. Engineers seem to make a quite definit distinction between trenches and ditches (tho not perceptibly indicated in dictionaries), a trench being comparativly narrow with vert or nearly vert sides, and the ditch being much wider, with side slopes of say 1 on 1 or flatter.

7.61. Types. Almost any excavating device may be used and has been used for digging trenches and ditches. Years ago, cableways were much used, strung over the line of the trench, some handling a number of buckets which were loaded by men digging in the trench. These may be used effectivly if nothing else is available, and they can be used for deeper digging than the machines described below. In at least one case, a power shovel dug and deliverd to a belt conveyor that carried the mat'l along for back-filling. A power shovel mounted on a flat-car is frequently used by RRs for maintaining the ditches alongside their tracks. Two types of machines using **buckets for digging** as described below, have been specially developt for trenching and are largely used. But where these are not available, the machine most generally resorted to is the **pull-scoop** or back-digger (sec 1.17).

7.62. Bucket-Wheel Trenchers

7.621. Construction. Fig. 13. An engin, *E*, (formerly steam, but now generally gasoline or oil) is mounted on a frame carried by wheels, *W*, or caterpillars, *C*, or both. Extending from the rear is a large vert wheel, *L*, *L*, which carries a series of buckets, *B*, *B*, equipt for cutting. There is also a belt conveyor, *V*, as in elevating graders (sec 7 52). The engin is geard for driving the entire machine ahed at varying speeds, for rotating the bucket-wheel, and for operating the conveyor. The wheel, *L*, has no axle, but is a circular frame rotating on three or more rollers, *R*, *R*, and the buckets, on reaching the top, dump inside the circumference of the wheel thru an opening in a fixt ring (not shown) which the wheel embraces, onto the conveyor which extends in to abt its center. Where tile or pipe is to be laid, or other work done in the trench directly behind the machine, not only may the sides of the wheel be enclosed to prevent the sides of the trench from falling in, but there may be carried behind the wheel a large hollow box, *X*, in which the workmen may lay their pipe with a fair degree

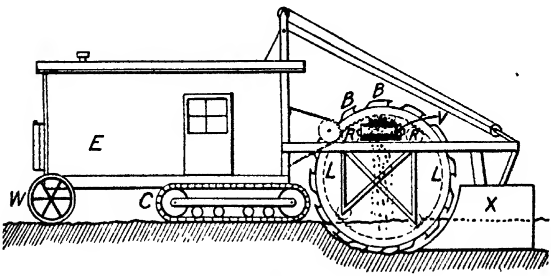

Fig. 13. Bucket-Wheel Trencher

of protection. In some machines the wheel (without the protecting box) has been arranged to be turnd right or left abt 20°, so as to excavate a ditch rather than a trench.

7.622. Depth of Trench which bucket-wheel machines can dig, is from 8 to 12 ft max. The **width** may be from 12″ to 28″ or as much as 42″, altho 12″ or even 15″ is too narrow for men to work in efficiently, so that 18″ or more is usual.

7.623. The **Conveyor**, *V*, which extends out at rt angles to the right or left, to deliver the excavated mat'l either in a long pile at the side, or to trucks, is usually of the belt type, (sec 5.1) of ordinary width, from 20″ to 30″.

7.624. HP, from 25 to 100. **Speed** or feed, in ordinary earth, from 1¼ to 4 ft of trench per min, in exceptional cases as high as 5′/min, while partly frozen ground may slow it down to ½′/min.

7.63. Bucket-Chain Trenchers or Ladder Excavators operate much like ladder dredges (p 581*l*, paragrafs 72, 73 & 74).

7.631. Construction is much the same as that of bucket-wheel trenchers, except that a chain carrying buckets takes the place of the wheel. The course of the chain of buckets has been different in different machines, having either a triangular or elliptical outline as seen from the side, while in some machines the forward buckets are moved downward in a vert line, forming a vert face to the trench. Some machines are so designd as to be able to cut a trench only a fraction of a foot from the foundation wall of a building.

Depth of trench which bucket-chain trenchers can dig, is from 12′ to 20′. **Width** of cut is about the same as in bucket-wheel machines. The **conveyor** is arranged as in bucket-wheel machines. **HP**, from 30 to 70. **Speed** or feed, from 1¼ to 5 ft/min.

7.64. Operation of bucket machines (either type) is usually accomplisht by two men with the machine. Others must of course be employd for laying the tile, pipe, cable, or whatever is to be placed in the trench, as well as for back-filling. One of the **main objects** in the design of these machines is to minimize the time that a trench must be open; particularly important on roads or streets.

7.65. Utility of bucket machines is likely to be limited if hard rocky ground is encounterd, advance blasting frequently being required. The figures above, sec 7.624, for speed, are for earth, gravel, tough clay or sand. Trenchers are particularly useful for laying water, sewer, gas or oil pipe, or telefone cable. Pull-scoops (or "back-diggers") (sec 1.17) are very largely used in place of bucket machines.

7.66. DITCHES (meaning wide trenches with sloping sides) may often be dug with other excavators, such as power shovels, or even clam-shells if the ground is soft enough, and especially by pull-scoops. Leaning wheel graders (sec 7.49) are largely used for shallow ditches, while shovels operating from RR track do much of the maint of RR ditches.

7.8. HYDRAULIC EXCAVATION or HYDRAULICKING originating chiefly as a means of surface mining, consists of squirting large quantities of water at high pressure thru a large nozzle, against the material to be excavated.

7.81. Water Supply. In some cases suff water may be obtaind by **gravity** from some not too distant source at a higher level. In other cases it will be necessary to **pump** the water, centrifugal pumps being usual and efficient, making possible the use of salt or gritty water. The **head** req'd will be several hundred feet. As little as 80 or 100 ft head has been used for washing mat'l away, but usually less than 200′ will not be satisfactory for cutting, while 300 to 400 and even 600 ft head are used where poss. The **quantity** of water used will be determind by the head and the size of the

7.82. Nozzle, "Hydraulic Giant" or "Monitor" used. According to Peele's Mining Engineer's Handbook, we have approx'y;—

Diam of nozzle, inches................	1	3	6	9
Flow under 200′ head, cu ft/min......	33	250	1500	2700

Diams of nozzles vary from ¾″ to 10″. Experience indicates that a number of smaller nozzles are more effectiv than a very large one, altho an 8″ nozzle, using 3600 cu ft/min, has excavated 800 cu yds/hr. The nozzle must be **fastend** to the ground in some firm manner, to resist the great reaction from the escaping jet. The base of the nozzle is attacht to the supply pipe by a swivel **joint** that will permit considerable changes of direction. A small nozzle may be directed by hand by a long handle extending back to the rear; but the larger ones will usually require a **deflector.** This may consist of a short tube, larger than the nozzle, surrounding the front of the nozzle and extending a short dist in front of it, and so mounted as to be turnd slightly by hand in different directions, so that the jet strikes its inside surface on one side or the other, the reaction being suff to turn the nozzle as desired. The deflector is then again turnd straight ahead. The **bore** of the nozzle should be very smooth and even, as slight roughnesses will break part of the jet into spray, losing much of its force.

7.83. **Sluices** used for carrying away the mixture of water and earth usually require a grade of 4%. Sometimes a mere gully, reinforst on the sides by planks, will be suff, but it is usually better to provide a wooden or metal flume, especially as it is easier to shift as the work progresses.

7.84. **Capacities.** Records of mat'l excavated in given times are often unsatisfactory because some factor is not given. It has been found, however, that the proportion of solids that the water will carry ranges betw 6 and 20%, with 11 or 12% as an average. From this it would seem that the amt of excavation may be conservativly estimated and computed as 10% of the water deliverd by the nozzle or "giant".

7.88. **Utility** depends upon the head and quantity of water available, character of mat'l to be excavated, and ability to dispose of the waste. Its efficiency will be greatly increast when the waste may be used for dam construction or for making fills. **Material** excavated may be sand, gravel, earth, and even loose rock. Glacial till, hard blue clay and boulders were excavated in large quantities on a number of the Miami Conservancy works, but with some difficulty. Sometimes advance blasting is necessary or very desirable. **Freezing**, if severe, may suspend operations entirely. See also "Operation", following.

7.89. **Operation** requires care and skill. Nozzles should be kept as close to the face to be excavated as possible, altho even more **care** should be exercized to keep far enough away to avoid danger from caving. 50 to 60 ft is further than desirable for efficient cutting, altho fair work has been done at 250′ with a small nozzle. The nozzle is best aimd at the base of the wall of mat'l to be cut away, striking at a small angle. It is frequently well to have a low pressure nozzle to assist by breaking up masses that may cave down and by keeping the mat'l excavated by the high pres nozzle moving on its way to the sluice. For efficiency it is important to watch the output closely. A reduction of **solids carried** to half the max poss, may otherwise pass unnoticed.

Hydraulic excavation was used most effectivly in very large grading operations in both Portland, Ore, and in Seattle, Wash, where a hill about a half mile across was reduced by 210′ in ht, street grades being reduced from betw 7 and 15% to 5% over a dist of 800′. Much of the mat'l was sluiced to tidal flats, forming useful land as well as almost eliminating a hill impracticable for habitation.

9.0. OPERATION

In the following paragrafs on "balance", waste motions, layout, choice and maintenance of machines, and personnel; nearly every point brought out may be regarded as a *factor;* for if the efficiency of any one of them be reduced by any percentage, the resultant output will be reduced by almost if not quite the same percentage. Hence all are about equally important and none should be slighted.

9.1. FUNDAMENTALS

9.11. Balance

9.111. Machines. Perhaps the most important and comprehensiv principle to observ for ideal efficiency in the operation of equipment, where more than one machine is involvd, is that all of the several machines working in connection with each other shall "team together" as nearly as possible, and that the work of any one shall fit in with that of others as regards capacity and reliability For example, bad balance obtains when too many trucks must wait for an excavator, or too few trucks keep the excavator waiting. One machine, unable to keep up with the rest, may keep them all down to its own low rate. Or, again, if the equipment is already well balanst, the purchase and introduction of any one machine capable of working twice as fast as the one displaced, will *not* speed up the work in the slightest, and will increase maintenance cost and interest on the investment. Usually there is one expensiv "key" machine, such as a power shovel, whose output it is not practicable to change materially; and it is to this that all the other co-operating machines should be timed. **Caution:**—But see "in practis" in sec 9.3.

9.112. Material and Labor also should be kept balanst. Unless the work is well supervised, machines may be kept waiting for insufficient or incompetent men; and conversely, expensiv men may be kept waiting for machines or equipment. Lack of pipe, wire, tools, etc, may add much to man-hours req'd to overcome the handicap.

9.113. Time and Materials should be balanst so that needed supplies, as gasoline, oil, cement, food, etc, arrive at as nearly the best time as possible. Not only may lateness hold back the work, but pre-delivery may do so by cluttering up places where other things belong or where free movements of men and mat'ls are important.

9.12. Waste Motions

should be reduced to a minimum. No fixt rules can here be set down for such matters. Many books have been written on this subject alone. See section **620.e** in Bibliography preceding Index. The management must be on the watch for needless **revers movements, re-handling, excessiv travel,** such as that of an excavating bucket or the movement of a truck. Only common sense and ingenuity can here be prescribed for most of such efficiency work. Wasteful **Repetitiv Operations** should not be lost sight of or ignored, even when apparently trivial. It may be said; "It is *not* the little things that count, but the large number of them". A loss of only 3 secs in one operation of a shovel making a cycle every 30 secs, is multiplied by almost a thousand in a day's work, and means the loss of over an hour in a 10-hr day.

* 9.13. Time Studies

of machines it is proposed to use, are usually of great help in planning the work, and if kept up as each job progresses, they frequently reveal unsuspected causes of delay and inefficiency, especially valuable if of repetitiv work. Record-

ing ammeters, truck movement indicators, and other recorders and meters are valuable if used and studied, and advantage is taken of their indications.

9.14. Scheduling

should be undertaken in almost every case, especially where many machines and operations are involvd. Even tho precise predicting may be impracticable, it is usually far better than forging ahead by hit-or-miss judgment. As an aid in scheduling, we suggest "Engineering Office Systems" by John P. Davies, McGraw-Hill Book Co, New York, N Y.

9.141. Diagramming is usually of great assistance in scheduling. Many methods are available, too numerus to outline here. For this, "Graphic Methods for Presenting Facts", by Willard C. Brinton, the Engineering Magazine Co, New York, N Y, may be of value.

9.2. PLANT LAYOUT

Conditions vary too widely to permit the giving of any detaild rules for plant layout. It will depend upon topografy, materials to be handled, machines available, locations of supplies of both men and equipment, meteorological conditions, time and money available, and probably other factors. For good results, it calls for detaild planning and the ingenuity and common sense of the C E. A review of engineering periodicals may often afford valuable suggestions. See Eng & Contr'g, '29 Nov, p 443.

9.21. Surveys

are essential for all but the simplest jobs. These should be plotted to a generus scale, should include all the territory involvd, and show all objects that may be encounterd; and of especial value are **contours** accurately plotted for every few feet of elevation.

9.22. Excavation, etc,

should be pland as closely as possible. In the case of power shovels at least, diagrams supplied by mfrs (or obtainable by measurement) showing the reach, clearances, ht of lift, etc (see secs 1.14, 1.15 and 1.18) together with capacity and speed of operation, make possible close planning of the cuts to be made and estimates of time req'd.

9.23. Roads

should be thoughtfully laid out so as to serv all machines as well as possible, and to minimize their reconstruction as the work progresses, using moderate grades and curvs that will utilize the high speeds now possible with trucks. See also 9.43, road maintenance.

9.3. CHOICE OF MACHINE

will depend upon many factors, among them the work to be done, the kind of mat'l to be handled, topografy, meteorological conditions, money available, and the abilities of the machines. For this last, **see paragrafs** entitled "Capacity", "Utility" and "Operation", in each article descriptiv of each machine in question, on preceding pages.

In practis, unless the machine will be worn out when the job is done, the ideal machine for max efficiency, or even that combination of machines that produces the best balance (secs 9.11) is not always the best. Often the cost of purchasing or hiring will be prohibitiv. Even with ample funds, it frequently may be cheaper in the end to use machines already in hand, even tho rather inefficient for the purpose, than to purchase the ideal machines which cannot be sold or hired out to advantage when no longer of use on the job for which they were obtaind, particularly when they will not be used over a long period of time. Usually a

moderate sized machine will be best, because more likely to be of use on subsequent jobs. Some machines are more **versatil** than others, such as the crane, sec 1.32, and the pull-scoop, sec 1.17. Some are extremely limited, such as the bucket conveyor and the bucket-wheel and bucket-chain excavators. See also sec 0.3.

The following articles may be found to be of value. Civil Engineering, '36 Mar, p 139, Eng & Contr'g, '29 Dec, p 491. For a comparison of **draglines** with **other** devices, see article on New Madrid (Mississippi R) Floodway Levee, Eng News-Rec, '31 Apr 16. See also Construction Plant, Methods and Cost, by Chas H Paul, Miami Conservancy District, Dayton, O.

So many kinds of machines, often of increasing size, are being continually put on the market, some to endure and develop, some to disappear, that when more knowledge is req'd, we suggest that catalogs of mfrs be sent for and studied. For addresses, see advts in eng'g periodicals.

9.4. MAINTENANCE AND SERVISING

Hardly too much emfacis can be placed on the importance of ample and effectiv means for servising, maintaining and repairing machines, especially where a half dozen or more of them are in use. As pointed out in sec 9.1, the failure of any one machine may mean the stoppage of a number of others as well. One man should be in sole charge of maintenance, with no other duties. With a dozen or more machines (trucks, excavators, etc), he should have a special **machine shop** with blacksmith shop and welding equipment, and all tools and devices usually accompanying it.

9.41. Spare Parts should be kept on hand for all parts judged likely to fail, especially parts of which there are many alike, even tho it is impossible to predict accurately what may be needed; and renewals should be ordered promptly for any parts found wearing out. For small devices, as jacks, carts, tools, etc, it is well to have complete duplicates on hand.

9.42. Oiling and other routine **servising** may well be done by schedule, at lunch-time, betw shifts, or at night, making thoro **inspection** of machinery, of chassis and tires of autos. Where only trucks are involvd, they may be required to report regularly to one or more gasoline stations having water, comprest air, oil, tires, etc. Where less mobile machines are in use, as power shovels, cableways, etc, trucks should be specially appointed to deliver these things to all machines on regular trips.

9.43. Road Maintenance is of equal importance now that trucks are very greatly depended upon. They should be kept well surfaced at all times.

9.5. OPERATION OF CRANES, ETC

The following points, likely to be overlookt, and regarded as especially important, are taken from the Code of Safety Standards for Cranes, prepared by the Am Soc Mech Engrs, and agree closely with rules by Assd Genl Contractors of America.

Proper provisions for strength shall be made for all parts subject to impact and rough usage. No cast iron.....except .....drums, bearings, brackets. Gears.....shall be provided with standard gards. Drums.....shall have a flange at each end. Not less than two full wraps of hoisting cable in the groovs when...at.....lowest position.

Cranes shall be operated only by the regular crane operators. Operator should not eat, smoke nor read when operating,...nor operate....when....physically unfit. Someone specially designated should lubricate all working parts.

Cranes shall be examind daily for loose parts or defects .....(and) kept clean. Avoid.....swinging loads over workmen. On electric machines, close no main switches until sure no one about, and that all controllers are off. When leaving machine, thru all switches off.

The operator shall not make side pulls with the crane ....lower carefully. When handling max loads....test the hoist brakes after the load has been lifted a few inches; if the brakes do not hold....lower....and....adjust or repair.

Operator shall recognize **signals** only from the one man who is supervising the lift. The following are among those recommended by the Am Ry Bridge & Bldg Assn;—

Hoist; forearm vert, making small hor circle with hand.

Lower; wave forearm downward.

Stop; hold hand level with hip.

Emergency stop; hand level with hip, move hand right and left.

Raise or lower boom; point up or down with thum.

Close or open clam; close or open hand.

9.6 PERSONNEL

Another factor of great importance in operating machines is the character and ability of the men employd. They must be both competent and careful—able and willing. Careless or unskild men will probably kink cables, batter buckets and shovels, jerk hoisting lines, thus introducing dangerus stresses or overturning machines, overload conveyors, abuse autos and trucks and their tires, cause unnecessary breakages and consequent inordinate delays; neglect lubrication, loose bolts and worn parts; leav ragged excavations or sides so steep they cave in; hinder an entire plant by lateness, or slow it down by indolent work, or injure men by careless handling, or cause dissatisfaction among the other men; all of this resulting also in increast "turnover" and its expense. Altho their practical experience may give them certain knowledge the C E may not have, yet when they feel that no one can know more or do better than they, they become dangerus. A careful and expert man will probably save very many times the increase in his pay; will be willing to work hard and do overtime if necessary, being content and even eager to remain on the work, acquiring an interest in it, and will respond favorably to decent treatment and respect, and to efforts to maintain his health and happiness.

9.7. DISASTERS

such as war, revolutions, strikes, tornados, shipwrecks, floods, long rains, rock-falls and land-slides, failures due to errors in computation or construction, fires, explosions of gasoline and dynamite, epidemics, "rackets" and financial "depressions", may add tremendusly to the cost of a project, and delay it indefinitly. Probably it is practicable to insure only against fires, tornados, shipwrecks and epidemics. Floods may usually be predicted in time by receiving prompt reports of heavy rains and snow meltings from rain-gage or river-gaging stations back on the water-shed. Rains which may delay work for weeks at a time cannot be predicted. Chance of error may be minimized by ample checking, while watchfulness and care should be maintaind against construction failures, explosions or epidemics. The engineer may often be on gard against depressions by a study of financial and business curvs of the past 50 or 100 years or more.

9.9. COSTS

9.911. In sec 6.411 we were able to give fairly definit costs of automobile operation by considering distance-costs and time-costs separately, as applied to level high-grade roads only; and from these the reader may obtain the tot cost for any particular case by merely adding the two costs, and then making allowances for other surfaces and grades.

9.912. When it comes to total costs of *earthwork*, (excavating and conveying), it becomes increasingly difficult to give figures that show any sign of agreement, because of the many more elements or factors in the more complex operations. There may be any one or more of many kinds and sizes of excavator used, the mat'l encounterd may be anything from mud to rock, the work may be in open country over wide areas or trenching in trecherus soil in city streets where traffic interferes, the dist the mat'l must be transported may be from a few feet to several miles, the difference in elev'n may be plus or minus a hundred ft or more, the depth of cut may be a few inches or beyond the reach of the machine, and any one or more of a number of kinds and sizes of conveying devices may be employd.

9.913. The C E with wide experience in excavating and conveying may usually be able to estimate unit costs with a tolerable degree of accuracy, by merely looking at the work to be done, and reviewing the machines available.

9.914. It seems best, however, in addition to referring to what figures we can in sec 9.92 with their wide discrepancies, to expect the less experienst C E to figure out each problem for himself as nearly as may be, from the figures we have given in the preceding sections, of capacities, weights, speeds, etc, of the machines available, subject to careful judgment based on what we have said regarding utility of each device. The computations usually involv nothing more than simple arithmetic, but it is essential that all factors or elements be considerd. To this end, we give in sec 9.94 a list of such items as *may* enter into any given problem, tho some or many of them may amount to zero in any particular case. See sec 9.95 for an example.

9.92. Cost Data

9.921. For suggestions in **this book**, see as follows;—

Pages 1024 *et seq*, for comparativly **primitiv** methods of excavation and transportation, noting that figures are based on labor at $1 per 10-hr day.

Pages 1105-7 incl, paragrafs 53-56 incl. These figures are for **railroad** work, practically all for 1914 and earlier.

Page 1408, para 2.11. From **Bidding Estimates.** Years of 1925-6.

Pages 581*w* and *x*, paragrafs 138-153 incl. Figures apply to **dredging** only, 1914 and earlier.

9.922. On the Welland Canal (1922-1931 only) **rock** excavation and disposal cost on an av $6.27/cu yd under water, and $2.12 on dry land.

9.923. A review of "Current Construction Unit Prices" as estimated by bidders, in recent issues of Eng News-Rec, may disclose figures that may be of servis, and that will require no adjustment for time, altho of course there is nothing to indicate how far the actual cost came from the amts bid.

9.93. Coefficients

Tables and charts frequently found in engineering periodicals may be of great use "*provided the conditions are those for which the chart* (or table) *is made*", or if proper coefficients may be applied to the result to adjust to the actual conditions. We offer the following suggestions.

9.931. Coeffs for different **Years.** In Eng & Contr'g, '28 Aug, p 416, is a table and diagram showing yearly av prices of **common excavation** on the Wabash RR from **1899 to 1915** incl, from which may be computed a coeff for changing the cost of any one of these years to any other.

From "Eng News-Rec Construction Costs", publisht annually by McGraw-Hill Pub Co, New York, N Y, may be obtaind comparativ costs of many factors entering into C E work, from **1913** in most cases, **to date.** At least, the curv for **common labor** may be of servis in adjusting data betw such dates.

9.932. Output Coefficients following are abstracted from "Output Factors for Excavation and Material Handling Equipment", by A. E. Holcolm, in Civil Eng'g, '30 Oct.

9.9321. The factor is 1.00 when the operating conditions are reasonably favorable, the dipper shovel or drag-line bucket has a capacity of 1 cu yd, an 8 ft cut is being made in ord'y earth, and the av swing of the boom is 90°. **Note** that these are *not cost* coeffs such as in sec 9.931, and that the two are not nec'y reciprocal of each other.

For **Materials,***

Hard shale and other rocky formations poorly blasted	0.40
Fairly well blasted rock or hard-pan, and tough rubbery clay	0.50
Clay and boulders	0.60
Heavy clay (not sticky)	0.70
Clay gravel	0.80
Wet sandy clay	0.90
Ordinary earth	1.00
Light dry loam or clay, loose sand and gravel, cinders and ashes	1.10
Light moist clay and loam	1.25

Size of Shovel Dipper or **Size of Drag-line Bucket;** is directly proportional to output. Thus, a half cu yd dipper will take out only half as much as a 1 cu yd dipper in a given time.

Output coeffs for **Depth of Cut** for a **Shovel** swinging 4 revs/min, and other conditions as above (9.9321), which should excavate about 100 cu yds/hr,

Depth of cut, ft	1	4	8	12	16
Coefficient	0.62	0.89	1.00	0.88	0.76

Output coeffs for **Depth** of end-cut excavation by **Drag-Line** with conditions as in sec 9.9321, which should excavate 80 cu yds/hr;

Depth of cut, ft	1	4	8	16	24	32	40
Coefficient	0.82	0.95	1.00	0.90	0.80	0.70	0.60

9.9322. Example. A ¾ cu yd shovel, working in clay gravel, with a cut of 12 ft, may be expected to produce abt

$$\underset{\textit{cu yds/hr}}{100} \times \underset{\textit{dipper coeff}}{0.75} \times \underset{\textit{mat'l coeff}}{0.80} \times \underset{\textit{cut coeff}}{0.88} = \underset{\textit{cu yds/hr}}{52.8}$$

* Cost coeffs establisht by A T Cushing, Eng News-Rec, '26 Sep 9, applying esp'y to **trench** work, agree fairly well with Mr Holcomb's figures, when the reciprocals are used.

9.94. Cost Elements

to be considerd when computing output or costs.

9.941. Major Elements. (a) Excavation, (b) Transportation, (c) Backfilling or Spreading.

9.942. Working Rates for computation of volume excavated and transported per time, should include time for (1) Loading, (2) Transporting, (3) Unloading, (4) Returning, and also for (5) Idleness due to weather, repairs and lack of co-ordination.

9.943. General. Camp Maint, Supt and Eng'g, Maint of Roads, Profit, Effect of Size of Job.

9.944. Machines. In any case, Power, Labor, Repairs, Maintenance (oil, etc). If rented, cost of Rental, if ownd, Interest and Depreciation, and Idle Time.

9.95. Example

To illustrate the way in which the above suggestions under sec 9.94 may be used, we give the following comparativly simple example, in which all quantities are entirely **fictitius**, and are not to be taken in any way as figures for estimating. Our computations are carried to not more than 3 or 4 significant figures, because it is impossible to compute such results to within a few percent.

Given:—20,000 cu yds of earth to move an av dist of 1000′, and that it can be dumpt on a spoil bank without spreading. Suppose we have a 2½ cu yd gasoline shovel capable of digging 300 cu yds/hr, and that we can hire all the 5 cu yd trucks we need, capable of 15 mi/hr loaded, and 20 mi/hr unloaded over the territory involvd.

At 300 cu yds/hr, our **shovel** should finish, theoretically, in 20,000/300 = 66 hrs, or, allowing 25% lost time, in 83 hrs. Using sec 9.944 as a reminder, we might have, $2/hr for gasoline, $1/hr for labor, $2.50/hr for repairs and maintenance, and $2.50/hr for int and depreciation, or a tot of $8.00/hr, which, for 83 hrs would cost $664. To this we should perhaps add interest for 15 days since the last job, say $50, and $50 for moving from it to the present location, making tot cost for shovel, **$764.**

Taking up the items in sec 9.942, as applied to the **trucks,** and considering loading first, we allow two shovel cycles of 30 secs each for loading, plus 15 secs to "spot" under the shovel and to pull out, or 75 secs. To travel 1000′ at 15 mi/hr (= 22 ft/sec), will require theoretically 45 secs, or say 50 secs, allowing 5 secs for accel and decel. For dumping we allow 10 secs. For the return, at 20 mi/hr, 33 + 5 = 38 secs. Tot, 173 secs for each truck load of 5 cu yds. As there are 20,000 cu yds to move, we shall need 4000 truck loads, or, at 173 secs/load, 692,000 secs. The shovel, however, needs only 83 hrs or 298,800 secs. We shall need then, 692,000/298,800 = 2.31 trucks, theoretically, or 3 actually. This excess of truckage should allow suff time for item (5) under sec 1.942, (idleness due to repairs) altho serving the shovel with only two trucks, for a time, may perhaps more than help to use up the 25% allowd for delays to it. (Delay due to weather we take up later). Considering sec 9.944, we assume for each truck $1/hr for gasoline, $1/hr for labor, 25c/hr for repairs and maintenance, totaling $2.25/hr. This, multiplied by 3 × 83 = 249 truck-hours, givs $560. In addition we must allow say $15/day for rental of each of three trucks for 83 hrs or 10½ days, plus 4 days allowance for bad weather, (tho it may

rain for weeks at a time or not at all) or 14½ days, totaling $652. This, with the $560 above for operating, totals **$1212.**

General expenses. Considering now sec 9.943, we allow 25c/hr for office overhead (rental, etc); superintendence, $1.25/hr; total $1.50/hr. Allowing for 100 hrs to include office work outside the machine time, this, with $25 for surveying, totals $175. We assume no special road maintenance, but allow for 3 helpers for 10½ days at 50c/hr each, totaling $126. For general expense, then, we allow $175 + $126 = **$301.**

Totals. Adding totals for shovel, trucks and general expenses, we have $2277. Allowing 10% for profit, this becomes **$2505**, the total for the job. Dividing by 20,000 cu yds, we obtain 12.52c/cu yd. Bear in mind that this example is entirely fictitius, for purely imaginary conditions, to illustrate the kind of method that may be used.

DREDGING

References. Those contributing most largely have been;— W L Saunders, XII International Congress of Navigation; A W Robinson, Am Soc C E, Vol LIV, Part C, and numerus others writing in Eng News, Eng Rec, etc, and F Lester Simon's book "Dredging Engineering".

1. Excavating, in general, is the work of loosening and moving materials, such as earth, rock, etc. It is called "dredging" when water overlies the mat'l to be moved. In many instances, the methods or devices employd may be the same or similar, whether the work goes on above or below water.

2. Usually the **object** of moving the material is to **increase the depth** of the waterway, to accommodate vessels of greater draft. Sometimes, however, the object is primarily to obtain gold or other **precius metals** from the dredged material, or to **raise the level of land**, by heaping dredged material on it. If it is desired both to dredge and to raise the land level at places near each other, the two operations may often be combined.

CONTROLLING FACTORS

3. Methods of dredging, and the devices used, depend chiefly upon the character of the material to be excavated, which may vary from silt to solid rock. However, there are often other considerations of much importance.

Materials

4. Mud, Silt and Sand are generally the easiest materials to excavate, but the means used to dislodge them, may so mingle them with the water, that they may be carried away by the water to some other place where they are equally unwelcome, or other mat'l may drift in and refill the excavations, necessitating repetition of the work. Or, it may become necessary to handle disproportionately large quantities of water with the mat'l, making subsequent separation very troublesome.

5. Loam, Clay. These, and the gravels, are ordinarily easy to dredge, altho sticky clays are likely to give trouble by adhering to the buckets after they have been excavated. When they are handled by hydr dredges, they may stick or jam in the suction orifices or pipe-line.

6. Indurated Clays or Hardpans may be so hard as to be quite difficult to dredge, and it may even be expedient or necessary to blast them.

7. Disintegrated Rock, Boulders, Rock. Solid rock, must, of course, be broken up before it can be removed. The fragments so obtaind, may still be too large to be handled by the machinery employd, and may have to be broken to a still smaller size. In disposing of the dredged rock, it is often desirable to provide additional apparatus for sorting out the varying sizes, which may be wanted for different purposes, or for separating the rock from soil that may be mixt with it.

8. Gold and Other Precius Metals are usually found mixt with gravel or small boulders. See ¶80 and immediately before.

9. Additional apparatus, tailings stackers, gold-saving tables, etc, not strictly dredging machinery, will be needed to separate the metal from the gravel, and where rock may be utilized, still more apparatus may be required for sorting, as in ¶7.

10. Debris may include almost anything except fairly uniform ground. It may be ground containing old stumps of trees, often making necessary more than one kind of dredging apparatus to complete the work. Under this head would come also wrecks of all kinds, from wreckt masonry (sea walls, bridges, etc) to wreckt ships. Dredging machinery may be useful also in removing piles or other structures in water

11. Coral formations are usually quite difficult to handle, and often require much previus blasting

Operating Space

12. The type of dredge to be used is determind largely by the character of the space in which it is to work. In the open, work may be delayd by **rough water or storms,** for few dredges can weather storms well, and the several units of a plant may become damaged by pounding against each other In channels, the rapidity of the **current** may make it impracticable to hold in place and operate certain kinds of dredges. In channels, anchoring becomes troublesome, as the cables, or the pipe-lines of hydraulic dredges, are likely to interfere with passing ships, or, in very narrow channels, the **passing ships** may disturb the dredge by creating suction on one side **Confined spaces** around docks, etc, may make it impracticable to employ certain types of dredges.

Character of Work

13. The Depth and Width of cut required may determin the type of dredge. Care must be taken in considering the proposed depth of dredging, to allow for the **"squatting"** of vessels, that is, the increast draft due to their motion, an item that is different for each vessel Tho squat becomes noticeable only in large craft moving at high speed, yet it has produced an increase in draft of as much as 4 ft. (Simon, "Dredging Engineering").

14. The Distance the dredged mat'l must be transported is a very important consideration, often calling for much auxiliary equipment, such as scows, and tugs to handle them, or long pipe lines. Sometimes the mat'l must be rehandled at some intermediate point.

15. The Permanence of the work also controls very largely **New work, or isolated** bits of work, with completion in sight, may justify the use of almost any dredge available that can do the work, even tho very poorly suited to it. For **maintenance** work, however, or where there is prospect of repetitions of the same kind of work nearby, the tendency should be to obtain machines closely adapted to the work in hand, and with high operating efficiencies.

16. Much may depend, also, upon whether **other kinds of work** are to be done that can be combined with the dredging, such as land filling, obtaining sand, road materials, etc, since one type of dredge might be much better adapted to such combination than another which might be ideal for one kind only.

17. Government or Public operation, more common in foren countries, makes possible and economical the employment of much larger and more elaborate dredges than are possible under private control, and has been the chief reason for certain diffs in types of dredge used here and abroad.

18. Time, also, may enter into the problem, for if there is not time to obtain the ideal dredge, or, if the work must be done very rapidly, it may be necessary to employ dredges that will do the work uneconomically.

Operating Facilities Available

19. The Kind of Power available will sometimes influence the selection of the type of machine to be used Conversely, the mech'l equipment of an available dredge, may determin the kind of power to be used. See ¶114.

20. The Crew available may also be a controlling factor, both as regards their number and experience on the particular type of dredge contemplated for the work

21. Supplies. The availability of fuel, repair facilities, new or duplicate parts, as well as food, shelter, etc, may all largely determin the choice of a dredge type, since one dredge, otherwise well suited to the work in hand, may be grossly lacking in such facilities, while another, by its superior equipment, may promis better, even tho not otherwise the appropriate machine for the work

DREDGES *

and Dredging Devices

Classification

22. Means for dredging may be classified broadly as follows;—

Training walls, reaction jetties, etc
Drag-line or scoop dredges
Cableway excavators
Bucket or grapple† dredges
  Clam-shell dredges
  Orange-peel dredges
Dipper dredges
Ladder, or continuus bucket dredges
Hydraulic dredges
Rock dredging
  Rock breakers
  Rock cutters
  Blasting
"Universal" and miscellaneus dredges.

Training Devices

23. Walls, dikes, partial dams, etc, may be used under certain favorable conditions, to create or maintain deep water, by causing currents to operate in such ways as to increas depth by scour; but their treatment is reservd for another place.

Drag-line or Scoop Dredges

24. General Features. Fig 1. The boiler and engin *E* used for the work, are mounted together on a frame, or platform, and may be housd in. From the front of the platform there extends a long boom *B*, held up by an adjustable guy or stay *G*, which bears on an A-frame *A*, and is fastend at the back of the platform Connected to the engin drum is a cable which extends to the end of the boom, and then downward over a pulley, as shown at *H*, to the rear of a bucket or **scraper** *S*. At the front of the scraper is a harness or bail, to which is fastend a second cable, or **drag-line** *D*, also manipulated by the engin. The entire outfit is mounted on a turn-table which is itself mounted on a truck of some kind. The turntable is usually able to swing thru an entire hor circle, in either direction. The truck is usually fitted with either (a) wheels which run on temporary tracks; (b) skids bearing on rollers, or (c) a "caterpillar" gear.

---

* Called "dredgers" in Great Britain.
† This word is used by some to denote a bucket specially designd for picking up bulky objects, as stones, logs, etc.

25. Operation. The scraper S is lowerd by means of the cable H, to the bottom. The cable D is then tightend, and the lip of the scraper thus forst into the mat'l, which it scrapes up and collects within itself. When the scraper is full, the cables are so adjusted that it is raisd from the bottom still maintaining its nearly level position Then, if the mat'l cannot be dumpt betw the digging position and the machine itself, the entire apparatus is swung to a position such as that shown by the dotted lines, so that the mat'l may be dumpt where it will be least in the way. D is then relaxt, and the scraper drops, open end down, thus dumping its contents The machine is then swung back for another cut.

26. Sizes and Capacities. The following figs are approx av extremes of regular construction

Boom, 40′ to 150′ long
Bucket capacity, 1 to 5 cu yds.
Digging depth, side cut, 15′ to 50′, end cut, 20′ to 70′.
Weight, 75,000 lbs to 550,000 lbs.

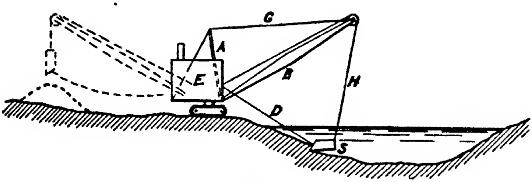

Fig. 1.

27. Utility. The use of drag-line scoops under water is rather recent, but seems to have been very satisfactory so far as tried The scoop, not being mounted on a vessel, must do all its work by reaching out from land, and the dist beyond shore to which it can excavate is necessarily limited by its reach, whereas dredges bilt as parts of vessels can go as far from shore as their seaworthiness will permit. The chief use of the scoop as a dredge, therefore, is for deepening comparativly narrow channels, such as canals and irrigation ditches. Owing to the almost direct hor pull, and negligible vert pull on the end of the boom, when digging, and the resulting small overturning moment, the machine is capable of distinctly difficult work, such as rooting out snags, boulders, stumps, etc.

28. Cableways, or Tower Excavators are used sometimes insted of derricks, for handling scoops, and also for handling grapple buckets But if a revolving derrick is available, even if it must be shifted across the stream to complete its work, it will usually be found preferable to the cableway with its two cumbersome towers If the derrick cannot reach far enough, either a cableway or a dredge becomes necessary, and of course there are limits to the economical span of a cableway.

Grapple* Dredges

The Dredge.

29. The dredge itself (see also Scows, etc, ¶111), Figs 2(a) and (b), consists of a vessel V, which carries the necessary machinery DD' are two hoisting drums operated by steam or gasoline engins or electric motors. Over these pass two wire hoisting cables, known as the "closing" and "opening" lines, H and H', which are gided by sheavs CC' on an A-frame A, and thence pass over sheavs on the end of the boom B, and down to the bucket K. Other apparatus, not here shown, and to be described later (¶46, etc) must be provided for holding the dredge in place, and for holding to the side of the dredge the scow which is to receiv the dredged mat'l

* The word "grapple" is sometimes confined to special forms of grab buckets designd for handling bulky objects, as stone, logs, etc.

30. The Vessel or Hull *V* is usually rectangular, since such a form affords a max of stability to resist the moments set up by digging and by swinging the boom over the scow. There is seldom need for a hull designd for easy navigation. It must be very substantially constructed, and braced by suitable trusses, bulkheds and knees. There is bilt on the vessel, also, such **housing,** *E*, for machinery and men, as may seem desirable.

31. The Boiler and Engin, or motors, are of the usual types, Scotch marine, or other boiler: 2-cyl hor engins, driving standard hoisting machinery. (See Mechanical Enginer's Hand-Books). The boiler (or power-line, if electric) should be of sufficient capacity to operate all the aux'y engins simultaneusly if need be, and the hoisting engin should be of ample size to withstand hard usage See under "Power", ¶114, etc

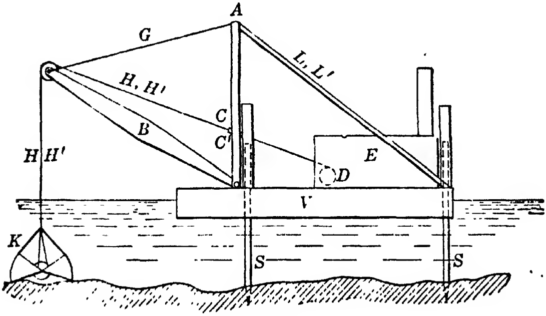

Fig. 2 (a)

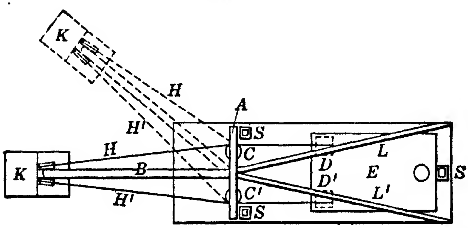

Fig. 2 (b)

32. The A-frame, as its name implies (tho not obvius from the figs, since it is there viewd edgewise) is shaped like a letter "A". The element corresponding to the hor portion of the letter is generally referd to as **"the table".** At or near the table are mounted two sheavs *CC'* which hold apart the hoisting wires. The A-frame is held in position at its top by **back-guys or back-legs,** or both, *LL'*.

33. The Boom, *B*, is usually maintaind at a fixt vert angle by means of a guy-wire or "topping-lift" *G*, but is arranged to rotate on a pivot at its lower end thru a considerable hor angle. The upper end of the boom carries the two main sheavs over which pass the bucket-hoisting lines.

34. The Bucket.

35. The Grab, Grapple or Bucket is mfd in two types, the **"clam-shell"** or **"crab"**, Fig 7, having two segments or shells, and the **"orange-peel"**, Fig 8, having three or four segments.

36. The Principle on which the two kinds of buckets operate is similar, and is perhaps best explaind by first assuming a hypothetical clam-shell bucket, Figs 3 (*a*) and (*b*) and then explaining the modifications necessary Each shell, *S* or *S'*, consists of a curvd plate, forming about a quarter of a circumf, and of two side sectors or flat cheek plates. Thus, Fig 3 (*a*), the two shells, when closed, form a semi-cylindrical bucket, open at the top The shells are pivoted together at *C* by pins or hinges, and if supported by a sufficiently large force at *C*, the bucket would retain material *M* within it. But provision is made, thru the rods *OP* and *OP'*, for applying upward forces at *P* and *P'*, so that on reducing *C* practically to zero, the bucket must collaps at the middle, as shown in Fig 3 (*b*), forming a wide opening under it, thru which the mat'l falls If now the bucket is lowerd upon loose mat'l, and the forces again be reverst, the two shells will not only reshape themselvs into a bucket, but will gather up a certain amount of any loose mat'l on which they rest.

37. At *O* is attacht one of two wire ropes, known as the **"opening line"**, while at *C* is attacht a second rope or cable, known as the **"closing line"**. It is thus possible, with only two lines or ropes, not only to raise and lower the bucket as a whole by hauling up or lowering on both lines simultaneusly, but also to open or close the bucket, by paying out or reeling in one line with relation to the other

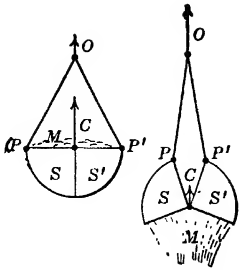
38. Actually, the bucket shown in Fig 3 will gather up but little of any hard material, since not enough of the lifting force *C* can exert closing or biting forces.

39. Practical Design. To overcome this, the bucket closing forces are increast. In one make of bucket, a simple **lever** *L*, Fig 4, is made a part of one of the shells *S* The closing line passes down around a pulley on the end of the lever, and returns to a point near *O*, where it is made fast The force *C* must therefore exert a closing force greater in relation to the lifting force, than in the case assumed above in Fig 3 Other pulleys may be provided near *O* and at *C*, and the line led back and forth until suff closing force, for a given lifting force, is secured

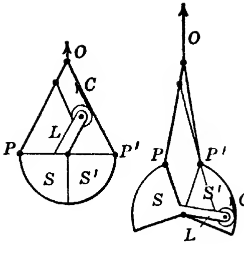
40. A "Drum and Shaft" arrangement, however, is more generally provided, as in Fig 5. The "drum" indicated by the large circle at the center is little more than a large pulley. Around it is wrapt and attacht the end of the "**closing** line" *C* (or *H* Fig 7). The "shaft", indicated by the smaller circle, **consists** in reality of a pair of small drums, one on each side of the large pulley, and around them are wrapt and fastend two branches of chain *Z*, the other ends of which are attacht to the frame at *O* The force *C* thus sets up in *Z* a much greater force than itself, and an increast closing couple is set up by *Z*, pulling up at the shaft, and exerting at *O* a downward thrust equal to *Z*, carried out to *P* and *P'*; this without increasing the lifting force (approx $=C$) on the bucket as a whole

41. Yet such design would mean serius fouling of the shaft and drum by the contents of the bucket. In practis, therefore, the shaft and drum are mounted much higher, somewhat as shown in Fig 6 (*a*), the bucket shells having heavy arms or extensions. See also Figs 7 and 8.

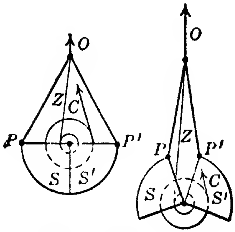
42. Bucket Details. Figs 7 and 8 are outline sketches of the clam-shel and orange-peel buckets respectivly, shown open ready for grabbing a load Since all dredging devices must work in dirt which necessarily increases the wear, all **pivots and bearings** should be made with bushings than can redily be removed and renewd. "The **cutting edge or lip** of each shell is generally strengthend by the addition of a steel casting, or, preferably manganese steel, the better to resist the severe abrasion". (Simon, Dredging Engineering). **Teeth** may be attacht, but they are often used mistakenly,



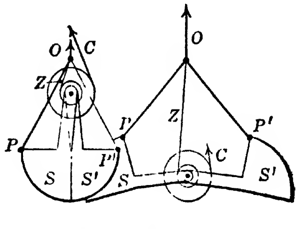
(a) Fig. 3 (b)



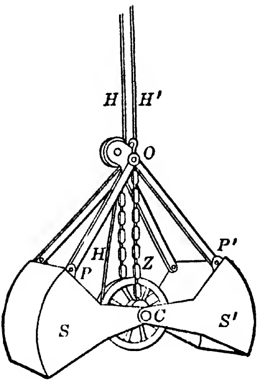
(a) Fig. 4 (b)



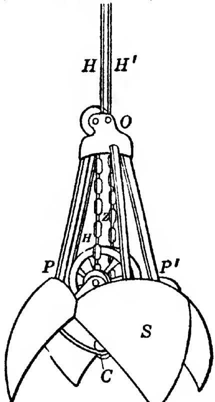
(a) Fig. 5 (b)



(a) Fig. 6 (b)



"Clam-Shell"
Fig. 7



"Orange Peel"
Fig. 8

and are seldom of use on large buckets "Teeth are of no advantage in handling coal, sand, gravel, crusht stone, or other bulk material of a granular lumpy kind" (Blaw Bucket Manual).

43. On account of the twist of the strands of the hoisting cables, and because there is practically no force to prevent the rotation of the bucket about a vert axis (which would make the hoisting wires bind on each other), it is usally necessary to provide some means to prevent such twisting A **"dorsey wire"** may be used, which is simply a light line, one end of which is attacht to the side of the bucket nearest the dredge, while the other is past over a pulley or sheav about midlength of the boom, with a weight attacht, just heavy enough to prevent such twisting, but in no way interfering wth the other motions. Another device consists of two long **uprights** attacht rigidly to the two sides of the bucket, which extend up thru gides provided at the end of the boom, thru which they slide vert'y These uprights have the additional advantage of holding the bucket vert in case it is lowerd on an uneven bottom.

44 In France for dredging in clay, the bucket is sometimes lined with wood, to which the clay less readily adheres,

45. Other Types of buckets have been bilt, one like a pair of tongs, and another in which the closing force is supplied by comprest air **Single-line buckets** are bilt, requiring only one hoisting line They usually depend upon some arrangement of latches or catches Where only a single hoisting line is available, such an arrangement is essential; but none of those mfd seem to be sufficiently satisfactory in their operation to take the place of the two-wire arrangement where that can be had.

Moorings.

46. Perhaps the simplest and cheapest method of fixing the position of the dredge and of holding to it the scow which is to receiv the dredged mat'l, is that of using **wire ropes,** which are controld by aux'y engins thru capstans or drums on the dredge, and which are made fast to nearby objects, or to anchors or especially driven piles On at least one dredging operation (in Galops Rapids, St. Lawrence R, Report by W. L Saunders, XIIth International Congress of Navigation), where the current was very violent, **chains** were used insted of wire ropes See ¶104. The use of lines for holding the dredge is generally unsatisfactory when many other vessels must pass the dredge.

47. Spuds *SS*, Fig 2, are therefore often employd Many dredges are equipt both with spuds and mooring lines, thus affording greater flexibility of operation. The spuds are simply large uprights, of timber or steel, arranged to move vert'y in wells in the dredge or in pockets on the sides. Usually there are three or four spuds. Two of them are rigged near the front of the dredge, and are maintaind upright by means of a gallows frame spanning the entire beam of the vessel, (usually near the A-frame, and sometimes combined with it); while the rear spud or spuds are held alongside rigid or guyd posts, or else pass vert'y thru other framing. Usually the spuds merely rest upon the bottom, being prevented from floating up by hevy metal pointed shoes, which also aid in penetrating the bottom, and in protecting the ends of the spuds. They are raisd or lowerd, usually by means of cables, sometimes by racks and gears, operated by special engins on the dredge The spud cables are sometimes past over sheavs at the tops of the spuds, or other means are used for forcing the spuds down, sometimes to the extent of lifting the dredge slightly from its normal floating level, thus making it quite rigid; but more usually the vessel is free to ride up and down on the spuds, which serve merely to maintain the desired lateral position.

48. To Shift the Position of the dredge when spuds are used, the bucket may be gript into the bottom, and all the spuds raisd but one of the forward two. Then, by a pull on the proper bucket line, the dredge may be rotated about the one spud as a pivot. Then the two front spuds are made to exchang functions, and the dredge is advanst still further by pulling on the other line. The process is well referd to as **"walking on the spuds".** See also "walking", "fleeting" or "trailing spuds," ¶64.

49. Sometimes the spuds are utilized to keep the mooring cables below the keels of passing vessels. In this case, sheavs are provided at the bottoms of the spuds, around and under which the mooring cables are past, the spuds acting only as brackets, and the cables doing the work of maintaining the position of the dredge. (Patented by Osgood Dredge Co)

50. Dredges bilt for drainage ditches sometimes employ **"bank spuds"**, which reach out at a vert angle from the dredge, and penetrate the bank or rest in grillages set in the bank. These afford great lateral stability.

51. In some cases (where the bank cannot be reacht) **side floats** have been provided, which greatly increas the lat'l stability These may be essential if the dredge is of narrow beam.

52. Where the dredge can do all of its work from the bank, it may be mounted like the drag-line scrapers, (¶24), the **caterpillar** mounting being now (1925) generally preferd.

Operation.

53. After the dredge is made fast, a scow (¶111) is brought up along one side, and made fast If on the right side, as is usual, then the "closing line" is the right-hand or starbord line H, Fig 12 (b), while the "opening line" is the left or port line H' The "table" sheavs CC keep these lines so deflected that as the tensions in them are altered, th boom swings hor'y. Thus, after the bucket has been lowerd to the bottom, tension is put on the closing line, which therefore (1) closes the bucket upon its load, (2) hoists the load, and, at the same time (3) swings the boom over to the right. When the boom comes over the scow, the tensions in the lines are reverst, with the result that (4) the bucket is opend and dumps its load into the scow, and (5) the boom is swung back to its digging position Both lines are then slackt off, and the bucket so lowerd The position of the boom can be nicely controld by an experienst operator, by reversing and adjusting the stresses in the two wires at the proper instants.

54. The curv of the bucket shells should not be such as to fit well into their own bite, since it is likely that a suction may be establisht in soft mat'l which may be very hard to break Attempts to use a light bucket not designd for hard biting, will soon result in injury to it. If teeth are added, they may only bend the lips of the shels, and if the operator tries to make a light bucket bite by dropping it violently on to the mat'l, the bucket will soon be injured The remedy is either a hevier bucket, or means for exerting greater closing forces, or both.

Sizes and Capacities.

55. Some very large dredges have been bilt, one recently (1921) advertised having a bucket cap of 30 cu yds, the bucket alone weighing 40,000 lbs. The bucket capacities more usually range from a fraction of a cu yd up to 7 or 8 or 10 cu yds, with wts from 4000 to 26,000 lbs. On machines in quantity for the market, the booms are generally under 50 ft long, but machines are constructed with booms from 100 to 200 ft long or longer.

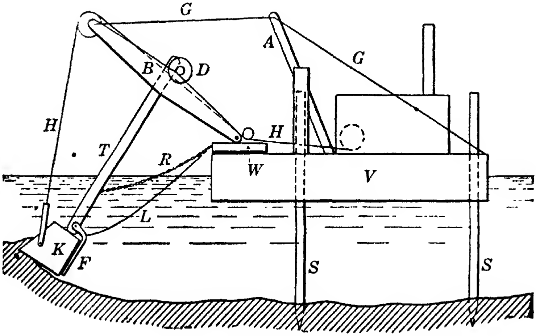
Utility.

56. In suitable mat'l (as sand, clay or mud), the grapple dredge is very efficient The **depth** to which it is able to dig is theoretically limited only by the length of cable which can be wound on the hoisting drums; but with increast depth, the bucket cannot be counted on to settle on just that part of the bottom desired The bottom made by a grapple dredge is usually uneven, with holes and high spots A grapple dredge is generally not good for very hard digging, unless the masses to be grappled with are broken. The dredge is useful around docks and in narrow channels, tho it cannot well be used where there is no room for the scow to be maneuverd alongside. The **clam-shell** is most useful in soft mat'l, stiff mud and sand (when not too fine), gravel, coal, ore, and small disconnected masses of rock of from ½ to 4 or 5 tons. The **orange-peel** seems especially adapted, in spite of considerable uncertainty of grasping when far under water, to the dredging of boulders, blasted ledge rock, pig iron, stumps and the like—the roots of stumps being cut thru on all sides by the 3 or 4 shells with their 6 or 8 cutting edges; also for excavating within caissons in foundation work.

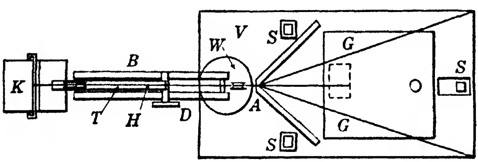
Dipper Dredges

The Dredge.

57. The dipper dredge, Figs 9(*a*) and (*b*), consists of a vessel *V*, much the same as that of the grapple dredge, ¶30, tho even more strongly constructed, and carrying the necessary machinery. The vessel is almost invariably equipt with spuds *SS*, the forward ones being sometimes held by a frame (not shown) spanning the width of the vessel There is also an "A"-frame *A*, tho not necessarily with the hor "table", and this frame is often inclined, as shown Over it pass guy wires *GG* which hold up the end of the boom *B* and maintain it at a fixt angle. The foot of the boom, however, is placed at the bow and is so arranged that the boom may be swung hor'y The boom is so constructed that another member, called the "stick" or "dipper handle" *T* can pass thru it To the lower end of the stick is attacht the bucket *K*, which has a flap-bottom door *F* engaged by a latch (not shown).



(*a*)



(*b*)

Fig. 9.

58. **Boilers and Engins,** or electric or gasoline motors, are provided for the varius operations described below and also for handling spuds and other auxiliaries. The **hoisting line, main line or bucket wire** *H* passes from the drum of the main engin under a sheav at the foot of the boom, thence to a sheav on the outer end of the boom, and from there down to the bucket bale. Usually the line passes under another sheav on the bucket bale and

back up to the end of the boom, where it is made fast. There may be also a **backing chain** *R* with its engin or motor (not shown). In many cases there is a **"crowding engin"** or motor *D* (shown only diagrammatically), mounted on the boom where the stick passes thru, by means of which the stick may be forst to rise or fall.

59. It is well to have the hoisting line wound on a **"differential" drum,** conically shaped, and having helical groovs, so that during the first part of the pull, when the resistance due to separating the load from the bottom is greatest, the line is wound on the small part of the drum, affording the engin a max of leverage, whereas, when more line is wound on the drum, it lies on portions of larger diam, and so makes possible higher hoisting speed when the resistance is less.

60. The Boom *B* of a dipper dredge, must be exceptionally strong and well designd It consists usually of girders, deepest at the center, the better to resist the bending moments It is usually made in two halvs, with a space betw, thru which the stick (see ¶61) may operate, tho in some cases the stick is divided and straddles the boom In operation, and especially where a crowding engin is used, the direct bending stresses set up at the middle of the boom may be quite large In addition, the rotation of the boom may be effected by an engin driving a **bull-wheel** *W* at its heel, and this will set up twisting stresses which may be quite serius in case the lateral movement of the dipper is arrested abruptly by striking the bottom or other object

61. The Stick *T*, as stated, passes thru the boom *B*, and is handled by the lines *H* and *R* Usually it carries a rack which engages with gears and wheels at *D* Not only can the stick move longit'y, but it can rotate about the pinion at *D* In some cases these wheels are provided with brakes only, and in others they are part of the "crowding engin", which can aid in the movements by forcing the stick up or down In gen'l, the motion produced is similar to that of a man digging with a hand shovel.

62. The Bucket *K* carries a cutting lip at its outer end, usually bearing individual detachable steel spikes or **"teeth"** where hard mat'l is encounterd. It is rigidly attacht to the end of the boom Its bottom consists entirely of a **flap or trap-door** *F* hinged at the rear. A latch is provided for holding the flap closed, and a line *L* passes from the latch back to the enginman who may thus open the flap The flap is so counter-weighted as to caus it to hang at about 45°, and the impact of striking the water, in its descent, is counted on for closing it.

63. The Digging Operation, then, consists in releasing the hoisting line *H* and the clutches or crowding engin at *D*, thus permitting the bucket to descend (the flap being closed by the water surface) while the backing chain *R* is pulled so as to draw the bucket to the rear. When the bucket reaches the bottom, the clutches at *D* are closed, and the hoisting engin is operated, with the result that the bucket makes a cut along the bottom. The hoisting is continued (clutches releast) and the bucket is hauld out of the water. The boom is swung hor'y either by two operating lines as is customary with grapple dredges, or by means of a bull-wheel *W* at the base of the boom, until the bucket is over a scow which has been brought up alongside, or over a bank or other available point at which it may be desired to deposit the mat'l. The latch is then drawn, the flap opens, and the contents drop out If the mat'l sticks badly in the bucket, the operator may use his crowding engin to jerk the stick back and forth (while in nearly hor position) thus slapping the flap violently against the bottom edges of the sides, and helping to jar the mat'l loose. The boom is then swung back, and another cut is started, as above.

Moorings.

64. For dipper dredges, moorings may be substantially the same as for grapple dredges, except that mooring lines are rarely if ever used, and the **forward spuds are especially strong** to resist the high and erratic digging stresses. The rear spud stands in a slotted well to provide motion fore and aft, and is called the **"walking", "fleeting" or "trailing spud".**

65. To Shift the Position of the dredge, the bucket is lowerd on to the bottom, the forward spuds are releast, and then the backing chain is pulled; the dredge moving ahead and the rear spud tilting in its slotted well. The forward spuds are then set down again, and the rear spud raisd and advanst for the next "step".

66. Scows may be Handled by the dipper, the spuds remaining down, and the dipper resting on the scow and moving it about by means of the bull-wheel and crowding engin, or hoisting and backing lines.

Sizes, Capacities, etc.

67. The bucket capacities generally used are from 1 to 5 cu yds Larger sizes are not unusual, while the famus dipper dredges of the Panama Canal had a cap of 15 cu yds in mud or 10 in rock The following figures will afford a fair idea of the extremes.

Hull		
Length, ft	144	40
Width, ft	44	18
Depth, ft	13½	4½
Draft, ft	8	
Digging depth, ft	50	9
Dipper capacity, cu yds	15	¾

68. Speed. In medium sized machines, the dipper can make one cut in from about ½ to 1 min during steady working (not allowing for waits for scows, repairs, etc)

69. Utility. On account of its ability to maneuver itself and its scows without lines, the dipper dredge is especially useful in confined spaces, around docks, and in narrow channels By its ability to force the bucket into the bottom, it is especially capable in hard mat'ls, for the removal of boulders or rock that has been broken up (as by blasting), and for tearing out miscellaneus obstructions, as piles, old cribs, wrecks or foundations. It can "cut its own flotation" ahed of it, thus digging a new channel where none existed. On account of the poor leverage, however, it is not available for as great depths as the grapple or hydr dredges but it can level off the bottom very much more accurately than the grapple dredge.

Continuus Bucket, Elevator or Ladder Dredges

70. Three Types of "ladder" or continuus bucket dredge are in gen'l use, referd to as (1) the **"Stationary"**, (2) the **"Barge Loading"**, and (3) **"Sea-going Hopper"** dredge.

71. The Vessel or Hull is different for each of these The "stationary" dredge has a hull similar to those of the grapple and dipper dredges; but the other two (2) and (3), are bilt with molded hulls to minimize resistance, and are equipt with propelling engins The "barge-loading" dredge (2) depends upon barges or scows to receiv the mat'l it excavates, while the "sea-going" dredge, (3), Fig 10, is bilt with self-containd hoppers *HH*, since it is intended for use in open waters, where there would be serius pounding of any aux'y craft alongside.

71½. A notch or elongated well *W* is formd down thru the bow or near the middle of the vessel to receiv the "ladder" *L* and the chain of buckets *BBB*, tho in some "stationary" dredges, two ladders are employd, one on each side, outside the hull.

72. "The Ladder" *L* is a long frame, pivoted at its upper end *P*, while the lower end is held at the desired elev'n by a line *N* operated by a winch *C*. At each end of the ladder is a large tumbler or drum, and rollers are provided along the upper side of the ladder.

73. The Buckets *BBB* are carried on an endless chain over the drums and rollers, hanging freely from the under side. The chain of buckets is operated by a special engin or motor (only the main wheel *E* of which is shown) engaging with the shaft of the upper drum. Each bucket is provided with a reinforst cutting lip, or with teeth.

74. Operation. As may be seen, each bucket, in turn, cuts some mat'l from the bottom. Then, as the bucket revolvs, the mat'l is caught up, and is then carried to the top of the ladder, where it is dumpt out as the bucket turns over The bucket then descends (inverted) back along the lower side of the ladder As the cutting progresses, the dredge is advanst by its own engins, or is swung as in ¶77.

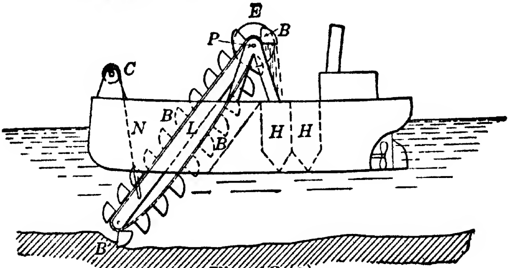


Fig. 10 (a)

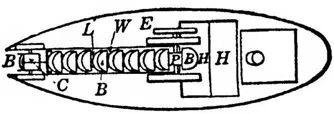

Fig. 10 (b)

75. The Disposal of the Material is different in diff types of dredges, and again, with diff kinds of mat'ls. In the sta'y barge-loading dredge, suitable chutes are provided to pass the mat'l over the edge of the vessel into a scow made fast at the side (Where ladders are placed on each side of the vessel, the mat'l may fall directly into the scows). In the hopper dredge, Fig 10, the mat'l is dropt into the hoppers *H*, and the dredge travels to a suitable dumping ground, where the bottoms of the hoppers are opend and the mat'l is deposited. When desirable to separate diff kinds of mat'l, as in digging for gold, or where the bottom consists of rock and finer mat'l to be sorted, rotary screens or separating devices of one kind or another are introduced betw the top of the ladder and the chutes or hoppers. These, not being strictly dredging devices, are not treated here. In some cases, the mat'l can be conveyd hydraulically thru long pipes, as in hydr dredging (see ¶89, etc) insted of depending upon scows. (Simon, "Dredging Engineering").

76. The Engins or Motors for such dredges may be of any suitable type, but on account of the complete balancing of the moving parts, and the relativly stedy cutting forces, except when encountering markt irregularities of the bottom, and the nearly uniform loads to be lifted, steam engins may be operated expansivly if the bottom is soft and uniform, while these conditions invite also the use of electric and possibly gasoline motors.

77. Moorings. The so-called "stationary" dredges are usually held in place by means of a half dozen lines, operated by winches on the vessel, several lines or a rear spud controlling the advance of the vessel, while several other lines cause the dredge to swing from side to side with a radial movement as the cutting progresses.

Sizes, Capacities, etc.

78. The following figures are intended to give approx values of the usual extremes or averages.

Hull, length, ft	130* to 275*;
width, ft	36 to 56,
depth, ft,	15 to 20+.
Draft, ft,	up to 12
Digging depth, ft,	30 to 60.
Buckets,	
cap each, cu ft,	5 to 50; number on ladder, 42 to 70;
speed, ft/min,	45 to 80; number per min, 10 to 30

Hopper capacity (sea-going), tons, 500* to 2200*
Digging capacity, cu yds per day, 8000 to 28,000.
Speed of vessel (sea-going), mi/hr, 6 to 8 or 10.

Utility.

79. If **Sand and Gravel** are not too fine, the continuus bucket dredge can handle them well; also rather hard mat'ls, as indurated **clays, shales,** and even **soft or broken rock** and hard-pan, especially where the depth is too great for a dipper It can cut its own flotation It is especially valuable where the disturbance of the bottom would be serius On this account, perhaps, its greatest use in this country is in:

80. Gold Dredging. Neither grapple nor dipper dredges can clean the bed rocks next which gold is usually found, and either will permit the dredged mat'l to leak serusly thru the cracks in the bottom, while hydr dredges cannot create suff suction to gather up the heavy gold along with the sand. The continuus delivery of the "ladder" dredge lends itself also to the smooth and continuus operation of separating devices Gold digging operations are usually sufficiently extensiv to warrant the large investment needed.

Hydraulic Dredges

81. Two main Types of hydr or suction dredge may be recognized, (**A**) Figs 11(*a*) and (*b*), that in which the dredged mat'l is disposed of by means of a hydr pipe-line, constituting a dredge of the "stationary" type, usually designated as a "pipe-line" dredge, and sometimes as a dredge of the "river type" (Simon's "Dredging Engineering"), or (**B**), ¶93, the dredge may be of the "sea-going hopper" type

(A). "Stationary", Pipe-line or River type Dredge.

82. The vessel or hull *V* Figs 11, is of the common rectangular form, (housing not shown), but it need not be so strong as other kinds of dredges, for there are practically no digging stresses, except those produced by the cutter, ¶86.

83. The dredging machinery consists of a suction pipe *S*, Figs 11, mounted on a "ladder"* At the lower end of the suction pipe and ladder is usually a "cutter" *C*, ¶96, which servs to break up the mat'l to be dredged. The dredged mat'l and accompanying water are drawn up thru the suction pipe by means of a centrifugal pump *P*, which creates the suction and sends the accumulation thru a delivery or discharge pipe-line, *D*.

84. The "ladder"† The upper end of the ladder is pivoted at the front of the dredge, while the lower end is held at the desired elevation by means of a line *L* passing over an inclined A-frame *A*, which is back-guyd by other frames and wires *W*.

85. The suction pipe *S* usually lies within the ladder, and at its upper end, at *F*, is provided with ball-and-socket joint, which connects it with the pipe leading to the pump *P*, thus permitting vert, and in some cases, hor movement.

---

* From Simon's "Dredging Engineering."

† Tho such ladders are unlike those familiarly known, yet the name "ladder," for this arm or boom, seems to be entirely usual. Care should be taken, also, not to confuse this with the so-called "ladder" dredges, which we have usually referd to as "continuus bucket" dredges.

86. The cutter *C*, Fig 11(*c*), is often used on "stationary" dredges It is generally of approx barrel, conical or paraboloidal form, and consists of an aggregation of cutting edges or blades. In clayey ground, the mat'l is likely to stick and clog the cutter unless the openings betw the blades are ample The cutter is mounted on a shaft coincident with its axis, and the shaft is usually just above the opening of the suction pipe *S*, and extends back along the ladder *L* to the gears which connect it with its engin (see end of this paragraf). The diam of the cutter is about twice that of the pipe. As the cutter is rotated, its lower half, extending somewhat below the end

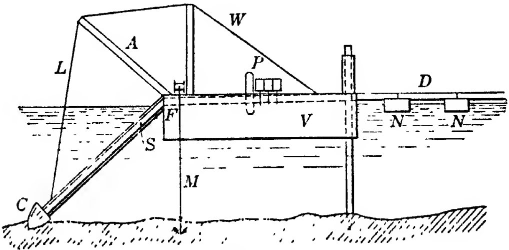

Fig. 11 (a)

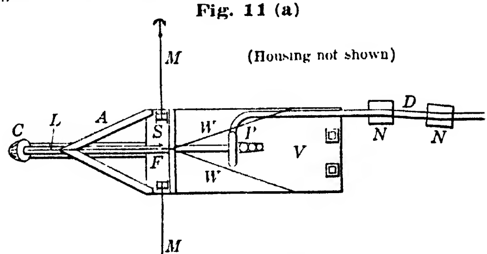

Fig. 11 (b)

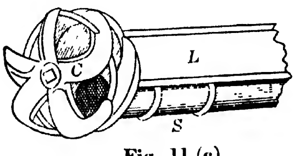

Fig. 11 (c)

of the suction pipe, cuts out the ground. The ground, along with suff'y large quantities of water, is then suckt in thru the cutter, and on into the suction pipe *S*. Where long objects, as pieces of trees or piles, may be encounterd, there is danger of damage, for as the object works its way thru the cutter and into the pipe, it comes in position to be sheard off Insted, however, some part of the machinery may be broken, unless the parts are amply strong to stall the engin. Screens are frequently inserted, either on the

rear of the cutter itself, or at the outer end of the suction-pipe The **engin** or motor for driving the cutter is of course mounted far enough back on the boom to be out of water, or it may be on the dredge itself and operate thru gears.

87. The Pump *P* is invariably of the centrifugal type, as nothing else will handle the dirt and rocks and other objects that may have to be dredged. The rotating impellor is usually of the "closed" type, *i e*, with face plates on the inner sides, which can redily be renewd, and can take the wear that would otherwise come on the pump casing itself. Some claim that the impellor blades may slope either forward or backward, (Trans Am Soc C E, 1904, LIV, Part C, p 505), or that the inner half of each alternate blade may be cut out entirely (Eng N-R, '20 Jul 22, pp 166–170) in order to permit of the free passage of large bodies, as rocks and stumps, without greatly reducing the effic'y of the pump While there has been much discussion on this point, ideally high efficiency of the pump while running may perhaps well be considerably sacrificed, if, by so doing, we can greatly reduce the time lost standing idle due to clogging and break-downs

88. The Engin is usually triple-expansion condensing. Electric motors are coming largely into use.

89. The Discharge Pipe-line *D*, Figs 11(*a*) and (*b*), is usually laid along the dredge to the rear, making as few turns as possible. It is well to provide a check-valv or other device, to prevent flooding the vessel in case of breakage of the pipe In any case, this pipe should be exceptionally strong From the rear, it is carried over the water on floating **pontoons** *NN* of some available type, placed at intervals, while flexible joints of one form or another are provided, suff to permit a considerable amount of wave action vert'y, and movement of the vessel laterally and fore-and-aft This section of pipe need not have so high a factor of safety. The pipe terminates where the dredged mat'l may be disposed of Provision must be made for **impounding** the mat'l, so that the solids will settle and remain in place while the water flows off. Where the discharge line must be so long as to result in inefficient operation of the pump on the vessel, one or more "booster" or "relay" pumps may be inserted in the pipe-line.

90. Maneuvering. (1) The vessel may be held rigidly in position by spuds, ¶47, while the lower end of the suction pipe is swung hor'y over the bottom about a pivot at its upper end The vessel is then advanst, preferably by means of a "walking spud", ¶64, at the rear, while the two forward spuds are raisd; after which the swing of the suction is repeated (2) Usually, the ladder is fixt, and two spuds *SS* are provided at the rear, as shown in Fig. 11 (*b*), so spaced that by lifting and letting down first one and then the other, the dredge may be swung as a whole from side to side by means of mooring lines *MM*, at the same time advancing suff'y for the next cut.

91. Operation of hydr dredges is comparativly simple, practically all movements, etc, being under the control of only one man The eff'y, however, depends chiefly upon his skilful handling. If the suction pipe is not fed into the cut rapidly enough, power will be wasted in pumping water with too little solid mat'l. If, on the other hand, too great a cut is attempted, or if the cutter-head is not appropriate to the work, or if water-jets (¶94) are used too sparingly, clogging may result, either at the entrance, or, more seriusly, in the delivery pipe. The action cannot, of course, be seen by the operator, but he learns of conditions thru the indications of pres and vac gages connected with the suction and delivery pipes, and by the behavior of the cutter. The delivery pipe, if long, and if terminating on land, necessitating continual attention for shifting, may require a larger crew than the dredge itself.

92. Utility. The hydr dredge is largely and effectivly used in handling sand, silt, mud and clays, in open water, on ocean bars, and in channel maint, as in cleaning out old canals, and as used on the Mississippi R To some extent, gravel and small stones may be dredged with the aid of a cutter, and, with a large machine, even stumps, large rocks and other debris may be removed directly, tho large stumps may have to be undermined and then lifted out in some other way. The pipe-line and mooring lines may offer considerable obstruction to navigation.

(B). Sea-going Hopper Dredge.

93. This dredge is similar in many ways to the pipe-line dredge. The following diffs may be noted.

94. The Vessel of this dredge is bilt with molded hull, and contains its own marine propelling engins The dredging machinery is similar, but the **orifis or "drag-head"** at the lower end of the suction pipe is usually flared laterally to form a long slot, open part down, sometimes with one edge extended to act as a cutting edge or scoop, and may be from 5 to 20 ft long and approx 1 ft wide This orifis, placed at rt-angles to the length of the vessel, drags over the bottom as the vessel moves along, acting much like a household vacuum cleaner, except that water insted of air is the medium for carrying the dirt, and the dirt is subsequently separated by sedimentation insted of being filtered out **Water jets** are often used at the orifis, arranged so as to break up the mat'l to be excavated, and to put it into better condition for being suckt up. **No ladder** is used, the pipe being its own arm. If one pipe is used, a **well** is cut thru the hold, but it is usual to employ **two pipes, one on each side** of the vessel, outside the hull. The **pump and engin** are much the same as in the pipe-line dredge, except that where two pipes are used, the centrif pump may be a double one, with the advantage of balanst hydr thrusts. **No discharge pipe line** is used, the water and dredged mat'l being deliverd into **hoppers** bilt into the hull, as in the continuus bucket sea-going hopper dredge, ¶¶ 71 and 75, provision being made for draining off the water **Maneuvering** consists merely in steaming along slowly while the lower ends or drag-heads of the suction pipes drag over the bottom, and the movements are repeated, in approx paralel courses, as may be nec'y. **Operation,** so far as control of suction and cutting are concernd, is much the same as with the pipe-line dredge (¶82). **Utility.** The advantages are, freedom in navigation, no exceptional obstruction to other vessels, sea-going ability, and lack of pipe-line. The chief disadvantage lies in the necessity for stopping when the hoppers are full, and traveling to a suitable dumping ground and returning.

Sizes, Capacities, etc.

95. Where two figures are given, they are for usual min and max; while three figs denote usual min, av and max respectivly.

	"Stationary"	General	"Sea-going hopper"
Hull, length, ft	70 – 200		140 – 460
width, ft	20 – 44		30 – 50
Digging depth, ft		15 – 50	
Ladders, length, ft		45 – 85	
Pump, pipe diam, ins		12, 20, 48	
runners, diam, ins		46 – 96	
Vel in pipe line, ft/sec		10 – 18	
Pumping cap, cu yds/day		5,000 – 50,000*	
% of solids pumpt		5*, 25*, 40	
Horse-power		up to 5000	
Hopper cap, cu yds			300 – 3000†
Speed of vessel, mi/hr			6 – 10
Cost of dredge		$100,000 – $400,000	

Sub-Aqueus Rock Excavation

Methods

96. Where rock is loose or quite soft, it may be dredged directly, as by dipper or continuus bucket dredges. But where it is hard, it must first be broken, either by rock-breaking machines or by blasting, and then dredged.

* Dredges "Delta" and "J. Israel Tarte".

† From Simon's "Dredging Engineering".

Rock Breaking, Hammering, Cutting or Chiseling Machines.

97. The Lobnitz type of breaker is similar to a pile-driver, and consists of a barge carrying machinery for operating a massiv steel ram, which is repeatedly raisd and dropt on to the rock beneath, which is thus shatterd more or less. The ram is from 30 to 60 ft long, and up to 2 ft or more in diam. Together with the special shoe on its lower end, it may weigh from 3 to 18 or 20 tons or more, tho the lighter rams are now seldom used, and rams of over 15 tons are exceptional. The ram is dropt thru a lft of from 3 to 15 ft, depending largely upon the results obtaind, and at frequencies of from 2 to 18 drops per min, 4 to 12 being usual. The rock may shatter to a depth of from 1 to 6 ft, depending upon its nature. Authorities do not recommend that rock-breakers attempt to break up a layer more than 2 ft thick at one time, tho operations are frequently forst down thru 3 ft. (For greater depths of excavation, rather than stop, dredge and break again over the same area, drilling and blasting is recommended and usually resorted to). After shattering the rock at one point, the barge is shifted from 3 to 5 ft either ahead or laterally, and the operation is repeated, attacking the rock on the corners of a checker-bord pattern. Usually, 10 to 30 blows suffice at each point, tho some rocks have yielded under 2, while others have required over 50 blows. The resulting rock-breakage may amount to from 150 to 300 or more cu yds per day (of 24 hrs). The life of the point of the ram may be from 100,000 to 500,000 blows, and is lengthened by having the point hardened at its core, so that as the ram wears, it will always remain fairly sharp.

98. The Submarine Co has patented a rock-cutter in which the ram is surrounded by a metal casing, extending down to the rock surface, from which the **water is kept expeld** by comprest air, and the point or chisel is separate from the body of the hammer, and remains upon the rock. It is claimd that the resistance which water offers to an exposed ram is so serius as to make this machine exceptionally effectiv.

99. Care must be taken to prevent the cable to which the ram is attacht, from slacking down after the ram strikes bottom, as the cable is likely to kink, and to be injured or to break when again puld taut.

100. If the bottom slopes much and is very hard, rock breakers are difficult to operate, for the ram receivs a severe hor reaction, and the mounting and barge are seriusly rackt if the lateral movement is restraind.

Blasting.

101. Unconfined Explosivs, merely laid on the surf of the rocks and there exploded, have been used with some success on soft rocks. A second charge over the same spot may do fairly efficient work, but the resulting debris acts as a cushion for any further charges, and should be cleard away before proceeding.

102. Drilling and Blasting is the usual method of breaking rock under water. **A barge or scow** is used, 80 to 130 ft long, 30 to 45 ft wide, and 7 or 8 ft deep, with a draft of about 4 ft. It must be solidly bilt to withstand the shocks of the blasts. Usually it has a strong **spud** at each corner, operated by power, so that the barge may be lifted from its normal flotation, thus practically standing on the bottom.

103. Some half dozen **drills** may be mounted on the barge, with a **spacing** of 6 or 8 ft, being either of the usual "drop" or "percussion" type, but exceptionally massiv and powerful, and delivering abt 250 strokes per min. While the mountings of the drills do not seem to have been standardized, yet in gen'l the drills are mounted on **towers or colums,** and either over-reach the side of the vessel or operate down thru wells. Provision is made for raising and lowering the drills either by sliding on the towers, or by mounting each drill on a colum or **"drill spud",** which can be raisd or lowerd as a whole, while alongside the colum are carried long gide pipes or tubes, inside which the drill operates. The pipes and drill spud extend down to the rock, and serv to stedy the drill rod, to relocate the hole when changing drills, and to reduce the inflow of soft mat'l. The towers, colums, or drill spuds, are usually so arranged that they can be moved laterally, to adjust their spacing as desired. The **bits** are from 2½ to 3½ ins in diam, 3″ or more being more usual. The **depth** of hole is abt equal to the spacing betw holes, but should eventually extend sev'l ft below the level to be attaind, to allow for irregular breakage.

104. Blasting is accomplisht by 60 to 75% dynamite, in sticks 2 to 2½ ins diam, tampt in place from the drill boat. *The drill boat is then moved* abt 50 ft away, and the charge exploded electrically. The boat is then returnd and starts a new row of holes a dist ahead abt equal to the lat'l spacing employd. One of the most notable pieces of work was that done in the **Galops Rapids** of the St Lawrence R, with a turbulent current of 8 to 12 mi/hr. The drill boat carried four 5″ drills. It was held in place by four 20″ x 20″ power-controld spuds, with the aid of five 1¼″ chains which were used also for maneuvering, and which, on account of their wt and sag, prevented the development of sudden severe stresses. 75,000 cu yds of rock were excavated; av cut 6.5 ft; 1 1/3 lbs of 75% dynamite per cu yd. The blasted rock was removed by a dipper dredge, similarly equipt with spuds and chains

105. Undermining, Mining, or Honeycombing, has been employd here and there in large operations, such as the removal of Flood Rock, East R, New York The area to be excavated is first enclosed, as by cofferdams and pumpt out (unless part of the rock is above water level, when the work may be started from dry rock), after which shafts and drifts and tunnels are drild and blasted out, and then loaded with dynamite and prepared for electric firing The area may then be flooded and blasted, often in a single blast

105½. Diving Bells have been used occasionally on small operations.

Dredging.

106. After breaking up the rock by any of the methods given above, it must be removed Dipper or continuous bucket dredges are usually employd for this work, as in ¶¶ 57 etc and 70 etc.

Miscellaneous Dredges

107. "Universal" or Combination dredges have sometimes been used, consisting merely of several kinds of dredging machines assembled together on the same vessel, and are prob seldom advisable unless there is in prospect an unusually large amount of work for which such a combination would be of servis

108. "Hydraulic Giants" may sometimes be employd to advantage to break down a bank in advance of the regular dredge on which they may be mounted A hydr giant consists of a large nozzle which may be aimd as desird, and supplied with water at very high pres thru piping, by means of a powerful centrifugal pump.

109. Pneumatic dredges have been tried, but apparently without success.

110. A "Stone Lifter" was used by the Canadian Gov't on the St. Lawrence R, consisting of a grab with tongs, operating thru a well in the center of the vessel, being capable of lifting boulders of 50 tons each. (Prelini, "Dredges and Dredging")

TRANSPORTATION OF MATERIALS

Scows or Barges

111. The vessels used for carrying the material from the dredge should be very strong, to withstand the shocks of loads of dirt dumpt into them, and probable rough treatment in maneuvering They are usually merely rectangular barges Within, however, are false sloping sides, which lead the mat'l down to the hoppers in the center of the bottom, and which, together with the vert outside walls of the vessel, form an air space which supplies most of the buoyancy. The hopper doors, when opend, should not extend below the bottom of the scow, as they may strike ground. They are usually operated by chains working over winches on frame-work above. The scows, if they are to carry economical loads, may be of considerably greater draft than that of the dredge, so that it is sometimes necessary to maintain a channel of extra depth, in advance, to accommodate them.

112. Different Materials may make trouble for scows in varius ways. Sand and silt, deposited from a hydr suction dredge, may not settle rapidly enough, and much may be lost overboard with the water. Clay often sticks when the hoppers are opend, and may have to be washt out. Gravel

gives perhaps the least trouble of any. Large rocks, of course, even when deposited carefully, hammer the scows seriusly, and shorten their lives.

113. Chutes, Shoots or Slides of varius kinds are often employd as means toward final disposal. Wet clay will slide on a chute inclined at 1-on-5 to 1-on-3; but wet sand will not move on 1-on-2 without water or pushing; and the usual slope is 1-on-1.5 to 1-on-2.2, or 1-on-1.8 to 1-on-2. However, Prelini, in his "Dredges and Dredging", quotes from 1-on-10 for soft mud, to 1-on-25 for fine sand and water, perhaps with ample lubrication by water.

POWER

114. Steam is the most usual power for dredges, tho apparently unable to give anything like continuus servis. Steam dredges are customarily shut down for a day each week on the Mississippi or other rivers where the water is bad. A condensing plant and extra boiler may be necessary.

115. Oil engins are coming into considerably greater use. They have from 2 to 6 cyls, with H-P around 100. The use of **friction clutches** is important to prevent stalling or injury by unexpected overloads. Drag-line excavators on the drainage works of the Rio Grande irrigation project (Eng N-R, '19 Sep 18) operated with fuel costs of from $0.011 to $0.022 per cu yd of mat'l excavated.

116. Electricity, where readily available, is claimd to have many advantages;—lower first cost, no boilers on dredge (making smaller hull possible) no coal to transport, control simple and good, and more nearly continuus operation than steam. Tho practis is not definitly crystalized, it is customary to carry the current from the land to the dredge at 2200 volts, by means of a **cable** designd for much higher voltage to protect it against abrasion, etc. Sometimes the cable is laid in the water on the bottom, but often it is carried over the water on pontoons, utilizing the pontoons of the discharge pipe if there is one; or the cable may be floated by buoyant sheathing. Where there may be lightning, thoro protection against it is advisable. The **motors** are either 2200-volt, operating directly from the cable, or if of less voltage, a transformer is instald on the dredge. Motors are used of from 50 to 800 HP or more, and run from abt 1100 to 360 revs/min.

SURVEYS AND COMPUTATIONS *

117. Ordinarily, a cross-section of a body of water to be dredged, will correspond broadly to Fig 12, in which *NFABEM* is the bottom. Usually all that will be needed for passage of vessels will be an enlarged cross-section such as *ABCD*. (See also ¶13 in regard to "squatting".) But if the approx triangles *FAD* and *BEC* are not excavated also, they may sooner or later fall into the area *ABCD*, and reduce its depth. These **side slopes,** *FD* and *EC*, will range from 1-on-3 to 1-on-5; under docks, 1-on-2 to 1-on-4; while river silt may flow out almost flat. Furthermore, it is impossible for any kind of dredge to excavate to precisely the plane *FDCE* desired, but must excavate somewhat below it to insure that all mat'l above has been removed. This will result in a somewhat irregular bottom, as *NfghijklmM*, which should be nowhere above *FDCE*. Inasmuch as an operator might prefer to dig out large chunks to much greater depths than called for, so as to be paid for this excessiv removal of mat'l, it is customary to specify a still lower level, *NLGM*, a given vert dist below the reqd depth *FDCE*. This is known as **"overdepth"**, and only that mat'l is to be paid for which lay above the irregular line *Nfghi*, the *straight* line *ik*, the irregular curv *klm*, and the straight line *mM*, is to be paid for; *ik* and *mM* illustrating instances in which the overdepth was exceeded in the actual dredging. The overdepth is usually taken as 2 ft for grapple and dipper dredges, and as 1 ft for continuus bucket and hydr dredges.

118. Soundings are made usually both before and after the dredging, and in front of and to the rear of the dredge, as it proceeds, by any of the usual methods. Thus, there is establisht the topografy of (1) the original bottom, represented by *NFABEM*, in the section shown in Fig 12, and (2) the excavated bottom, represented by the irregular line *NfghijklmM*. The soundings taken in advance show whether the depths are suff for flotation

* Nearly all of the information in this portion of this article, ¶¶117 to 131, has been deduced from Mr. F. Lester Simon's "Dredging Engineering".

of the scows. Owing to the great cost of **rock** excavation, surveys for it should be made with exceptional care, and **wire sweeps** should be employd after excavating, to make sure that no points remain above grade.

Place Measurement

119. Computations of volume excavated betw the irregular surfs represented by *NFABEM* and *NfghijklmM*, may be made by any one or more of the following methods **Averaging end areas** is largely used for long narrow areas, as channels The **Prismoidal formula,** as employd in RR earth work computations, is also used. In the **contour-planimeter** method, contours are plotted from the soundings obtaind, and a planimeter traced over them in order to obtain the areas, and from these the vols, assuming that the vol is composed of flat slabs with thicknesses equal to the vert intervals betw contours, and with vert edges co-inciding with the contours. Either this or the following is well adapted to large irregular areas **Square section or "unit"** method, in which the vol excavated is conceivd as composed of vert square prisms, each prism containing one sounding, or a group of soundings.

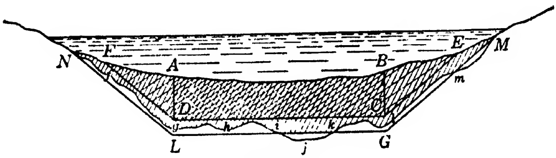

Fig. 12.

119a. Uncertainty in place measurements may arise becaus mat'l from districts outside the dredged area may drift back in while the work is going on, thus giving the contractor more mat'l to excavate than would be indicated by the two place measurements. Prelini ("Dredges and Dredging") believs this never exceeds 10% of the entire amount excavated. On the other hand, the new excavated channel, if appropriately located, may result in a scour which would help the contractor. For such reasons scow measurements are usually made where practicable, in addition to the place measurements.

Scow Measurement

119b. By Volume. For this purpose, the internal vol of the scow (or hoppers, on sea-going dredges) is ascertaind, and if the mat'l is at any time piled up above the upper level of the scow, the vol of such pile must be computed or closely estimated (say by cross-sectioning, as in RR work).

119c. By Weight. Or, by computing the external vol of the scow, its displacements may be ascertaind for given supposed added loads, so that by measuring the amount by which the scow is deprest by the added load of excavated mat'l, the wt of that mat'l can be found, (provided the water density can be made sure of, which may not be practicable in tidal estuaries). It would still remain, however, to translate the wt into vol, which can of course be done by weighing and measuring the contents of an evenly filled dipper, for example.

120. Uncertainty due to Increas in Bulk will still exist, however, becaus practically all mat'ls, after being excavated, will not settle back into as small a space as they occupied "*in situ*", and the increas in bulk is by no means the same for all mat'ls. The increas to be allowd should be establisht in the contract. It may usually be taken as betw 5 and 30%, tho usually betw 15 and 25. For a heavy mixture of mud and sand, it may be taken as 16 or 17% (an increas of 1/6), fine running sand or silt, less than this, and mud or clay more when stiff enough to hold its voids. Prelini

("Dredges and Dredging") states that in the Ambrose channel, New York harbor, the increas was found to be 22%, and recommends that 30% be allowd

120a. Probings or Borings may be desirable or necessary, to ascertain in advance the character of the mat'l to be excavated. **Probings** consist in the driving of pointed rods into the bottom, and so "feeling" the character of the mat'l. **Borings** may be either core or wash borings, and aim to bring reliable samples of the mat'l to the surf *Core* borings may be obtaind either by driving an open pipe into the bottom and then removing it with the mat'l adhering inside, or by means of a wood auger operating within the pipe Or a larger pipe may be first driven into the bottom, pumpt out, and then a smaller pipe forst down inside and then removed, thus obtaining samples nearly dry and undisturbd *Wash* borings are usually made by operating a hollow drill within a pipe, water being forst down thru the hole in the drill, with the result that at least the lighter portions of the borings of the drill are washt up to the surf, but the results are likely to be misleading

Miscellaneus

121. Range targets will be needed (unless the channel is quite narrow) to guide the dredge on its proper course Range targets are usually establisht and maintaind by the engineers of the party employing the dredge The **locations** of the targets should be laid out on the map Where possible, the targets should be on the shore, or maintaind on piles specially driven, since anchord targets can hardly be held near enough to correct positions. Each range is indicated by two targets, one a considerable dist behind and at a slightly higher elevation than the other; and for each range a diff character of target should be employd, as square, round, oblong, triangular, etc, while further diffs can be had by varying the colors If the dredge is to work at night, lights must be used at the targets The **directions** of the ranges should usually be paralel to the current, as this gives the greatest ease in placing and holding the dredge where desired The **width of cut** for diff dredges is given as follows

Grapple,	50 to 60 ft,	Hydraulic,		40 to 50 ft,
Dipper,	20 to 60 ft,	"	stern spud pivot,	150 to 200 ft

122. Tide Gages will be needed, unless the depth of water remains pract'y constant to enable the operator to adjust the depth of cut, as the stage changes, and should be set up and painted boldly, so that he can see them readily.

123. Current Drift may have to be determind to assist in proper location of a channel, or for other reasons, and may be ascertaind by any of the usual float methods.

Records.

124. Maps should of course be prepared, showing the soundings, and kept up to date, to show progress of the work

125. Material Removed by Scows or Hoppers (except for hydr pipeline dredges), and other information that may promis to be of value, should be recorded.

126. Time records should be kept of all operations, and subsequently classified or "distributed" in order to learn where wastes occur, and to otherwise supervise and adjust the methods of working (See ¶154 etc, Percentages of time spent in dredging operations)

127. Cost Estimates. See also ¶135 The elements that may be needed for estimating cost of work are summarized below from Simon's "Dredging Engineering". (Certain items would obviusly not arise on certain kinds of work.)

128. *Preliminary Engineering* Engineers and assistants and their equipment, on all steps from making surveys, to contracts, borings; overhed.

129. *Permits, Property.*

130. *Preliminary Structures* Dikes, ditches, shore pipe-lines, construction plant, transportation, field office, overhed.

131. *Dredging proper.* The engineer need concern himself with the following only when he is operating the dredge himself. Plant, labor, supplies, dump maint, and engineering and overhed connected with this work.

OPERATION AND MAINTENANCE

Operating Efficiency

132. Dredges are usually so seriusly subject to breakdowns, and the entire plant is so very expensiv, that operating efficiency while running, is usually of much less importance than **continuity of operation.** Refined machinery of high theoretical efficiency is likely to prove much less efficient in the long run, than hardy machinery that may consume more power continuusly or need more men, but which does not involv frequent shut-downs covering long periods. For this reason also

133. Duplicate Parts are strongly urged by almost all authorities. The depreciation of such parts is slight, but that, together with the interest on the investment, is likely to be far less than the cost resulting from trying to work without such parts on hand Not only is there the computable loss of time, but the delays are demoralizing to the crew, especially if men are laid off.

134. Good Management is of prime importance. Fuel must be supplied in ample time to avoid shut-downs The boilers should not be fed with water of doubtful character A clean and ship-shape dredge has a good effect upon the crew The large suction dredges of Toronto harbor (Eng Rec '16 Apr 15) have main floors of cement and composition rubber, and a min of wood trim. The tendency to run a dredge somehow, as long as possible, should be replaced by a strong policy of maintaining it continuusly at the best possible

COSTS

135. Satisfactory dredging costs are seldom available Figures often appear to refute each other. Often one or more of the following pieces of information is omitted,— type of dredge, mat'l handled, whether interest and depreciation are included, time idle, number of shifts, etc.

136. Modifying Factors. After referring to the data given below, estimates should be made of the probable or possible effects of the following,— dist to point of deposit, weather conditions, exposure of site, depth of cut, time idle, collisions and other accidents, the general skill of those operating, and efficiency of the machinery See ¶¶ 3 to 21

137. All figures are to be taken as applying **before the War of 1914.**

Classified by Dredges

138. Drag-line Scrapers. Silt, loam and hard-pan from abt 12 to 20 ¢ cu yd, while disintegrated rock may run the cost up to 45

139. Grapple dredges, (including clam-shell and orange-peel). Mud, sand and clay from abt 8 to 60 ¢ cu yd, more usually 15 to 40.

140. Dipper dredges Light mat'ls, as mud, sand, silt, gravel and clay, at from 8 to 40 or 60 ¢ cu yd, tho hard-pan may run the cost up considerably over $1 00.

141. Continuus Bucket dredges Mud, silt, clay and disintegrated rock, from 10 to 30 ¢ cu yd.

142. Hydraulic Pipe-line dredges ("stationary"). Nearly everything but rock, from 5 to 30 ¢, cu yd.

143. Hydraulic Sea-going dredges Mud, silt, sand and gravel, often as low as 2 or 3 ¢/cu yd, with maxima around 10, tho one record gives 36.

144. Rock Breakers or Cutters. Figures appear very uncertain. From 25 and 30 to 70 or 80 ¢/cu yd are usual, but these figs seem to be for breaking only. One figure* is $9/cu yd. Dredging would be extra.

145. Drilling and Blasting has been recorded as low as 18¢/cu yd for breaking only, while figs around 50 ¢ to $1 are usual. However, in Black Rock Harbor, Buffalo (report by W. L Saunders, in XIIth Internat'l Congress of Navigation), the tot cost including depreciation (but not dredging) was 48 ¢/cu yd with drill holes av'g 9'9" deep, while with holes only 3'6" deep, the cost ran up to $5.57/cu yd. Again* $6.13 is quoted. One figure is available including dredging, $1.55¢/cu yd.

---

* British Columbia dredging fleet, Eng Rec '13 Aug 23, p 209. Not stated whether dredging is included.

146. Undermining and Blasting of Flood Rock cost something under $3/cu yd for breaking only; and $5.88 including dredging.

Classified by Materials

147. Mud is generally removed at from 2 to 10 ¢/cu yd, tho the cost is occasionally considerably higher—around 30 or 40 if the job is small.

148. Silt usually around 7 ¢/cu yd.

149. Sand; min around 5 ¢/cu yd, with 10 to 15 or 20 as more usual figures, occasionally running up to 30 and 40 or more for small jobs

150. Clay is seldom excavated as cheaply as 5 ¢/cu yd; more usually 10, 20, 30 and 40.

151. Hard-pan and Disintegrated Rock from 20 to 40 ¢ or 50 ¢/cu yd —possibly a dollar or more.

152. Gravel, 2 to 12 ¢/cu yd, or possibly as high as 30

153. Rock, see ¶¶ 144 etc, Rock Breakers, etc

Percentages of Time
Spent in Dredging Operations

154. The following figures have been compiled from Report of Chief of Engrs, U.S.A., 1919, being av's of a number of diff dredges of each type, and are especially valuable as indicating the ways in which serius losses of time may occur.

155. Time at Work	Bucket	Dipper	Hydraulic Pipe-Line	Sea-Going Hopper
Dredging	10 15	5 88	15 12	14 35
Waiting on tug	0 30			
Handling scows		0 37		
Handling pipe-line			1 94	
Handling swinging wires			0 98	
Turning in cut				0 79
To and from dump				7 16
Dumping				1.39
Spudding up	0 30	0.38		
To & from wharf & anchor'g			0 27	2 49
Placing dredge			0 57	
Taking fuel and supplies				2 99
Waiting for vessels to pass			0.18	
Miscellaneus	1.67	1.63		
Totals, time at work	12.42	8 26	19 06	29.17

156. Time Lost from Work	Bucket	Dipper	Hydraulic Pipe-Line	Sea-Going Hopper
Repairing	4.60	2.58	7.70	11.01
Bad Weather	1.90	5.44	2.41	3.29
Changing location of plant	2.97	1.21	2.58	0.00

FOUNDATIONS.

A VOLUME might be occupied by this important subject alone. We have space for only a few general hints; leaving it to the student to determine how far they may be applicable in any given case. In ordinary cases, as in culverts, retaining walls, &c, if excavations, or wells, &c, in the vicinity, have not already proved that the soil is reliable to a considerable depth, it will usually be a sufficient precaution, after having dug and levelled off the foundation pits or trenches to a depth of 3 to 5 ft. to test it by an iron rod, or a pump-auger; or to sink holes, in a few spots, to the depth of 4 to 8 ft farther; (depending upon the weight of the intended structure;) to ascertain if the soil continues firm to that distance. If it does, there will rarely be any risk in proceeding at once with the masonry; because a stratum of firm soil, from 4 to 6 ft thick, will be safe for almost any ordinary structure; even though it should be underlaid by a much softer stratum. If, however, the firm upper stratum is exposed to running water, as in the case of a bridge-pier in a river, care must be taken to preserve it from gradually washing away; or from becoming loosened and broken up by violent freshets; especially if they bring down heavy masses of ice, trees, and other floating matter. These are sometimes arrested by piers, and accumulate so as to form dams extending to the bottom of the stream; thus creating an increase of velocity, and of scouring action, that is very dangerous to the stability both of the bottom and of the structure. When the testing has to be made to a considerable depth, it may be necessary to drive down a tube of either wrought or cast iron, to prevent the soil from falling into the unfinished hole. If necessary, this tube may be in short lengths, connected by screw joints, for convenience of driving, and the earth inside of it may be removed by a small scoop with a long handle.*

Borings in common soils or clay may be made 100 feet deep in a day or two by a common wood auger $1\frac{1}{2}$ inches diameter, turned by two to four men with 3 feet levers. This will bring up sample-

In starting the masonry, the largest stones should of course be placed at the bottom of the pit, so as to equalize the pressure as much as possible; and care should be taken to bed them solidly in the soil, so as to have no rocking tendency. The next few courses at least should be of large stones, so laid as to break joint thoroughly with those below. The trenches should be refilled with earth as soon as the masonry will permit; so as to exclude rain, which would injure the mortar, and soften the foundation. It is well to ram or tread the earth to some extent as it is being deposited.

If the tests show that the soil (not exposed to running water) is too soft to support the masonry, then the pits should be made considerably wider and deeper; and afterward be filled to their entire width, and to a depth of from 3 to 6 or more ft, (depending on the weight to be sustained,) with rammed or rolled layers of sand, gravel, or stone broken to turnpike size; or with concrete in which there is a good proportion of cement. On this deposit the masonry may be started. The common practice in such cases, of laying planks or wooden platforms in the foundations, for building upon, is a very bad one. For if the planks are not constantly kept thoroughly wet, they will decay in a few years; causing cracks and settlements in the masonry.

Some portions of the brick aqueduct † for supplying Boston with water gave a great deal of trouble where its trenches passed through running quicksands and other treacherous soils. Concrete was tried, but the wet quicksand mixed itself with it, and *killed* it. Wooden cradles, &c, also failed, and the difficulty was finally overcome by simply depositing in the trenches about two feet in depth of strong gravel.‡ Sand or gravel, *when prevented from spreading sideways*, forms one of the best of foundations. To prevent this spreading, the area to be built on may be surrounded by a wall; or by squared piles driven so close as to touch each other, or in less important cases, by short sheet piles only. But generally it is sufficient simply

* Subterranean caverns in limestone regions are a frequent source of trouble, against which it is difficult to adopt precautions.

† The Cochituate aqueduct, built 1846-48; egg-shape, 6 feet 4 inches × 5 feet, with semicircular invert.

‡ Smeaton mentions a stone bridge built upon a natural bed of gravel only about two feet thick, overlying deep mud so soft that an iron bar 40 feet long sank to the head by its own weight. One of the piers, however, sank while the arches were being turned, and was restored by Smeaton. Although a wretched precedent for bridge-building, this example illustrates the bearing power of a thick layer of well-compacted gravel.

to give the trenches a good width; and to ram the sand or gravel (which are all the better if wet) in layers, taking care to compact it well against the *sides* of the trench also Under heavy loads, some settlement will, of course, take place, as is the case in all foundations except rock. If very heavy, adopt piling, &c. See GRILLAGE.

When an unreliable soil overlies a firm one. but at such a depth that the excavation of the trenches (which then must evidently be made wider, as well as deeper) becomes too troublesome and expensive; especially when (as generally happens in that case) water percolates rapidly into the trenches from the adjacent strata, we may resort to piles When making deep foundation-pits in **damp clay.** we must remember that this material, being soft, has, to a certain degree, a tendency to press in every direction, like water. This causes it to bulge inward at the sides, and upward at the bottom The excavations for tunnels, or for vertical shafts, often close in all around, and become much contracted thereby before they can be lined, therefore they should be dug larger than would otherwise be necessary. The bottoms of canal and railroad excavations in moist clay are frequently pressed upward by the weight of the sides. **Dry clay** rapidly absorbs moisture from the air, and swells, producing effects similar to the foregoing Its expansion is attended by great pressure, so that retaining-walls backed with dry rammed clay will be in danger of bulging if the clay should become wet It is a treacherous material to work in **For concrete foundations.** see Concrete.

As to the greatest load that may safely be trusted on an earth foundation, Rankine advises not to exceed 1 to 1.5 tons per square foot But experience proves that on good compact gravel, sand, or loam, at a depth beyond atmospheric influences, 2 to 3 tons are safe, or even 4 to 6 tons if a few inches of settlement may be allowed, as is often the case in isolated structures without tremors Years may elapse before this settlement ceases entirely. Pure clay, especially if damp, is more compressible, and should not be trusted with more than 1 to 2.5 tons, according to the case All earth foundations must yield *somewhat.* **Equality of pressure** is a main point to aim at. **Tremor** increases settlements, and causes them to continue for a longer period, especially in weak soils. Great care must be taken not to overload in such cases, even if piled **Foundations in silty soils** will probably settle, in years, at the rate of from 3 to 12 inches per ton (up to 2 tons) per square foot of *quiet* load, if not on piles.

Figure 2 shows an easy mode of obtaining a foundation in certain cases. It is the "**pierre perdue**" (lost stone) of the French; in English, "**random stone,**" or **rip-rap.**

It is merely a deposit of rough angular quarry stone thrown into the water; the largest ones being at the outside, to resist disturbance from freshets, ice, floating trees, &c A part of the interior may be of small quarry chips, with some gravel, sand, clay, &c. When the bottom is irregular rock, this process saves the expense of levelling it off to receive the masonry. For 2 or 3 feet below the surface of the water, the stones may generally be disposed by hand, so as to lie close and firmly. Small spawls packed between the larger ones will make the work smoother, and less liable to be displaced by violence. Cramps or chains may at times be useful for connecting several of the large stones together for greater stability. **Rip-rap, however, is apt to settle.**

If the bottom is so yielding as to be liable to wash away in freshets, it may, in addition, be protected, as in Fig 2, by a covering of the same kind of stones, as at c; extending all around the structure. Or the main pile of stones may be extended as per dotted line at *d*; so that if the bottom should wash away, as per dotted line at *o*, the stones *d* will fall into the cavity, and thus prevent further damage. Sheet-piles, *s s*, may be driven as an additional precaution. For greater security, the bed of the river may be dredged or scooped under the entire space to be covered by the main deposit, as per dotted lines in Fig 3, to as great a depth as any scouring would be apt to reach;

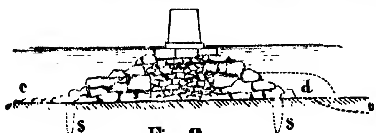

Fig 2

this excavation also to be filled with stone. Such foundations are evidently best adapted to quiet water. The masonry should rest on a strong platform.

Large deposits of stone, as in these two figs, greatly increase the velocity, and the scouring action of the stream around them, especially in freshets; unless the bottom on each side from the deposit be dredged out to such an extent that the original area of water shall not be reduced. If the bottom is treacherous, this should be done before depositing the covering stones c, Fig 2. Judgment and experience are necessary in such matters, as in all others connected with engineering. Mere study will not guard against constant failures. Theory and practice must guide each other.

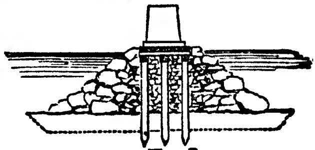

Fig 3

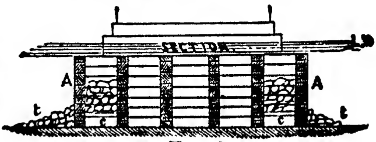
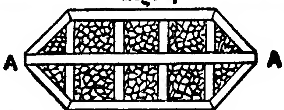
Fig 3 is another simple method; and when it does not create too great an obstruction to the navigation of the stream, or to the escape of its waters in time of high freshets, is a very effective one. Here the piles are first driven into the river bottom, for the support of the pier; then the deposit of stone is thrown in, for the support and protection of the piles; preventing them from bending under their loads; and shielding them from blows from floating bodies. The tops of the piles being cut off to a level, a strong platform of timber is laid on top of them, as a base for the masonry. The top of the platform should not be less than about 12 or 18 ins below ordinary low water, to prevent decay. Mitchell's iron screw pile; or hollow piles of cast iron, may be used instead of wooden ones.

Figs 4 represent a convenient method of establishing a foundation in water, by means of a **timber crib, A A, without a bottom.** It should be built of squared timbers, notched together at their crossings, as shown at Fig 5; each notch being ¼ of the depth of the stick. By this means each timber is supported throughout its entire length by the one below it; and resists pulling in both directions. Bolts also are driven at the intersections; at least in the sides of the crib, to prevent one portion from being floated off from the other. The crib is thus divided into square or rectangular cells, from 2 to 4 or 5 ft on a side, according to the requirements of the case. The partitions between the cells are put together in the same manner as those at the sides of the cribs; and consequently, like the latter, form solid wooden walls



Figs 4



PLAN.

Fig.5 t.

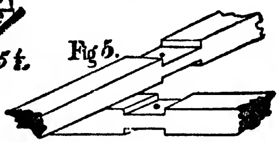


Fig 5.

The crib may be framed afloat, at any convenient spot; and when finished, may be towed to its final place, where it is carefully moored in position, and then sunk by throwing stone into a few cells provided with platforms, as at c c, for that purpose. These platforms should be placed a little above the lower edge of the cells, so as not to prevent the crib from settling slightly into the soil, and thus coming to a full bearing upon the bottom. After it has been sunk, all the cells are filled with rough stone. A stout top platform may be added or not, as the case may be; also, a protection, t t, of random stone, to prevent undermining by the current. If the sides are exposed to abrasion from ice, &c, they may be covered in whole or in part with plank, or plate iron; and the angles strengthened by iron straps, &c. In deep water, a foundation may be made partly of random stone, as in Figs 2 and 3; and on top of this may be sunk a crib, with its top about 2 ft under low water, as a base for the masonry. This is much safer than random stone alone.

On uneven rock bottom it may be necessary to scribe the bottom of the crib to fit the rock; or the crib may first be sunk by means of a loaded platform on its top, or by filling some of its cells, until its lowest timbers are within a short distance above the bottom. Being there kept in a horizontal position, small stones may be thrown into the cells, and allowed to find their way under the timbers of the crib, thus forming a level support for it. The cells may then be

A crib with only an outside row of cells for sinking it may be built; and the interior chamber may be filled with concrete under water. The masonry may then rest on the concrete alone. If the crib rests upon a foundation of broken stone, the upper interstices of this stone should first be levelled off by small stone or coarse gravel to receive the concrete of the inner chamber.

Or a crib like Fig. 4 may be sunk, and piles be driven in the cells, which may afterward be filled with broken stone or concrete. The masonry may then rest on the piles only. which in turn will be defended by the crib. If the bottom is liable to scour, place sheet-piles or rip-rap around the base of the crib.

By all means avoid a crib like ***e*****, Fig 5½,** much higher at one part than at another, *if the superstructure is to rest on the timber of the crib* instead of on piles, or on concrete independent of the timber; for the high part of the crib will compress more under its load than the low part, and will thus cause the superstructure to lean or to crack.

A crib either straight sided or circular, with only an outer row of cells for **puddling may be used as a cofferdam** (see cofferdams, p. 586). The joints between the outer timbers should be well caulked; and care be taken, by means of outside pile-planks, gravel, &c, to prevent water from entering beneath it.

The cast-iron Bridge across the Schuylkill at Chestnut St, Phila, Mr. Strickland Kneass, Engineer, affords a striking example of crib foundation. The center pier stands on a crib, an oblong octagon in plan, 31 by 87 feet at base; 24 by 80 ft at top, and (with its platform) 29 ft high. Its timbers are of yellow pine, hewn 12 ins square, and framed as at Fig 5. The lower timbers were carefully cut or scribed to conform to the irregularities of the tolerably level rock upon which it rests. These were ascertained (after the 8 ft depth of gravel had been dredged off) in the usual manner of mooring above the site a large floating wooden platform, composed of timbers corresponding in position with all those of the lower course of the intended crib, both longitudinal and transverse. Soundings were then taken close together along all these lines of timber. Most of the cells are about 3 by 4 ft on a side, in the clear. A few of them had platforms at the level of the second course from the bottom, for receiving stone for sinking the crib, the others are open to the bottom.

The crib was built in the water; and was kept floating, during its construction, with its unfinished top continually just above water, by gradually loading it with more stone as new timbers were added. The stone required for this purpose alone was 300 tons. When the crib was towed into position, and moored, 150 tons more were added for sinking it. All the cells were afterward filled with rough dry stone, and coarse gravel screenings, making a total of 1666 tons. A platform of 12 by 12 inch squared timber covered the whole, its top being 2½ ft below low water The pier alone, which stands on this crib, weighs 3255 tons, and during its construction it compressed the crib 6½ ins. The weight of superstructure resting on the pier, may be roughly taken at 1000 tons more.

An ordinary caisson is merely a strong scow, or a box without a lid; and with sides which may at pleasure be readily detached from its bottom. It is built on land, and then launched. The masonry may first be built in it, either in whole or in part, while afloat, and the whole being then towed into place, and moored may be sunk to the bottom of the river, to rest upon a foundation previously prepared for it, either by piling, if necessary; or by merely levelling off the natural surface, &c. The bottom of the caisson constitutes a strong timber platform, upon which the masonry rests; and is so arranged, that after it is sunk, the sides may be detached from it, and removed to be rebottomed for use at another pier, if needed. This detaching may be effected by some such contrivance as that shown in Fig 6, where P P *w* is the bottom of the caisson, to which are firmly attached at intervals strong iron eyes *t*; which are taken hold of by hooks *d*, at the lower end of long bolts E *n*, reaching to the top timbers S of the crib, where they are confined by screw nuts *n*. By loosening the nuts *n*, the hooks *d* can be detached from the eyes *t*; and the sides can then be removed from the bottom, there being no other connection between the two. These hooks and eyes are usually placed outside of the caisson; the screw nuts *n* being sustained by the projecting ends of cross pieces, as *t t*, Fig 9. The improper position given them in our Fig was merely for convenience of illustrating the principle. It will sometimes be necessary to have one side detachable from the others, in order to float the caisson away clear from the finished pier; unless it be floated away before the masonry has been built so high as to render the precaution useless.

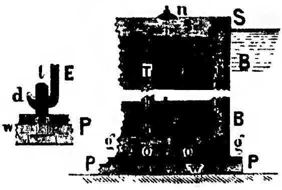

Fig 6.

Fig 6 shows one of many ways of constructing a caisson; with sides consisting of upright corner-posts, I; cap pieces S, on top; and sills *g* at bottom, resting on the bottom platform P P *w*; intermediate uprights T, framed into the caps and sills; the whole being covered outside by one or two thicknesses of planking B, which, as well as the platform, should be well calked, to prevent leaking. Tarpaulin also may be nailed outside to assist in this. The greatest trouble from leaking is where the sides join the platform. On top of the platform is firmly spiked a timber *o o*, extending all around it just inside of the inner lower edge of the sides of the caisson. Its use is to prevent the sides from being forced inward by the pressure of the water outside. The details of construction will of course vary with the requirements of the case. In deep caissons, inside cross-braces or struts from side to side, as at *c c*, Fig 7, will be required to prevent the sides from being forced inward by the pressure of the water, as the vessel gradually sinks while the masonry is being built within it. As the masonry is carried up, the struts are removed; and short ones, extending from the sides of the caisson to the masonry, are inserted in their place. When the caisson is shallow, only the upper course of braces will be required, they also support a platform for the workmen and their materials. In deep caissons, in order not to be in the way of the masons, the outer planking of the sides may, in part, be gradually built up as the masonry progresses. It may sometimes be expedient to build the masonry hollow at first, with thin transverse walls inside to stiffen it if necessary; and to com-

plete the interior after sinking the caisson. Indeed, masonry or brickwork, in cement, may thus be built hollow at first, resting on the platform; the masonry itself forming the sides of the caisson. Or the sides may consist of a water-tight casing of iron, or wood, of the shape of the intended pier, &c. This casing being confined to the platform, becomes, in fact, a mould, in which the pier may be formed, and sunk at the same time by filling it with hydraulic concrete. **For concrete foundations,** see Concrete.

On rock bottom the under timbers of the platform may be cut to suit the irregularities as already stated under "Cribs." Or the bottom may be levelled up by first depositing large stones around the area upon which the caisson is to rest; and then filling between these with smaller stones and gravel; testing the depth by sounding Or a level bed of cement concrete may, with care, be deposited in the water. If there are deep narrow crevices in the rock, through which the concrete may escape, they may be first covered with tarpaulin Diving bells may often be used to advantage, in all such operations. But in the case of very irregular rock, it will often be better to resort to coffer-dams.

Valves for the admission of water for sinking the caisson are usually introduced. If, after sinking, it should be necessary to again raise the whole, it is only necessary to close the valves, and pump out the water. Guide piles may be driven and braced alongside of the caisson, to insure its sinking vertically, and at the proper spot. Or it may be lowered by screws supported by strong temporary framework

Assuming the uprights I, T, &c, Fig 6, to be sufficiently braced, as at c c, Fig 7, the following table will show the thickness of planking necessary for different distances apart of the uprights, (in the clear,) to insure a safety of six against the pressure of the water at different depths; and at the same time not to bend inward under said pressure, more than $\frac{1}{480}$ part of the distance to which they stretch from upright to upright; or at the rate of ¼ inch in 10 ft stretch; ⅛ inch in 5 ft, &c. Such a table may be of use in other matters.

Table of thickness of white pine plank required not to bend more than $\frac{1}{480}$ part of its clear horizontal stretch, under different heads of water. (Original.)

Stretch in Ft.	HEADS IN FEET. 40	30	20	10	5
	Thickness in Inches.				
3	3½	3	2¾	2¼	1¾
4	4½	4	3½	2¾	2¼
6	6¾	6	5¼	4¼	3¼
8	9	8	7	5½	4½
10	11¼	10	8¾	7	5½
12	13½	12¼	10¾	8½	6¾
15	16¾	15	13	10½	8½
20	22¼	20	17½	14	11

Coffer-dams are enclosures from which the water may be pumped out, so as to allow the work to be done in the open air Their construction of course varies greatly. In still shallow water, a mere well-built bank of clay and gravel; or of bags partly filled with those materials when there is much current, will answer every purpose; or (depending on the depth) a single or double row of sheet-piles; or of squared piles of larger dimensions, driven touching each other; their lower ends a few feet in the soil; and their upper ones a little above high water, and protected outside by heaps of gravelly soil or puddle, (as at P in Fig 7,) to prevent leaking. The sheet-piles may be of wood; or of cast iron, of a strong form.

The sufficiency of a mere bank of well-packed earth in still water, is shown by the embankments or levees to prevent rivers from overflowing adjacent low lands The levees along 700 miles of the Mississippi average about 6 ft high; 3 ft wide on top; side-slopes 1½ to 1 In floods the river frequently bursts through them, doing immense damage. They are entirely too slight.

The method of a single row of 12 by 12 inch squared piles, driven in contact with each other, (close piles,) and simply backed by an outer deposit of impervious soil, is very effective; and with the addition of interior cross-braces or struts, like *c c*, Fig 7, to prevent crushing inward by the outside pressure of the water and puddle when pumped out, has been successfully employed in from 20 to 25 ft depth of water, in which there was not sufficient current to wash away the puddle. The cross-braces are inserted successively, as the water is being pumped out; beginning, of course, with the upper ones. The ends of these braces may abut on longitudinal timbers, bolted to the piles for the purpose. Another method is **a strong crib,** composed of uprights framed into caps and sills; and covered outside with squared timbers or plank, laid touching each other, and well calked; as in the caisson, Fig 6; but without a bottom. Between the opposite pairs of uprights are strong interior struts, as *c c*, Fig 7, reaching from side to side, to prevent crushing inward. The

upper series of these usually supports a platform for the workmen, windlasses, &c. The crib having been built on land, is launched, taken to its final place, and sunk by piling stones on a temporary platform resting on the cross-struts; the bottom of the stream having been previously levelled off, if necessary, for its reception.

To prevent leaking under the bottom of the crib, sheet-piles may be driven around it, their heads extending a few feet above its bottom, or a small deposit of outside puddle may be placed around it, as shown at the stone deposits *t t*, Fig 4. Or a broad flap of tarpaulin may be closely nailed around and a little above the lower edge of the crib, so arranged that it may be spread out loosely on the river bottom, to a width of a few feet all around the outside of the crib, and the puddle may be placed upon it. Such a tarpaulin is also very useful in case the river bottom is somewhat irregular, and cannot be levelled off without too great expense; in which case the crib cannot come to a full bearing upon it, and consequently the water would leak or flow beneath freely. It is especially adapted to uneven rock, where sheet-piles cannot be driven. An artificial stratum of impervious soil may however, be deposited on bare rock, in which case the sinking of the crib, and the subsequent operations will be the same as on a natural stratum. These expedients are evidently more or less applicable in other cases, where, to avoid repetition, they are not specially mentioned.

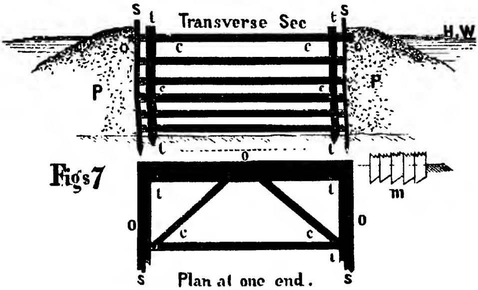

Fig 7 is another crib coffer-dam; in which the sides, instead of being planked longitudinally, as in the last instance, are sheathed with vertical sheet-piles *s*, driven after the crib is sunk. It is much inferior to the last, owing to its greater liability to leak. In one of this description, Fig 7, successfully used in 16 ft water, the dimensions of the crib were 34 ft by 80 ft. Along each long side were 7 uprights *t, t*, 19 ft long, 12 ins square, 12¾ ft apart. Into each opposite pair of these were notched, and held by dog-irons, 6 cross-braces *c c*, of 12 ins square. The distance between the two upper ones was 3 ft in the clear, gradually diminishing to 18 ins between the two lower ones, on account of the increased pressure of the water in descending. On the outside of the uprights, and opposite the ends of the braces, were bolted longi-

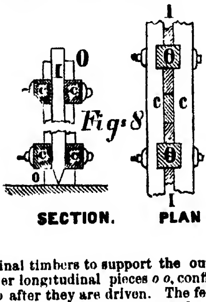
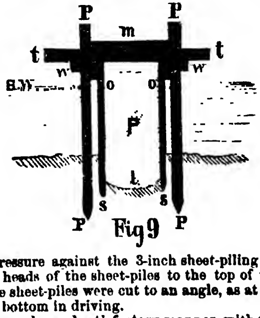




tudinal timbers to support the outside pressure against the 3-inch sheet-piling *s s*. Other longitudinal pieces *o o*, confine the heads of the sheet-piles to the top of the crib after they are driven. The feet of the sheet-piles were cut to an angle, as at *m*; to make them draw close to each other at bottom in driving.

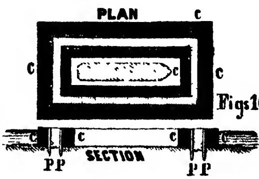
The sheet-piles will drive in a far more regular and satisfactory manner, with the arrangement shown in Figs 8. Here *o o* are the uprights; *c c* are pairs of longitudinal

pieces, notched and bolted to the uprights, near both their tops and their feet; and at as many intermediate points as may be desired. The sheet-piles I, are inserted between these; and of course are guided during their descent much more perfectly than in Fig 7.

When the current is too strong to permit the use of outside puddle, P, Fig 7, the principle of coffer-dam shown in Fig 9, is generally used; in which both sides of the puddle are protected from washing away. The space to be enclosed by the dam is surrounded by two rows of firmly-driven main piles *p p*, on which the strength chiefly depends. They may be round. In deciding upon their number, it must be remembered that they may have to resist floating ice, or accidental blows from vessels, &c. With reference to this, extra *fender*-piles may be driven. A little below the tops of the main piles are bolted two outside longitudinal pieces *w w*, called *wales;* and opposite to them two inner ones, as in the fig. The outer ones serve to support cross-timbers *t t*, which unite each pair of opposite piles, and steady them; and prevent their spreading apart by the pressure of the puddle P. The inner ones act as guides for the sheet-piles *s s*, while being driven; after which the heads of the sheet-piles are spiked to them. In deep water these sheet-piles must be very stout, say 12 ins square; to resist the pressure of the compacted puddle.

A gangway m, is often laid on top of the cross-pieces *t t*, for the use of the workmen in wheeling materials, &c. The puddle P is deposited in the water in the space, or boxing, between the sheet-piles. It should be put in in layers, and compacted as well as can be done without causing the sheet-piles to bulge, and thus open their joints. The bottom of the puddle-ditch should be deepened, as in the fig, in case it consists, as it often does, of loose porous material which would allow water to leak in beneath it and the sheet-piles. This leaking *under* the dam is frequently a source of much trouble and expense. Water will find its way readily through almost any depth and distance of clean coarse gravelly and pebbly bottom, unmixed with earth. Sand is also troublesome: and if a stratum of either should present itself extending to a great depth, it will generally be expedient to resort to either simple cribs, Fig 4; or to caissons; with or without piles in either case, according to circumstances. But if such open gravel, or any other permeable or shifting material, as soft mud, quicksand, &c, is present in a stratum but a few feet in thickness, and underlaid by stiff clay, or other safe material, leaking may be prevented, or at least much reduced, by driving the sheeting-piles 2 or 3 ft into this last, and by deepening the puddle-trench to the same extent. It may sometimes be better, and more convenient, to dredge away the bad material entirely from all the space to be enclosed by the dam, and for a short distance beyond, before commencing the construction of the latter. If the dam, Fig 9, is (as it should be) well provided with cross-braces, like *c c*, Fig 7, extending across the enclosed area, the thickness or width *o o* of the puddle, need not be more than 4 or 5 feet for shallow depths; or than 5 to 10 ft for great ones; because its use is then merely to prevent *leaking*. But if there are no braces, it must be made wider, so as to resist *upsetting* bodily; and then, with good puddle, *o o* may, as a rule of thumb, be ¾ of the vertical depth *o l* below high water; except when this gives less than 4 ft: in which case make it 4 ft; unless more should be required for the use of the workmen, for depositing materials, &c. Or if the excavation for the masonry is sunk deeper than the puddle, the dam must be wider, else it may be upset into the excavated pit.

The excavated soil may be raised in buckets by windlasses, or by hand, in successive stages. The pumps may be worked by hand, or by steam, as the case may require; as also the windlasses generally needed for lowering mortar, stone, &c. More or less leaking may always be anticipated, notwithstanding every precaution.



Figs 10

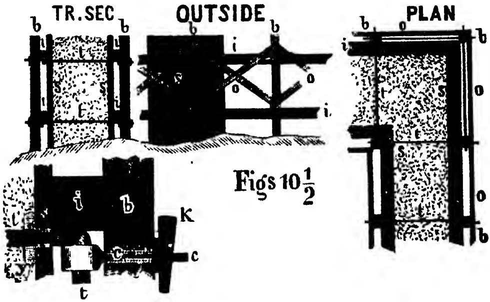
Where a coffer-dam is exposed to a violent current, and great danger from ice, &c, the expensive mode shown in Figs 10 may become necessary. The two black rectangles c c, represent two lines of rough cribs filled with stone, and sunk in position; one row being enclosed by the other; with a space several feet wide between them. Sheet-piles *p p* are then driven around the opposite faces of the two rows of cribs; and the puddle is deposited within the boxing thus provided for it, as shown in the fig.

Where the current is not strong enough to wash away gravel backing, we may, on rock especially, enclose the space to be built on, by a single quadrangle of cribs sunk by stone; and after adopting precautions to prevent the gravel from being pressed in beneath the cribs, apply the backing.*

Figs 10½ show the plan, outside view, and transverse section, to a scale of 20 ft to an inch, of a coffer-dam on rock, in 8 to 9 ft water, used successfully on the Schuylkill Navigation.

* A pure clean coarse gravel is entirely unfit for such purposes. A considerable proportion of earth is essential for preventing leaks.

Coffer-dam on rock. Uprights *b*, about 1 ft square, and 10 ft apart from center to center along the sides of the dam; and 10 ft in the clear, transversely of the dam, support two lines of horizontal stringers, *i i*; inside of which are the two lines of sheeting-piles, *s s*, enclosing between them a width of 7 ft of gravel puddle. Two flat iron bars (*t t*, of the transverse section) tie together each pair of uprights *b b*. These bars are ½ inch thick, by 2½ ins deep, and 9 ft long. Their hooked ends fit into eye-bolts *c*, which pass through the uprights *b*; outside of which they are fastened by keys, *k*, (see detail sketch.) Between the keys and *b*, were washers. At the corners of the dam (see plan) were additional tie-bars, as shown. A small band of straw, as seen at *y*, wrapped around the tie-bars just inside of the sheet-piles, and kept in place by the puddle; effectually prevented the leaking which generally proves so troublesome in such cases The stout oblique braces, *o o*, were merely spiked to the outside faces of the uprights *b*. They are not shown in the transverse section. This dam was built on shore, in sections 30 to 40 ft long. These were floated into place, and weighted down, sheet-piled, and puddled with gravel. The dam had sluices by which water was admitted when necessary for preventing the outside head from exceeding 9 ft. The lengths of the uprights *b b* were first found by careful soundings.



Figs 10½

The mooring of large caissons or cribs, preparatory to sinking them, is sometimes troublesome, especially in strong currents. It may be necessary to drive clumps of piles; or to temporarily sink rough cribs filled with stone, to which to attach the long guide-ropes by which the manœuvring into position, &c, is done. Frequently dams are left standing after the work is done; if not in the way of navigation, or otherwise objectionable; inasmuch as the materials are rarely worth the expense of removal. But if removed, the piles should not be *drawn* out of the ground; but be *cut off* close to river bottom; for if drawn, the water entering their holes may soften the soil under the masonry. It is often expedient to drive two rows of piles from the dam to the shore, for supporting a gangway for the workmen; or even for horses and carts, or for a railway for the easy delivery of large stones, &c.

Coffer-dams may be sunk through a soft to a firm soil, in shape of a box of cribwork, either rectangular or circular, and without a bottom. This being strongly put together, and provided with proper temporary internal bracing, (to be gradually removed as the masonry is built up,) is floated into place; and after being loaded so as to rest on the soft bottom, is sunk by dredging out the soft material from inside. Additional loading will sometimes be required for overcoming the friction of the soil against the outside; or it may even become necessary to dredge away some of the outer material also. **On rock** it may at times be expedient to drill holes in deep water, for receiving the ends of piles, or of iron rods, &c. This may be done by means of long drill-rods, working in an iron tube or pipe sunk as a guide to the rod; with its lower end over the spot to be bored Or a diving-bell may be used. Or **a cylinder** of staves 4 to 12 inches thick, long enough to reach above the surface, and having a broad tarpaulin flap or apron around its lower edge, to be covered with gravel to prevent leaking; may be sunk, and the water pumped out, to allow a workman to descend, and work in the open air.

Piles. When driven in close contact, as in Fig 11, for preventing leakage; for confining puddle in a coffer-dam: or for enclosing a piece of soft or sandy ground, to prevent its spreading when loaded; or if the outside soil should wash away from

around them, &c, they are called **sheet-piles.** Generally these are thinner than they are wide; but frequently they are square; and as large as bearing piles; and are then called **close piles.** To make them drive tight together at foot, they are cut obliquely as at *f*. Occasionally, when driven down to rock through soft soil, their feet are in addition cut to an edge, as at *i*, so as to become somewhat bruised when they reach the rock, and thus fit closer to its surface. Their heads are kept in line while driving, by means of either one or two longitudinal pieces *a* and *o*, called **wales** or *stringers*. These wales are supported by *gauge-piles*, or *guide-piles*, previously driven in the required line of the work, and several ft apart, for this purpose. See Figs 8.

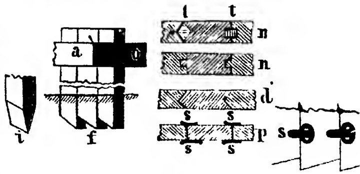


Fig 11

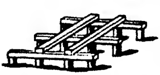
A dog-iron d, of round iron, may also be used for keeping the edges of the piles close at top to those previously driven, both during and after the driving. Its sharp ends, *c c*, being driven into the tops of the wales *w w*, (shown in plan,) it holds the descending pile *o* firmly in place. At *n*, *d*, *p*, Fig 11, are other modes occasionally used for keeping the piles in proper line. At *p*, the letters *s s* denote small pieces of iron well screwed to the piles, a little above their feet, to act as guides; very rarely used. At *m* are shown wooden tongues *t t*, sometimes driven down between the piles after they themselves have been driven; to assist in preventing leaks. In some cases sheet-piles are employed without being driven. A trench is first dug to their full depth for receiving them; and the piles are simply placed in these, which are then refilled. Closer joints can be secured in this manner than by driving.

Fig 12

When piles are intended to sustain loads on their tops, whether driven all their length into the ground, or only partly so, as in Fig 3, they are called **bearing piles.** They are generally round; from 9 to 18 ins diam at top; and should be straight, but the bark need not be removed. White pine, spruce, or even hemlock, answer very well in soft soils; good yellow pine for firmer ones; and hard oaks, elm, beech, &c, for the more compact ones. They are usually driven from about 2½ to 4 ft apart each way, from center to center, depending on the character of the soil, and the weight to be sustained. **A tread-wheel** is more economical than the winch for raising the hammer, when this is done by men. Morin found that the work performed by men working 8 hours per day, was 3900 foot-pounds per man, per minute by the tread-wheel; and only 2600 by a winch.

After piles have been driven, and their heads carefully sawed off to a level, if not under water, the spaces between them are in important cases filled up level with their tops with well rammed gravel, stone spawls, or concrete, in order to impart some sustaining power to the soil between the piles. Two courses of stout timbers (from 8 to 12 ins square, according to the weight to be carried) are then bolted or treenailed to the tops of the piles and to each other, as shown in the Fig, forming what is called a **grillage.** On top of these is bolted a floor or platform of thick plank for the support of the masonry; or the timbers of the upper course of the grillage may be laid close together to form the floor. The space below the floor should also, in important cases, be well packed with gravel, spawls, or concrete. **If under water,** the piles are sawed off by a diver, or by a circular saw driven by the engine of the pile-driver, and the grillage is omitted. Instead of it the masonry or concrete may be built in the open air in a caisson, which gradually sinks as it becomes filled; or on a strong platform which is lowered upon the piles by screws as the work progresses. Or a strong caisson may first be sunk entirely under water, and then be filled with concrete, up to near low water; the caisson being allowed to remain. Or the caisson may form a cofferdam, to be first sunk, and then pumped out. If the ground is liable



to wash away from around the piles, as in the case of bridge piers, &c, defend it by sheet-piles, or rip-rap, or both.

The cost of a floating steam pile driver, scow 24 ft by 50 ft. draft 18 ins, with one engine for driving, and one (to save time) for getting another pile ready; with one ton hammer, is about $6000; and $500 more will add a circular saw, &c, for sawing off piles at any reqd depth Requires engineman, cook, and 4 or 5 others. Will burn about half a ton of coal per day. Driving 20 feet into gravel, and sawing off, will average from 15 to 20 piles per day of 10 hours. In mud about twice as many. On land about half as many as in water.

In the gunpowder pile driver invented by the late Mr. Thomas Shaw, of Philadelphia, the hammer is worked by small cartridges of powder, placed one by one in a receptacle on top of the pile; and exploded by the hammer itself. It can readily make 30 to 40 blows of 5 to 10 ft per minute; and, since the hammer does not come into actual contact with the piles, it does not injure their heads at all; thus dispensing with iron hoops, &c, for preserving them. When only a slight blow is required, a smaller cartridge is used. To drive a pile 20 ft into mud averages about one-third of a pound of powder; into gravel, 4 times as much. This machine does not assist in raising the pile, and placing it in position, as is done by ordinary steam pile drivers; the latter, however, average but from 6 to 14 blows per minute.

Piles have been driven by exploding small charges of **dynamite** laid upon their heads, which are protected by iron-plates.

Steam-hammer pile drivers, operating on the principle of that devised by **Nasmyth** about 1850, are economical in driving to great depths in difficult soils where there are say 200 or more piles in clusters or rows, so that the machine can readily be moved from pile to pile.

The steam **cylinder** is upright, and is confined between the upper ends of two vertical and parallel I or channel **beams** about 6 to 12 ft long and 18 ins apart, the lower ends of which confine between them a hollow conical "**bonnet casting,**" which fits over the head of the pile. This casting is open at top, and through it the hammer, which is fastened to the foot of the piston-rod, strikes the head of the pile. Each of the vertical beams encloses one of the two upright guide-timbers, or "leaders," of the pile driver, between which the driving apparatus, above described, is free to slide up or down as a whole.

When a pile has been placed in position, ready for driving, the bonnet casting is placed upon its head, thus bringing the weight of the beams, cylinder, hammer, and casting upon the pile. This weight rests upon the pile throughout the driving, the apparatus sliding down between the leaders as the pile descends.

The steam is conveyed from the boiler to the cyl by a flexible pipe. When it is admitted to the cyl, the hammer is lifted about 30 or 40 ins, and upon its escape the hammer falls, striking the head of the pile. About 60 blows are delivered per minute. The hammer is provided with a trip-piece which automatically admits steam to the cylinder after each blow, and opens a valve for its escape at the end of the up-stroke. By altering the adjustment of this trip-piece, the length of stroke (and thus the force of the blows) can be increased or diminished. The admission and escape of steam, to and from the cyl, can also be controlled directly by the attendant. The number of blows per minute is increased or diminished by regulating the supply of steam.

In making the up-stroke, the steam, pressing against the lower cyl head, of course presses downward on the pile and aids its descent.

The chief advantage of these machines lies in the great rapidity with which the blows follow one another, allowing no time for the disturbed earth, sand, &c, to recompact itself around the sides, and under the foot, of the pile. This enables the machines to do work which cannot be done with ordinary pile drivers. They have driven Norway pine piles 42 ft into sand. They are less liable than others to split and broom the pile, so that these may be of softer and cheaper wood The bonnet casting keeps the head of the pile constantly in place, so that the piles do not "dodge" or get out of line. Their heads have, in some cases, been set on fire by the rapidly succeeding blows.

These machines consume from 1 to 2 tons of **coal** in 10 hours, and **require a crew** of 5 men. They work with a **boiler pressure** of from 50 to 75 lbs per sq inch.

Rules for the Sustaining Power of Piles.

They differ very much. No rule can apply correctly to all conditions. The ground itself between the piles, in most cases, supports a part of the load; although the whole of it is usually assigned to the piles. Again, in very clayey soils, there is greater liability to sink somewhat with the lapse of time, in consequence of the admission of water between the pile and the clay; thus diminishing the friction between them. The less firm the soil, the more will the piles be affected by tremors; which also tend in time to cause sinking. In some cases this sinking will not be that of the piles settling deeper into the earth *around* them; but that of the entire compacted mass of piles and earth into which they were driven, settling down into the less dense mass *below* them. Piles are sometimes blamed for settlements which are really due to the crushing (flatways) of the timbers which rest immediately upon their heads.

In the fine **London bridge** across the Thames, each pile under some of the piers sustains the very heavy load of 80 tons. They are driven but 20 feet into the stiff, blue London clay; and are placed nearly 4 ft apart from center to center; which is too much for such piers and arches. At 3 ft apart scant, they would have had but 45 tons to sustain. They are 1 ft in diam at the middle of their length. Ugly settlements, some of them to the extent of about a ft, have occurred under these piers. **Blackfriars bridge**, in the same vicinity, exhibits the same defect. By some this is ascribed in both cases to the gradual admission of water between the clay and the piles, perhaps by capillary action of the piles themselves; or perhaps by direct leaking. It may, however, be owing in part to the crushing of the platforms on top of the piles; or to a bodily settlement of the entire mass of piled clay, into the unpiled clay beneath, under the immense load that rests upon it. This here amounts to $5\frac{1}{2}$ tons per sq foot of area covered by a pier; and is probably too much to trust upon damp clay, when even the slightest sinking is prejudicial.

Maj J. Sanders, U. S. Engs, experimented largely at Fort Delaware in river mud; and gave the following in the Jour. Franklin Inst, Nov 1851. For the **safe** load for a common wooden pile, driven until it sinks through only small and nearly equal distances, under successive blows, divide the height of the fall in ins, by the small sinking at each blow in ins. Mult the quot by the weight of the hammer, ram, or monkey, in tons or pounds, as the case may be. Divide the prod by 8. He does not state any specific coefficient of safety.

Example. At the **Chestnut St Bridge,** Philada, the greatest weight on any pile is 18 tons. Mr Kneass had the piles driven until they sank $\frac{3}{4}$, or .75 of an inch under each blow from a 1200 ℔ hammer, falling 20 ft. Was he safe in doing so? Here we have the fall in ins = 20 × 12 = 240. And $\frac{240}{.75} = 320$; and 320 × 1200 = 384000 ℔s; and $\frac{384000}{8} = 48000$ ℔s, = 21.4 tons safe load by Maj Sanders' rule. The soil was river mud.

Our own rule is as follows. Mult together the cube rt of the fall in ft; the wt of hammer in ℔s; and the decimal .023. Divide the prod by the last sinking in ins. + 1. The quotient will be the **extreme load** that will be just at the point of causing more sinking. For the safe load take from one twelfth to one half of this, according to circumstances. Or, as a formula,

$$\underset{\text{in tons}}{\textbf{Extreme load}} = \frac{\begin{array}{c}\text{Cube rt of}\\ \text{fall in feet}\end{array} \times \begin{array}{c}\text{Wt of hammer}\\ \text{in pounds}\end{array} \times .023.}{\text{Last sinking in inches} + 1}.$$

Example. The same as the foregoing at Chestnut St Bridge. Here the cube rt of 20 ft fall is 2.714 ft. Hence we have

$$\underset{\text{in tons}}{\textbf{Extreme load}} = \frac{2.714 \times 1200 \times .023}{.75 + 1} = \frac{74.9}{1.75} = 42.8 \text{ tons.}$$

Or say half of this, or 21.4 tons, the load for a safety of 2. Major Sanders' rule makes the **safe** load 21.4. The actual one is 18 tons.

A safety of 2 is not enough for river mud.

But although Major Sanders' rule and our own agree very well in this instance *if a safety of 2 be taken for each*, they differ widely in some others. Thus at **Neuilly Bridge,** France, Perronet's heaviest hammer weighed 2000 ℔s, fall 5 ft, sinkage .25 of an inch in the last 16 blows; or say .016 inch per blow. The piles sustain 47 tons each. Our rule gives 38.8 tons for a safety of 2; while Sanders' rule gives 515 tons safe load! If, as we think probable, there was no actual sinking at the last blow, then our rule gives 39.3 tons for a safety of 2; while Sanders' gives infinity.

At the **Hull Docks,** England, piles 10 ins square, driven 16 ft into alluvial mud by a 1500 ℔ hammer, falling 24 ft, sank 2 ins per blow at the end of the driving. They sustain at least 20 tons each, or according to some statements 25 tons. Our rule gives 33.2 tons for the extreme load; or 16.6 for a safety of only 2. Sanders gives for *safety* 12.06 tons. As before remarked, 2 is not safety enough for mud. In mud, it is not primarily the piles, but the piled **soil** that settles, bodily, for years.

At the **Royal Border Bridge,** England, piles were very firmly driven from 30 to 40 ft in sand and gravel, in some cases wet. Pine was first tried, but it split and broomed so badly under the hard driving, that American elm was substituted, with success. They were driven until they sank but .08 inch per blow, under a 1700 ℔ monkey, falling 16 ft. They support 70 tons each. Our rule gives 47 tons for a safety of 2; while Sanders gives 364 tons safe load!

It is the writer's opinion, however, that the piles did not actually sink, as was (and always is, in such cases) taken for granted by the observers; but that they were merely compressed or partially crushed by overdriving. Most of the piles were driven until they sank (?) only an inch under 150 blows; but we doubt whether they were any safer, or farther in the ground, than when they had received only one of them; and consider such extreme precaution worse than useless.

In some experiments (1878) at Philada, a trial pile was driven 15 ft into soft river mud, by a 1600 ℔ hammer; its last sinking being 18 ins under a fall of 36 ft. Only 5 hours after it was driven it was loaded with 6.5 tons; which caused a sinking of but a very small fraction of an inch. Our rule

gives 6 4 tons as the extreme load. Under 9 tons it sank .75 of an inch; and under 15 tons, 5 ft. By Maj Sanders' rule its safe load would be 2.14 tons.

A U. S. Govt trial pile, about 12 ins sq, driven 29 ft through layers of silt, sand, and clay, hammer 910 lbs, fall 5 ft, last sinking .375 of an inch, bore 26.6 tons; but sank slowly under 27.9 tons. Our rule gives 26 tons extreme load.

French engineers consider a pile safe for a load of 25 tons, when it is driven to the refusal of 1344 lbs, falling 4 ft; our rule gives 24.2 tons for safety 2. They estimate the refusal by its not sinking more than 4 of an inch under 30 blows. In many important bridges &c they drive until there is no sinking under an 800 lb hammer, falling 5 ft. Our rule here gives 31.5 tons extreme load; or 15.7 for safety 2.

As to the proper load for safety, we think that not *more* than one-half the extreme load given by our rule should be taken for piles *thoroughly* driven in *firm* soils; nor more than one-sixth when in river mud or marsh; assuming, as we have hitherto done, that their feet do not rest upon rock.

If liable to tremors, take only **half** these loads.

Piles may be made of any required size as regards either length or cross section, by bolting and fishing together sidewise and lengthwise, a number of squared timbers.

Piles with blunt ends. At South Street Bridge, Phila, 1200 stout piles of Nova Scotia spruce with blunt ends were driven 15 to 35 ft. partly in strong gravel, by a common steam pile driver, at a total cost (piles and driving) of $7 to $8 each. At **Wilmington Harbor,** Cal, Mr. C. B. Sears, U S Army. (Jour. Am. Soc. C. E., Dec 1876) found that in firm compact wet sand, after the first few blows the piles would not penetrate more than .5 to 1.5 ins at a blow, no matter how far the 2400 lb hammer fell. The unpointed ones of which there were many thousands, drove quite as readily to average depths of 15 ft in this sand as the pointed ones, and with much less tendency to cant. As a high fall had no farther effect than to batter the heads he reduced it to 10 ft. which drove an average of about .72 inch to a blow. To insure straight driving, the ends must be at right angles to the length. **Instead of driving** piles to moderate depths it may at times be better to merely **plant** them butt down in holes bored by an auger like **Pierce's Well Borer.**

The ultimate friction of piles even with the bark on, and driven about 3 ft apart from cen to cen probably never much exceeds about 1 ton per sq ft even when well driven into dense moist sand or loamy gravel; nor more than .5 to .75 of a ton in common soils and clays; or than .1 to .2 of a ton in silt or wet river mud depending on the depth and density.

The friction of cast iron cylinders seems to be about .3 that of piles.

There is a great difference in the penetrability of different sands. Thus, in the Lary bridge, no special difficulty was found in driving piles 35 ft into deep wet sand, while, in other wet localities, piles of very tough wood, well shod with iron, cannot be driven 6 ft into sand, without being battered to pieces. The same difference has been found in the case of screw piles. At the Brandywine light-house these could not be forced more than 10 ft into the clean wet sand Stiff wet clay (and clean gravels) also differ very much in this respect Generally they are penetrable to any required depth with comparative ease, but we have seen stout hemlock piles battered to pieces in driving 6 ft through wet gravel, and Mr Rendel found that at Plymouth he "could not by any force drive screw-piles more than about 5 ft into the clay, which is not as stiff as the London clay," on which the forementioned new London and Blackfriars bridges were founded; and into which even ordinary wooden piles were driven 20 ft without special difficulty.

A mixture of mud with the sand or gravel facilitates driving very much; but before beginning an extensive system of piling, a few experimental ones should be driven, to remove doubt as to the trouble and expense that may be anticipated. Mere boring will often be but a poor substitute for this.

As a general rule, a heavy hammer with a low fall, drives more pleasantly than a light one with a high fall. Where a hammer of ⅔ ton (1500 lbs) falling 25 ft, in a very strong ground, shattered the piles; one of 2 tons, (4500 lbs,) with 7 ft fall, drove them satisfactorily. More blows can be made in the same time with a low fall; and this gives less time for the soil to compact itself around the piles between the blows. At times a pile may resist the hammer after sinking some distance; but start again after a short rest; or it may refuse a heavy hammer, and start under a lighter one. It may drive slowly at first, and more rapidly afterward, from causes that may be difficult to discover. The driving of one sometimes causes adjacent ones previously driven, to spring upward several feet. A pile is in the most favorable position when its foot rests upon rock, after its entire length has been driven through a firm soil, which affords perfect protection against its bending like an overloaded column; and at the same time creates great friction against its sides; thus assisting much in sustaining the load, and thereby relieving the pressure upon the foot. A pile may rest upon rock, and yet be very weak; for if driven through very soft soil, all the pressure is borne by the sharp point; and the pile becomes merely a column in a worse condition than a pillar with one rounded end. In such soils the piles need very little sharpening; indeed, had better be driven without any; or even butt end down.

The driving of a pile in soft ground or mud will generally cause an adjacent one previously driven, to lean outwards unless means be taken to prevent it.

In piling an area of firm soil it is best to begin at its center and work outwards; otherwise the soil may become so consolidated that the central ones can scarcely be driven at all.

Elastic reaction of the soil has been known to cause entire piled areas to rise, together with the piles, before they were built upon.

In very firm soil, especially if stony; or even in soft soil, if the piles are pointed, and are to be driven to rock; their feet should be protected by **shoes** of either wrought iron, as at *a*, *s*, and *b*, Figs 13; spiked to the pile by means of the iron straps *n*, forged to them; or of cast iron, as at *c*, where the shoe is a solid inverted cone, the wide flat base of which affords a good bearing for the flat bottom of the pile-point. The dotted line is a stout wrought-iron spike, well secured in the cone, which is cast around it; this holds the shoe to the pile. Regular

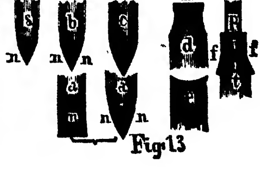


Fig 13

wrought-iron shoes will generally weigh 18 to 30 lbs; but sheet iron may be used when the soil is but moderately compact, plate iron when more so, and solid iron or steel points, from 2 to 4 ins square at the butt, and 4 to 8 ins long, when very compact and stony. **Holes may be drilled in rock** for receiving the points of piles, and thus preventing them from slipping, by first driving down a tube, as a guide to the drill, after the earth is cleaned out of the tube. **To preserve the heads** to some extent from splitting under the blows of the hammer, they are usually surrounded by a hoop *h*, Fig *d*, from ½ to 1 inch thick, and 1½ to 3 ins wide. These are, however, sometimes but imperfect aids; for in hard driving the head will crush, split, and bulge out on all sides, frequently for many feet below the hoop moreover, the hoops often split open The heads, therefore, often have to be sawed, or pared off several times before the pile is completely driven; and allowance must be made for this loss in ordering piles for any given work, especially in hard soil Capt Turnbull, U S Top Eng. states that at the Potomac aqueduct, his pileheads were preserved from injury by the simple expedient of dishing them out to a depth of about an inch, and covering them by a loose plate of sheet iron, as shown in section at *e*, Figs 13. A very slight degree of brooming or crushing of the head, materially diminishes the force of the ram. Piles may be driven through small loose rubble without much labor. Shaw's driver does not injure the heads. Piles which foot on sloping rock may slide when loaded.

To drive a pile head below water a wooden punch, or follower, as at *p*, Figs 13, may be used. The foot of this punch fits into the upper part of a casting *f f*, round or square, according to the shape of the pile, and having a transverse partition *o o* The lower part of the casting is fitted to the head of the pile *t*; and the hammer falls on top of the punch When driving piles vertically in very soft soil, to support retaining-walls, or other structures exposed to horizontal or inclined forces, care must be taken that these forces do not push over the piles themselves; for in such soils piles are adapted to resist vertical forces only, unless they be driven at an inclination corresponding to the oblique force.

A broken pile may be drawn out, or at least be started, if not very firmly driven, by attaching scows to it at low water, depending on the rising tide to loosen it Or a long timber may be used as a lever, with the head of an adjacent pile for its fulcrum Or a crab worked by the engine of the pile driver In very difficult cases the method devised by Mr J Monroe, C E, may be used. A 4 inch gas pipe 15 ft long, shod with a solid steel point, and having an outer shoulder for sustaining a circular punch, was thereby driven close to and 2 or 3 ft deeper than two piles driven 12 ft, in 37 ft water, and broken off by ice Four pounds of powder were then deposited in the lower end of the pipe, and exploded, lifting the piles completely out of place. It will often be best to let a broken pile remain, and to drive another close to it. May be drawn by hydraulic press.

Ice adheres to piles with a force of about 30 to 40 lbs per sq inch, and in rising water may lift them out of place if not sufficiently driven

Iron piles and cylinders. Cast iron in various shapes has been much used in Europe for sheet piles, especially when intended to remain as a facing for the protection of concrete work, filled in behind and against them * Cast iron cylinders, open at both ends, may be used as bearing piles; and may be cleaned out, and filled with concrete, if required The friction in driving is greater than in solid piles, inasmuch as it takes place along both the inner and the outer surfaces This may be diminished by gradually extracting the inside soil as they go down They require much care, and a lighter hammer, or less fall than wooden ones to prevent breaking, to which end a piece of wood should be interposed between the hammer and the pile, or the ram may be of wood. But it is better to use them in the shape of **screw cylinders**, which, moreover, gives them the advantage of a broad base as in the following

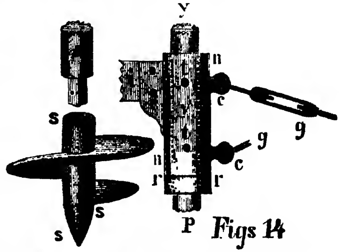
Brunel's process. He experimented with an open cast-iron cylinder, 3 ft outer diam; 1⅛ ins thick, in lengths of 10 ft, connected together by internal socket and joggle joints, secured by pins, and run with lead. It had a sharp edged hoop or cutter at bottom, and a little above this, one turn of a screw, with a pitch of 7 ins, and projecting one foot all around the outside of the cylinder. By means of capstan bars and winches, he screwed this down through stiff clay and sand, 58 feet to rock, on the bank of a river In descending this distance the cylinder made 142 revolutions; sinking on an average about 5 ins at each. The time occupied in actually screwing was 48¼ hours; or about $1\frac{2}{10}$ ft per hour. There were, however, many long intervals of rest for cleaning away the soil in the inside After resting, there was no great difficulty in restarting The next fig will give an idea of the arrangement of the screw.

The screw-pile of Alex. Mitchell, Belfast, consists usually of a rolled iron shaft A, Figs 14, from 3 to 8 ins diam, and having at its foot a cast-iron screw S S S, with a blade of from 18 ins to 5 ft diam. The screws used for light-houses, exposed to moderate seas, or heavy ice-fields, are ordinarily about 3 ft diam, have 1½ turns or threads, and weigh about 600 lbs The round rolled shafts are from 5 to 8 ins diam. They are screwed down from 10 to 20 ft into clay, sand, or coral, by about 30 to 40 men, pushing with 6 to 8 capstan bars, the ends of which describe a circle of about 30 to 40 ft diam. For this purpose a platform on piles has frequently to be prepared. In quiet water, this may be supported on scows; or a raft well moored may be used when the driving is easy; or the deck of a large scow with a well-hole in the center for the pile to pass through. Roughly made temporary cribs, filled with stone and sunk, might support a platform in some positions. The platform must evidently be able to resist revolving horizontally under the great pushing force of the men at the capstan bars; and on this account it is difficult to drive screws to a sufficient depth, in clean compact sand, by means of a floating platform. The feet of the piles must be firmly secured to the screws, to prevent

---

* **Cast iron, intended to resist sea-water,** should be close-grained, hard, white metal. In such, the small quantity of contained carbon is chemically combined with the metal; but in the darker or mottled irons it is mechanically combined and such iron soon becomes soft, (somewhat like plumbago,) when exposed to sea-water. Hard white iron has been proved to resist for at least 40 years without any deterioration, whether constantly under water, or alternately wet and dry. Copper and bronze are but slightly and superficially affected by sea-water; but destructive galvanic action takes place if diff metals are in contact.

their being lifted out of them by the upward force of waves against the superstructure. At *y p*, Figs 14, is shown a mode of splicing or uniting the different lengths or sections of a pile The point of junction is at *v*; *r r* is a stout iron ring forged on to the lower pile *p*, about a foot or 18 ins below its top *v*. A strong cylindrical casting *n n*, enclosing the ends of the sections, rests on this ring, and is pinned through the piles, as at *t t*. On this casting are also cast projections *c c c*, for attaching rods *g g*, and beams *i*, &c, necessary for bracing the structure from pile to pile. The time actually required for driving a screw is from 2 to 10 hours, in favorable circumstances.



Figs 14

At the Brandywine lighthouse, on a sand-bank of very pure sand covered 6 or 8 ft at low water, and from 11 to 13 ft at high, they could not be forced down, from a fixed platform, for more than 10 ft At other places 20 ft in sand is reached without much trouble, where the sand contains a good deal of mud, but its **bearing power** is then less This (ultimate) ranges between about 1 and 6 tons per sq ft according to purity, depth, compactness, &c, of the sand. In important cases the bearing power should be tested.

Mitchell's piles have been screwed about 40 feet into a mixture of clay and sand, with screws 4 ft diam. They pass through small broken stone and coral rock without much difficulty; and will push aside bowlders of moderate size. Ordinarily, clay or sand will present no great obstruction; but occasionally either of them will do so Perfectly pure clean sand, as a general rule, gives most difficulty. At the Brandywine shoal the driving was aided by a spur and pinion placed as low as the water permitted; and the levers were worked by 30 men. The danger of twisting off the shaft is the limit for screwing them They are much used for the anchoring of chains for mooring buoys, &c. On land, small screws, with short hollow shafts, make good durable supports for depot pillars, cranes, wooden telegraph poles, station signals in marine surveying, &c, &c. They can readily be unscrewed for removal Horses or oxen may be used in driving large screws. The Brandywine light-house stands on 9 screw-piles, which are surrounded by 30 others of 5 ins diam, as fenders. They have to resist not only moderate seas, but immense fields of floating ice, miles in extent. An unfinished structure was destroyed by ice, which at times injures the bracing of the standing one

Test borings should be made to ensure that the screws do not stop just above a very weak stratum which may endanger their bearing power So with *any* piles.

By means of a jet of water forcibly impelled through a tube by a force pump, the most obstinate sands will be loosened, and the sinking of screw piles, or wooden ones, or even the largest cylinders, be greatly facilitated In a government **pier at Cape Henlopen** in very compact sand, in which 6 out of 7 screws previously broke before reaching 10 ft, the use of the jet was found to remove more than three fourths of the resistance * The pile *p* to be sunk having first been placed in position as in Fig 15, the lower open ends *t t* of a bent iron tube *t s t* of one and a quarter ins bore were stood upon the upper face of the screw disk, and there held firmly by 3 or 4 men while the pile was being screwed down by the capstan *c*, which was worked by a leading rope *r*. From the bend *s* of the pipe, a hose *h*, 2 ins diam, led to the force pump, the cylinder of which was 5 ins bore, and 9 ins stroke, and worked about 80 full strokes per minute, by a mule walking on a tread wheel on a floating platform *f*. There was now no trouble in screwing the piles to any required depth Previous trials by playing the jet *beneath* the disk gave unsatisfactory results

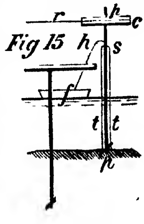


Fig 15

In Mobile Bay several thousands of wooden piles, from 18 to 48 ins diam, were sunk from 10 to 20 ft into obstinate sand, at the average sinking rate of about 1 ft per second, entirely by means of jets. The jet was propelled by a city steam fire engine, on a steamboat, through its own hose, with a one and a quarter inch nozzle. During the descent the nozzle *n n* was held loosely in its place near the foot of the pile, by two staples *s s* and by a string *t* reaching to the surface. The piles were suspended by their heads from shears, by the tackle of which their descent was regulated The sand settled firmly around the piles in a few minutes after they were sunk.†

At Tensas River, Alabama, for iron cylinders 6 ft diam (enclosing piles, in deep light shifting sand, the jet was forced by a small rotary pump of 200 to 300 revolutions per minute, through a canvas hose 3 ins diam, into a central conical cast iron vessel 10 ins diam. from which radiated 12 gas pipes 1 inch diam, and about 30 ins long. At the outer end of each of these radii was an elbow to which was attached a long vertical pipe reaching down into the cylinder, and made in 10 ft lengths with screw ends for prolonging them as the cylinder went down. This apparatus was raised and lowered by a light block and line; and by it alone each cylinder was sunk about 16 ft into the light sand in a few hours.‡

---

* Report Sec of War 1872. † John W. Glenn, C E, Van Nostrand, June 1874.
‡ Gabriel Jordan, C E; Trans Am Soc C E, Feb 1874.

At the Levan Viaduct, Mr James Brunlee, England, in a light sandy marl of great depth, sunk hollow cast iron cylinders of 10 ins outer diam, to a depth of 20 ft, by means of a jet pipe 2 ins diam passing down inside of the cylinder, and through a hole in its base, which was a cast iron disk 30 ins diam, and 1 inch thick, strengthened by outside flanges. The connecting flanges of the cylinder sections are *outside*, thus impeding the descent, as did also the broad bottom disk; still 3 or 4 hours usually sufficed for the sinking of each, to 20 ft depth. Actual trial showed that their safe sustaining power was about 5 tons per sq ft of bottom disk

At Lock Ken viaduct each pier consists of two cylinders, open at both ends; of cast iron, 8 ft in diam; $1\frac{1}{8}$ ins thick; in lengths of 6 ft, weighing 4 tons each; and bolted together by inside flanges, with iron cement between them. The cylinders stand 8 ft apart in the clear; and are in 36 ft water. "A strong staging was erected; and 4 guide-piles driven for each cylinder. The several lengths being previously bolted together, these were lowered into their places Each cylinder sunk by its own weight one or two ft through the top mud, and then settled upon the sand and gravel which form the substratum for a great depth Into this last they were sunk about 8 or 9 ft farther, by excavating the inside earth under water, by means of an inverted conical **screw-pan,** or dredger, of $\frac{1}{4}$ inch plate iron. This was 2 ft greatest diam, and 1 ft deep; and to its bottom was attached a screw about 1 ft long, for assisting in screwing it down into the soil. Its sides had openings for the entrance of the soil; and leather flaps, opening inward, to prevent its escape. From opposite sides of the pan, 3 rods of $\frac{3}{4}$ inch diam projected upward 4 feet, and were there forged together, and connected by an eye-and-bolt joint to a long rod or shaft, at the upper end of which was a four-armed cross-handle, by which the pan was screwed down by 4 men on the staging."

"When a pan was full, a slide which passed over the joint at the bottom was lifted; and the pan was raised by a tackle. This pan raised about 1 cub ft at a time. A smaller one of only 1 ft diam, and 1 ft deep, raising about $\frac{1}{4}$ cub ft, was used when the material was very hard. By this means the cylinders were sunk at the rate of from 2 to 18 ins per day. The slow rate of 2 ins was caused by stones some of them of 50 lbs. These were first loosened by a screw-pick, which was a bar of iron 3 ft long, with circular arms 12 ins long projecting from the sides. After being loosened by this, the stones were raised by the pan. The expense of all this apparatus was very trifling; and the excavation was done easily and cheaply. After the excavation was finished, and the cylinder sunk, before pumping out the water, concrete (gravel 2, hydraulic cement 1 measure) was filled in to the depth of 12 feet, by means of a large pan with a movable bottom; and about 12 days were left it to harden The water was then pumped out, and the masonry built in open air In some of the cylinders, however, the water rose so fast, notwithstanding the 12 ft of concrete, that the pumps could not keep them clear, and 6 ft more of concrete had to be added in those Finally random-stone, or rough dry rubble, was thrown in around the outsides of the cylinders, to preserve them from blows and undermining."* The masonry extends 20 ft above the cylinders, and above water.

The vacuum and plenum processes. We can barely allude to the general principles of these two modes of sinking large hollow iron cylinders In the **vacuum process** of Dr. Lawrence Holker Potts, of London, the cylinder *c*, Fig 16, while being sunk, is closed air-tight at top, by a trap-door, opening upward A flexible pipe *p*, of India-rubber, long enough to adapt itself to the sinking of the cylinder, and provided with a stopcock *s*, leads from the cylinder to a vessel *v*; which may be placed on a raft, or a scow, or on land, as may suit circumstances. The cylinder being first stood up in position, as in the fig, the water is pumped out, and the interior soil removed if the cylinder has sunk some distance by its own weight The cock *s* is then closed, and the air is drawn out from the vessel *v* by an air-pump. The cock is then opened, and most of the air in the cylinder rushes into the void vessel *v*; thus leaving the cylinder comparatively empty, and therefore less capable of resisting the downward pressure of the external air upon its top This pressure, as is well known, amounts to nearly 15 lbs on every sq inch; or nearly 1 ton per sq ft of area of the top. Consequently the cylinder is forced downward in the bed of the river, by this amount of pressure, in addition to its own weight. At the same time, the pressure of the air upon the surface of the water is transmitted through the water to the soil around the open foot of the cylinder; so that if this soil be soft or semi-fluid, it will be pressed up into the nearly void cylinder, in which is no downward pressure to resist it. The descent varies from a few inches, to 4 or 5 ft each time. The process is then repeated, by admitting air again into the cylinder, opening the trap-door, removing the water and soil, as before, &c. Additional lengths of cylinder may be bolted on, by means of interior flanges.

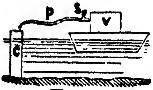

Fig 16

It is **adapted only to soft soils,** and to wet sandy ones; but is not sufficiently powerful in very compact ones; nor does it answer where obstructions from bowlders, logs, &c. occur.

***Hollow Iron Piles** either cast or wrought with solid pointed feet, to be driven by the hammer falling *inside* of them and striking against the top of the solid foot, are a recent device of great use in many cases. They are made in sections of which enough can be gradually united to reach any required depth. They avoid the danger of bending which attends striking the top. The iron feet are swelled outwardly a little to diminish earth-friction against the pile above them.

the removal of which requires men to enter the cylinder to its foot; which they cannot do in the rarefied air. The pipe *p* should be of sufficient diam to allow the air to leave the cylinder rapidly, so that the outer pressure may act upon the top as suddenly as possible.

At the Goodwin Sands light-house, England, hollow cylinders 2½ ft in diam, were sunk 34 ft into sand by this process, in about 6 hours; where a steel bar could be driven only 8 ft by a sledge-hammer. Others, 12 ins in diam, have been sunk 16 ft into sand within less than an hour. In this last instance the air-pump had two barrels, 4½ ins diam, 16 inch stroke, worked by 4 men. The pipe *p* was of lead, and only ½ inch diam.

The plenum process, invented by Mr Triger, of France, consists in forcing air into the cylinder C C, Fig 17, to such an extent as to force out the water, compelling it to escape beneath the open foot, into the surrounding water. The interior of the cylinder being thus left dry to the bottom, men pass down it to loosen and remove the soil at and below its base. When this is done, they leave; the compressed air is allowed to escape; and the cylinder, being no longer sustained by the upward pressure of the compressed air beneath its top, sinks into the cavity, or the loosened material at its foot. Fig 17 shows the simple arrangement by which workmen are enabled to enter or leave the cylinder, without allowing the compressed air to escape; as well as the general principle of the entire process.

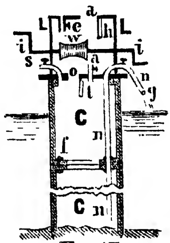

Fig 17

L L is a separate small chamber, **the air-lock**, which is removed when a new length of pipe is to be added; and afterward replaced and firmly bolted on. This chamber has a small air-tight door *d*, by which it can be entered from without, and another, *o*, opening into the cylinder. The flaps, *t*, *k*, of both doors, open inward, or toward the cylinder. This chamber also has two stopcocks; one, *a*, in its floor, communicating with the cylinder, and one *e*, above, communicating with the open air. At *s* is a bent tube, also with a cock, which passes air-tight through the side and the bottom of the air-lock. Through it the compressed air is forced into the cylinder by an air force pump or condenser, and through it the same air is allowed to escape at a later period. A siphon is shown at *n n n*. A drum *w* is used for hoisting the excavated material from the bottom, to the air-lock; its axle *i i* passes air-tight through stuffing boxes in the sides of the lock; the hoisting being done by men outside. This is the general arrangement employed by Mr W. J. McAlpine, C E, of New York, at Harlem bridge; and from his description of it, ours has been condensed. The cylinders were there 6 ft diam, 1¾ ins thick, and in lengths of 9 ft, bolted together through inside flanges *f*, as the sinking went on. The air-lock is 6 ft diam, by nearly 6 ft high; with sides of boiler iron; and top and bottom of cast iron.

Now suppose the cylinder C C to be let down, and steadied in position, as in the fig; and the air-lock L L to be adjusted on top of it. The next process is to force in air through the curved tube *s* the flap *t* of the lower door *o*, and the cock *a*, being previously closed. As the compressed air accumulates in the cylinder, it forces out the water; which escapes partly beneath the bottom of the cylinder, and partly by rising through the siphon *n n*, and flowing out at *g*. The door *o* being already closed, and that at *d* open, the air in the air-lock is in the same condition as that outside; so that workmen can enter it readily. Having done so, they close the door *d*, and the cock *e*, and open the cock *a*, through which condensed air from the cylinder rushes upward, soon filling the air-lock. When this is done, the flap *t* is opened, and the men descend through the door *o* by a ladder, or by a bucket lowered by the drum *w*, to the bottom. Here they loosen and excavate the material as deep as they can; and, filling it into a bucket or bag, they signal to those outside, who raise it to the air-lock. When done, they ascend to the air-lock, close the door *o*, and the cock *a*; and open the cock *e*, through which the condensed air in the lock soon escapes, leaving the internal air the same as that outside. The door *d* is then opened, the buckets of earth are removed, and the men go out. Finally the cock at *s* is opened, the condensed air in the cylinder escapes through it to the outside air, and the cylinder sinks by its own weight into the cavity and loosened soil prepared for it at its base, and which is now forced up into the cylinder by the rush of the returning water. The process is then repeated. The sinking will often vary from 0 to 10 or more feet at one operation. Until depths of 40 or 50 ft, most men can endure the pressure of the condensed air; but as the depth increases this becomes more difficult, and positively dangerous to life. Cast-iron cylinders 15 ft diam; and great caissons, Fig 18, have been thus sunk; but at times at great expense and trouble.

The cylinder should be guided in its descent by a strong frame, which may be supported by piles. Otherwise it will be apt to tilt, and thus give great trouble to settle it upon its exact place. Have been sunk in deep water by divers undermining inside.

The plenum process as applied at the South St bridge, Philada by Mr John W. Murphy, contracting engineer, differs materially from that described above; and moreover deserves notice on account of the great simplicity and efficacy of his plant. This consisted partly of two canal boats, decked, each 100 ft long, by 17½ ft wide, and 8 ft depth of hold. They were anchored parallel to each other, 15 ft apart. Supported by the boats, and over the space between them, was a strong four-legged shears about 50 ft high; at the top of which was attached tackle for handling the cast iron cylinders. In the hold of one of the boats was a **Burleigh Compressor** having two pistons of 10 ins diam, and 9 ins stroke; together with its boiler. On the deck of the same boat stood a vertical **air-tank or regulator** 22 ft long, by 2 ft diam, made of quarter inch boiler iron. This served to maintain a supply of compressed air in the submerged cylinder in case of an accidental stopping of the compressor; which otherwise would probably be fatal to the laborers in the cylinder. The condensed air flowed from this air tank to the air-lock of the cylinder through a hose 4 ins diam, made of gum elastic and canvas, and so long, and so placed, as to extend itself as the cylinder went down, thus maintaining the communication at all times. Entirely across both boats, and across the interval between them, extended two heavy wooden **clamps**, each 3 ft wide by 18 ins high; each compose

of three pieces of 12 × 18 inch timber strongly bolted together. At the centers of these clamps the two inner vertical sides which faced each other were hollowed out to the depth of a foot by concavities corresponding to the curve of the cylinders. The distance apart of the clamps was regulated by two strong iron rods, having screws and nuts at their ends for that purpose. Thus when a section of a cylinder was hoisted by means of the shears into its position over the space between the two boats, the two concavities of the clamps were brought into contact with it, and the nuts being then screwed up, the cylinder was firmly held in place by the clamps. The shears could then be used to raise another section of the cylinder to its place upon the first one, that the two might be bolted together. By repeating this process the height of the cylinder would soon become too great to allow the shears to place another section upon it, in which case the nuts of the screws were slightly loosened, and the cylinder was allowed to slip down slowly into the water until its top was but a little above the surface. The screws were then again tightened, and the cylinder again held fast until other sections were added and bolted to it. When there was danger that the upward pressure of the condensed air might lift a cylinder, the clamps were raised by the shears clear of the boats, then tightened to the cylinder, and a platform of planks laid upon them, and loaded with stone

The **air-lock** was so arranged as not to require to be removed when a new section was to be bolted on This was effected as follows. Sections of the cylinder were bolted together in the manner just described, until its foot rested on the bottom, with its top a few feet above high water. A heavy cast iron **diaphragm** 1¼ inches thick, to form the floor of the air-lock, was then placed on top. Then was added another 10 ft high section of the cylinder, to form the chamber of the air-lock. These were bolted together, and then another diaphragm was added at top to form the roof of the air-lock. These diaphragms were furnished with openings, and with doors and valves corresponding with those shown in Fig 17, and remained permanently in the cylinders when the work was finished If the depth of soil to be passed through before reaching rock is so great as to require other sections of cylinder to be bolted on above the top of the air-lock this may be done to any extent, inasmuch as it is immaterial whether the air-lock is under water or not. **To keep the cylinder both air- and water-tight** the faces of the flanges before being bolted together were smeared with a mixture of red and white lead and cotton fiber

South St. bridge, Philadelphia. D. M. Stauffer, Franklin Inst. Jour Nov 1872. Thirteen cast iron cylinders, in 10 ft lengths, 1¼ ins thick; 4, 6, and 8 ft diam; weighing, resp, 6800, 10800, 14600 lbs, diaframs 783, 1600, 2800 lbs resp. Inside flanges 2¾ ins wide, 1¼ ins thick, with bolt-holes 1¼ ins diam, 5 ins apart c. c. The bottom edge has no flange. The work went on, day and night, summer and winter: with no interruption from the tides, floods, or floating ice; and the thirteen cyls were sunk, filled with concrete, and **completed in 11 months**; much of which was consumed in leveling off the rock, and bolting the cyls to it by means of cast iron brackets. The want of guides caused much tilting, trouble and delay. Range of tide abt 7 ft. Water abt 25 ft deep. Depth of soil, gravel, etc, 6 to 30 ft. **Cost** of cylinders, in place, filled with concrete, $40, $64, $92 resp per ft of total length. Three gangs of men; each gang workt 4 hours at a time.

Chestnut St. bridge, Philadelphia. 1884–5. Four wrot-iron cyls, 8 ft diam, 66 ft long, **at 45° with the hor,** intended as struts to prevent the movement of one of the abut piers.

Cast iron cylinders have cracked thru, around their entire circumference, in many parts of the U. S. in very cold weather; owing to **diff of contraction** betw the iron and the concrete filling.

The shaded part of Fig 18 shows a transverse section of the **caisson of yellow-pine** timber and cement, for the **Brooklyn tower of East River** (N Y) suspension bridge, of 1600 ft clear span. It is 168 ft long at bottom, and 102 ft wide. A longitudinal section resembles the transverse one, except in being longer, and in showing more shafts J. Of these there are 6, arranged in pairs, for expedition and as a precaution against accident. Namely, two water-shafts J, each 7 ft by 6½ ft across, for removing by buckets and hoisting apparatus, the material excavated beneath the caisson; together with such water as may accumulate at *o o*; two air-shafts of 21 ins diam, through which air is forced from above, to expel the water from the chamber C S S D below the caisson, so as to allow the laborers to work there at undermining; the expelled water escaping under the foot C D of the caisson, into the river; and two supply shafts of 42 ins diam, for admitting laborers, tools, &c. The several shafts of course have air-chambers on top, on the same principle as Fig 17, to prevent the escape of the compressed air in *s s*.

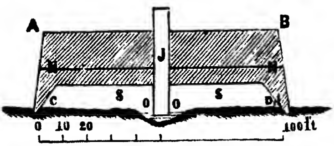

Fig 18

The shafts are of ¼ inch boiler iron. The foot C D, nine timbers high, is continuous, extending entirely around the caisson; its bottom is shod with cast iron; its four corners are strengthened by wooden knees 20 ft long.

From the bottom, up to the line N, N, 14 ft, the caisson is built of horizontal layers of timbers one foot square; the layers crossing each other at right angles; and the timbers of each layer touching each other well forced and bolted together; and all the joints filled with pitch. To aid in preventing leakage, the nuts and heads of the screws have India-rubber washers, also all outside seams, as well as all the seams of the layer of timbers N, N, are thoroughly calked; and a layer of tin, enclosed between two layers of felt, is placed outside of each outer joint; and over the entire top of the layer next below N, N.

When the caisson was built up to N, N, on land, it was launched, floated into position, and anchored; after which were added for sinking it, fifteen courses of timbers one ft square; and laid one ft apart in the clear; with the intervals filled with concrete. The top course A B is of solid timber, to serve as a floor for supporting machinery, &c. It was sunk some feet below the very bottom of the river, in order to avoid the teredo.

Cribs are sunk outside of the caisson, to form temporary wharves for boats carrying away excavated material; and for vessels bringing stone, &c.

When the caisson was sunk, and the water forced out from the chamber or space C S S D, workmen began to excavate uniformly the enclosed area of river bottom, so as to allow the caisson to descend slowly until it reached a firm substratum. The space C S S D, as well as the shafts, was then filled up solid with concrete masonry. A coffer-dam was built on top of the caisson, and in it the regular masonry of the tower was started. The total height of this tower including the caisson, is about 300 ft For full details see report, 1873, of W. A. Roebling the chief engineer

Hollow cylinders, or other forms of brickwork or masonry, with a strong curb or open ring of timber or iron beneath them, may be gradually sunk by undermining and excavating from the inside, and form very stable foundations. Under water this may be done by properly shaped scoops, with or without the aid of the diving-bell, according to the depth, &c. On land it will often be the most economical and satisfactory mode, especially in firm soils. The descent may be assisted by loading them, if, as sometimes happens, the friction of their sides against the earth outside prevents their sinking by their own weight. A brick cylinder, 46 ft outer diam, walls 3 ft thick, has been sunk 40 ft in dry sand and gravel, without any difficulty. It was built 18 ft high, (on a wooden curb 21 ins thick,) and weighed 300 tons before the sinking was begun. The interior earth was excavated slowly, so that the sinking was about 1 ft per day; the walls being built up as it sank. Tunnel shafts are at times so sunk.

On the Rhine for a coal shaft, a brick cylinder 25½ feet diam was first thus sunk by its own weight 76 ft through sand and gravel; then an interior one, 15 ft diam, was sunk in the same way to the depth of 256 ft below the surface, of which depth all the 180 ft below the first cylinder was a running quicksand. At 256 ft friction rendered the cylinder immovable. The quick sand was removed by boring; no pumping was done; but the water was permitted to keep the cyl full.

The entire foundation for a large pier of masonry has been sunk in this manner, in a single mass; a sufficient number of vertical openings being left in it for the workmen to descend, or for tools to be inserted for undermining. This is generally a very slow and tedious operation, especially under water. It may often be expedited by diving-bells or by diving-dresses. It will generally be better to make the mass wider at bottom than above it, so as to diminish friction against the outside earth. On land, water may at times be used for softening the bottom earth. By keeping the interior of such hollow masonry dry, it may even be *built downward* from the surface; by undermining only a portion of its circumference at a time, filling said portion with masonry, and then removing and filling the other portion; and so on in successive stages of 2 or 3 ft downward at a time. This mode may be adopted also when friction has stopped the sinking of a mass by its own weight when undermined.

The sand pump as used at the St Louis bridge will often be of service in raising sand from cylinders while being sunk in water. With a pump pipe of 3.5 ins bore, and a water jet under a pressure of 150 lbs per sq inch, 20 cub yds of sand per hour were raised 125 feet. A jet of air has also been successfully used in the same way, as at the East River, N Y, suspension bridge, &c.

Fascines. On marshy or wet quicksand bottoms, foundations may be laid by first depositing large areas of layers of fascines, or stout twigs and small branches, strongly tied together in bundles from 6 to 12 ft long, and from 6 ins to 2 ft in diam.

The layers or strata of bundles should cross each other. A kind of floating raft or large mattress is first made of these, and then sunk to the bottom by being loaded with earth, gravel, stones, &c In this manner the abutments and piers of the great suspension bridge at Kieff, in Russia, with spans of 440 ft, were founded in 1852, on a shifting quicksand. There the fascine mattresses extend 100 ft beyond the bases of the masonry which rests upon them

Fascines may be used in the same way for sustaining railway embankments, &c, over marshy ground, but they will settle considerably.

Sand-piles. We have already alluded to the use of sand well rammed in layers into trenches or foundation pits; but it may also be used in soft soils, in the shape of piles. A short stout wooden pile is first driven 5 to 10 feet or more, according to the case. It is then drawn out, and the hole is filled with wet sand well rammed. The pile is then again driven in another place, and the process repeated. The intervals may be from 1 to 3 ft in the clear. Platforms may be used on these piles as on wooden ones. If the sand is not put in wet, it will be in danger of afterward sinking from rain or spring water. In this case, as with fascines, it is well to test the foundation by means of trial loads. Some settlement must inevitably take place until all the parts come to a full bearing; but it will be *comparatively* trifling. The same occurs in every large work to some extent; as in a roof or arch of great span, whether of wood, iron, or masonry; so also with all tall piers, walls, &c, &c. Sandy foundations under water should be surrounded by stout well-driven sheet-piling, to prevent the enclosed sand from running out in case the outer sand is washed away; and should also be defended by a deposit of random-stone.

On bad bottoms under water, **small artificial islands** of good soil have been deposited; and the masonry founded upon them. Canal locks and other structures may at times be advantageously founded in this way in marshy soils. If necessary, a depth of several feet of the bad soil may be dredged out before the firmer soil is deposited; and the latter may be weighted by a trial load to test its stability.

The mode of laying a foundation under water, by building the masonry upon a timber platform above water, upheld by **strong screws**, and lowered into the water as the work is finished in the open air, a course or two at a time, has of late been much employed with entire success, in large bridge-piers in deep water. It however is not new. It was suggested more than 100 years ago by Belidor.

Piles are driven 6 to 10 ft apart around the space to be occupied by the pier; having their tops connected by heavy timber cap-pieces. These last uphold the screws, which work through them. The whole is braced against lateral motion.

A CLUMP OF PILES WELL DRIVEN; and then enclosed by an iron cylinder sunk to a firm bearing, and filled with concrete, is an excellent foundation. The piles may extend to the top of the cylinder, and thus be enclosed in the concrete. Such an arrangement has been patented by S. B. Cushing, C. E., Providence, R. I. The cylinder and concrete serve to protect the piles from sea-worms, and from decay above low water; and are not intended to support the load above them.

STONEWORK.

Where work is done on a large scale, blasting can sometimes be done at from 10 to 20 per cent less cost per cubic yard by means of **machine drills and dynamite,** than by **hand drills and gunpowder.** Ordinarily, however, **the cost is about the same,** and the advantage of the newer methods consists rather in economy of time, convenience, and having the work more entirely under control. In ordinary railroad work in average hard rock, and when common labor costs $1 per day of ten hours, the cost per cubic yard, for loosening, will ordinarily range between 30 and 60 cts, including tools, drilling, powder, &c.

Holes for blasting, drilled by hand, are generally from $2\frac{1}{2}$ to 4 ft deep; and from $1\frac{1}{4}$ to 2 ins diam. **Churn-drilling** is much more expeditious and economical than that by *jumping*, mentioned below. The churn-drill is merely a round iron bar, usually about $1\frac{1}{4}$ ins diam, and 6 to 8 ft long; with a steel cutting edge, or bit, (weighing about a lb, and a little wider than the diam of the bar,) welded to its lower end. A man lifts it a few inches; or rather catches it as it rebounds, turns it partially around; and lets it fall again. By this means he drills from 5 to 15 feet of hole, nearly 2 ins diam, in a day of 10 working hours, depending on the character of the rock. From 7 to 8 ft of holes $1\frac{1}{4}$ ins diam, is about a fair day's work in hard gneiss, granite, or compact silicous limestone; 5 to 7 ft in tough compact hornblende; 3 to 5 in solid quartz; 8 to 9 in ordinary marble or limestone; 9 to 10 in sandstone; which, however, may vary within all these limits. When the hole is more than about 4 ft deep, two men are put to the drill. Artesian, and oil wells, in rock, are bored on the principle of the churn-drill.

The **jumper,** as now used, is much shorter than the churn-drill. One man (the *holder*) sitting down, lifts it slightly, and turns it partly around, during the intervals between the blows from about 8 to 12 lb hammers, wielded by two other laborers, the *strikers*. It can be used for holes of smaller diameters than can be made by the churn-drill; because the holder can more readily keep the cutting end at the exact spot required to be drilled. It is also better in conglomerate rock; the hard siliceous pebbles of which deflect the churn-drill from its vertical direction, so that the hole becomes crooked, and the tool becomes bound in it. The coal conglomerates are by no means hard to drill with a jumper. The jumper was formerly used for large deep holes also, before the churn-drill became established.

Either tool requires resharpening at about each 6 to 18 inches depth of hole, and the wear of the steel edge requires a new one to be put on every 2 to 4 days. With iron jumpers, the top also becomes battered away rapidly. As the hole becomes deeper, longer drills are frequently used than at the beginning. The smaller the diameter of the hole, the greater depth can be drilled in a given time; and the depth will be greater in proportion than the decrease of diam. Under similar circumstances three laborers with a jumper will about average as much depth as one with a churn-drill.

The **hand-drill,** in which the same man uses both the hammer and the short drill, is chiefly used for shallow holes of small diam. With it a fair workman will drill about as many feet of hole from 6 to 12 ins deep, and about $\frac{3}{4}$ inch diam, as one with a churn-drill can do in holes about 3 ft deep and 2 ins diam, in the same time. Only the jumper or the hand-drill can be used for boring holes which are horizontal, or much inclined.

Cost of quarrying stone. After the preliminary expenses of purchasing the site of a good quarry; cleaning off the surface earth and disintegrated top rock; and providing the necessary tools, trucks, cranes, &c; the total neat expenses for *getting out* the rough stone for masonry, per cub yard, ready for delivery, may be roughly approximated thus: Stones of such sizes as two men can readily lift, measured *in piles*, will cost about as much as from ¼ to ½ the daily wages of a quarry laborer. Large stones, ranging from ½ to 1 cub yd each, got out by blasting, from 1 to 2 daily wages per cub yd. Large stones, ranging from 1 to 1½ cub yds each, in which most of the work must be done by wedges, in order that the individual stones shall come out in tolerably regular shape, and conform to stipulated dimensions; from 2 to 4 daily wages per cub yard. The smaller prices are low for sandstone, while the higher ones are high for granite. Under ordinary circumstances, about 1⅓ cub yds of good sandstone can be quarried at the same cost as 1 of granite; or, in other words, calling the cost of granite 1, that of sandstone will be ¾; so that the means of the foregoing limits may be regarded as rather full prices for sandstone; rather scant ones for granite; and about fair for limestone or marble.

Cost of dressing stone. In the first place, a liberal allowance should be made for **waste.** Even when the stone wedges out handsomely on all sides from the quarry, in large blocks of nearly the required shape and size, from ⅛ to ¼ of the rough block will generally not more than cover waste when well dressed. In moderate-sized blocks, (say averaging about ½ a cub yard each,) and got out by blasting, from ¼ to ⅓ will not be too much for stone of medium character as to straight splitting. About the last allowance should also be made for well-scabbled rubble. The smaller the stones, the greater must be the allowance for waste in dressing. In large operations, it becomes expedient to have the stones dressed, as far as possible, at the quarry; in order to diminish the cost of transportation, which, when the distance is great, constitutes an important item—especially when by land, and on common roads.

A stonecutter will first take out of wind; and then fairly patent-hammer dress, about 8 to 10 sq ft of plain face in hard granite, in a day of 8 working hours; or twice as much of such inferior dressing as is usually bestowed on the beds and joints, and generally on the faces also of bridge masonry, &c, when a very fine finish is not required. In good sandstone, or marble, he can do about ¼ more than in granite. Of *finest* hammer finish, *granite*, 4 to 5 sq ft.

Cost of masonry. Every item composing the total cost is liable to much variation; therefore, we can merely give an example to show *the general principle* upon which an approximate estimate may be made; assuming the **wages of a laborer** to be $2.00 per day of 8 working hours; and $3.50 for a mason. **The monopoly of quarries** affects prices very much.*

Cost of ashlar facing masonry. Average size of the stones, say 5 ft long, 2 ft wide, and 1.4 thick, or two such stones to a cub yd. Then, supposing the stone to be granite or gneiss, the cost per cub yd of masonry **at such wages** will be,

Getting out the stone from the quarry by blasting, allowing ¼ for waste in dressing; 1⅓ cub yds, at $3.00 per yard	$4.00
Dressing 14 sq ft of face at 35 cts	4.90
" 52 " beds and joints, at 18 cts	9.36
Neat cost of the dressed stone at the quarry	18.26
Hauling, say 1 mile; loading and unloading	1.20
Mortar, say	.40
Laying, including scaffold, hoisting machinery, superintendence, &c	2.00
Neat cost	21.86
Profit to contractor, say 15 per ct	3.28
Total cost	25.14

Dressing will cost more if the faces are to be rounded, or moulded. If the stones are smaller than we have assumed, there will be more sq ft per cub yd to be dressed, &c.

If in the foregoing case, the stones be *perfectly* well dressed on all sides, including the back, the cost per cub yd would be increased about $10; and if some of the sides be curved, as in arch stones, say $12 or $14; and if the blocks be carefully wedged out to given dimensions, $16 or $18; thus making the neat cost of the dressed stone *at the quarry* say $28, $31, or $35 per cub yd.

---

* The blocks of granite for **Bunker Hill monument** averaging 2 cub yds each, were quarried by wedging, and delivered at the site of the monument, at a neat actual cost of $5.40 per cub yd; by the Monument Association; from a quarry opened by themselves for the purpose. The Association received no profit; their services being voluntary. The average contract offers for the same, were $24.30! The actual cost of getting out the rough blocks at the quarry was $2.70. Loading upon trucks at quarry, about 15 cts. Transportation 8 miles by railway and common road, $2.55. Total, $5.40. In 1825 to 1845; common unskilled labor averaging $1 per day.

The item of laying will be much increased if the stone has to be raised to great heights; or if it has to be much handled; as when carried in scows, to be deposited in water-piers, &c. Almost every large work presents certain modifying peculiarities, which must be left to the judgment of the engineer and contractor. The percentage of contractors' profit will usually be less on large works than on small ones.

Cost of ashlar facing masonry. If the stone be **sandstone** with good natural beds, the getting out may be put at $3.00 per cubic yard. Face dressing at 26 cts per sq ft · say $3.64 per cubic yd. Beds and joints 13 cts per sq ft, say $6.76 per cub yd. The neat cost, laid, $17.00.

And **the total cost of large well scabbled ranged sandstone masonry in mortar,** may be taken at about $10 per cub yd.

Cost of large scabbled granite rubble, such as is generally used as backing for the foregoing ashlar; stones averaging about ½ cub yd each ·

Labor at $1 per day.	Cost per cub yd of masonry.
Getting out the stone from the quarry by blasting, allowing ⅐ for waste in scabbling; $1\frac{1}{7}$ cub yds at $3.00	$3 43
Hauling 1 mile, loading and unloading	1 20
Mortar; (2 cub ft, or 1.6 struck bushels quicklime, either in lump or ground; and 10 cub ft, or 8 struck bushels of sand, or gravel; and mixing) ..	1 50
Scabbling; laying, including scaffold, hoisting machinery, &c.	2 50
Neat cost..........	8 63
Profit to contractor, say 15 per ct..........	1 30
Total cost	9 93

Common rubble of small stones, the average size being such as two men can handle, costs, to get it out of the quarry, about 80 cts per yard of pile, or to allow for waste, say $1.00. Hauling 1 mile, $1.00 It can be roughly scabbled, and laid, for $1.20 more; mortar as foregoing, $1.50. Total neat cost, $4.70, or, with 15 per ct profit, $5.40, *at the above wages for labor.*

With smaller stones, such as one man can handle, we may say, stone 70 cts, hauling $1; laying and scaffold tools &c, $1, mortar $1.50 Making the neat cost $4 20, or with 15 per ct profit, $4.83 Neat scabbled irregular range-work costs from $2 to $3 more per yd than rubble, according to the character of the stone &c. The laying of thin walls costs more than that of thick ones, such as abutments &c *

The cost of plain 8 inch thick ashlar facings for dwellings &c in Philada, in 1888, is about as follows per square foot showing, put up, including everything. Sand stone, $1.50 to $2 25. Pennsylvania marble, $2.50. New England marble, $2 75 to $3.25 Granite, $2.25 to $2.75. If 6 ins thick, deduct one-eighth part. **First class artificial stone** could be made and put up at one third the price. **North River blue stone flags,** 3 ins thick, for footwalks, put down, including gravel &c, 70 cts per sq foot. **Belgian street pavement,** with gravel, complete, $3.50 per sq yard in Eastern cities.

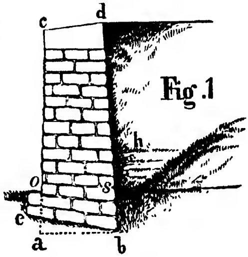
When dressed ashlar facing is backed by rubble, the expense per cub yard of the entire mass will of course vary according to the proportions of the two. Thus, if ashlar at $12 per yd, is backed by an equal thickness of rubble at $5, the mean cost will be ($12 + $5) ÷ 2 = $8.50; or if the rubble is twice as thick as the ashlar then ($12 + $5 + $5) ÷ 3 = $7.33, &c. **Such compound walls are weak** and apt to separate in time, as also walls of cut stone backed by concrete, or by brick; from unequal settlement of the two parts.

At times the contractor must be **allowed extra** in opening new quarries, in forming short roads to his work; in digging foundations; or for pumping or otherwise draining them, when springs are unexpectedly met with; for the centers for arches, &c, unless these items are expressly included in the contract per cub yd.

RETAINING-WALLS.

Art. 1. A retaining-wall is one for sustaining the pressure of earth, sand, or other *filling* or *backing*, deposited behind it after it is built; in distinction to a **face-wall,** which is a similar structure for preventing the fall of earth which is in its undisturbed natural position, but in which a vert or inclined face has been excavated. The earth is then in so consolidated a condition as to exert little or no lateral pres, and therefore the wall may generally be thinner than a retaining one.

This, however, will depend upon the nature and position of the strata in which the face is cut. If the strata are of rock, with interposed beds of clay, earth, or sand; and if they dip or incline toward the wall, it may require to be of far greater thickness than any ordinary retaining-wall; because when the thin seams of earth become softened by infiltrating rain, they act as lubrics, like soap, or tallow, to facilitate the sliding of the rock strata, and thus bring an enormous pres against the wall. Or the rock may be set in motion by the action of frost upon the clay seams; or, as sometimes occurs, by the tremor produced by passing trains. Even if there be no rock, still if the strata of *soil* dip toward the wall, there will always be danger of a similar result; and additional precautions must be adopted, especially when the strata reach to a much greater height than the wall. **A vertical wall** has both *c o* and *d s* vert.



Experience, rather than theory, must be our guide in the building of both kinds of wall. We recommend that the hor thickness *a b*, Fig 1, at the base of a vert or nearly vert retaining-wall *c d b a*, which sustains a backing of either sand, gravel, or earth, level with its top *c d*, as in the fig, should not be less than the following, in railroad practice, when the foundations are not more than about three feet deep.

When the backing is deposited loosely, as usual, *as when dumped from carts, cars, &c.*

Wall of cut-stone or of first-class large ranged rubble, in mortar.....a.b .... .35 *of its entire vert height* d b.
" *good common scabbled mortar-rubble, or brick.* .4 " " " "
" *well-scabbled dry rubble* .... .5 " " " "

With good masonry, however, we may take the height *d s* instead of *d b*, and then the above proportions of *d s* will give a sufficient thickness at the ground-line *o s*.

When the backing is somewhat consolidated in hor layers, each of these thicknesses *may* be reduced, but no rule can be given for this.

The **offset** *o e*, in front of the wall, is not included in these thicknesses.

When, however, the backing is a pure clean sand, or gravel, we should use only the full dimensions; inasmuch as the tremor, caused by passing trains, would neutralize any supposed advantage from ramming materials so devoid of cohesion. Such sand may be rammed with much advantage for the purpose of compacting it in foundations; but a diff principle is involved in that case. When it is done even with cohesive earths, with a view of saving masonry in retaining-walls, it is probable that the expense will generally be found quite equal to that of the masonry saved.

The base *a b* in Fig 1, is $\frac{4}{10}$ of the height *b d*. In the foregoing thicknesses at base, the back *d b* of the wall is supposed to be vert, and the face *c a* either vert, or battered (sloped or inclined backward) to an extent not exceeding about 1½ inches to a foot; which limit it is rarely advisable to exceed in practice, owing to the bad effect of rain, &c, upon the mortar when the batter is great. The base of a vert wall need not in fact be as thick as one with a battered face; but when the batter does not exceed 1.5 inches to a foot, the diff is very small. See Table, Art 7

Rem. 1. **A mixture of sand, or earth, with a large proportion of round bowlders** paving pebbles, &c, will weigh considerably more than the materials ordinarily used for backing, and will exert a greater pres against the wall; the thickness of which should be increased, say about one-eighth to one-sixth part, when such backing has to be used.

Rem. 2. The wall will be stronger if all the **courses of masonry be laid with an inclination inward,** as at *o e b*; especially if of dry masonry, or if time cannot be allowed (as it always should be, when practicable) for the mortar to set properly, before the backing is deposited behind it. The object of inclin-

ing the courses, is to place the joints more nearly at right angles to the direction fP, Figs 6, 7, and 8, of the pres against the back of the wall; and thus diminish the tendency of the stones to slide on one another, and cause the wall to bulge.

When the courses are hor, there is nothing to prevent this sliding, except the friction of the stones, one upon the other, when of dry masonry; or friction and the mortar, when the last is used. But if, as is frequently the case, (especially in thick and hastily built walls,) this has not had time to harden properly, it will oppose but little resistance to sliding. But when the courses are inclined, they cannot *slide*, without at the same time being *lifted up* the inclined planes formed by themselves. In retaining-walls, as in the abuts of important arches, the engineer should place as little dependence as possible upon mortar; but should rely more upon the position of the joints, for stability.

An objection to this inclining of the joints in *dry* (without mortar) walls, is that rain-water, falling on the battered face, is thereby carried inward to the earth backing, which thus becomes soft, and settles. This may be in a great measure obviated by laying the outer or face-courses hor, or by using mortar for a depth of only about a foot from the face. The top of the wall should be protected by a coping $c\,d$, Fig 1, which had better project a few ins in front. After the masonry has been built up to the surface of the ground, the foundation pit should be filled up, and it is well to consolidate the filling by ramming, especially in front of the wall.

The back $d\,b$ of the wall should be left rough. In brickwork it would be well to let every third or fourth course project an inch or two. This increases the friction of the earth against the back, and thus causes the resultant of the forces acting behind the wall to become more nearly vert; and to fall farther within the base, giving increased stability. It also conduces to strength not to make each course of uniform height throughout the thickness of the wall, but to have some of the stones (especially near the back) sufficiently high to reach up through two or three courses. By this means the whole masonry becomes more effectually interlocked or bonded together as one mass, and therefore less liable to bulge. Very thick walls may consist of a facing of masonry, and a backing of concrete.

Rem. 3. It is the pres itself of the earth against the back, that creates the friction, which in turn modifies the action of the pres, as the wt or pres of a body upon an inclined plane produces friction between the body and the plane, sufficient, perhaps, to prevent the body from sliding down it. A retaining-wall is *overthrown* by being made to revolve around its outer toe or edge e, Fig 1, as a fulcrum, or turning-point; but in order thus to revolve, its back must first plainly rise, and in doing so must rub against the backing, and thus encounter and overcome this friction. The friction exists the same, whether the wall stands firm or not, as in the case of the body on an inclined plane; the only diff is that in one case it *prevents* motion; and in the other only *retards* it.

C

O

Where deep freezing occurs the back of the wall should be sloped forwards for 3 or 4 ft below its top as at $c\,o$, which should be quite smooth so as to lessen the hold of the frost and prevent displacement.

a

Fig 2

Rem. 4. When the wall is too thin, it will generally fail by **bulging** outward, at about $\frac{1}{3}$ of its height above the ground, as at a, in Fig 2. A slight bulging in a new wall does not *necessarily* prove it to be actually unsafe. It is generally due to the newness of the mortar, and to the greater pres exerted by the fresh backing; and will often cease to increase after a few months. It need not excite apprehension if it does not exceed $\frac{1}{4}$ inch for each foot in thickness at a. See Remark 3, Art 7.

Art. 2. The young engineer need not in practice concern himself particularly about the PRECISE SP GRAV OF HIS BACKING, or about the ANGLE OF SLOPE at which it will stand; for the material which he deposits behind his wall one day, may be dry and incoherent, so as to slope at $1\frac{1}{4}$ to 1, the next lay rain may convert it into liquid mud, seeking its own level, like water; the next it may be ice, capable of sustaining a considerable load, as a vert pillar.

Moreover, he cannot foretell what may be the nature of his backing; for, as a general rule, this must consist of whatever the adjacent excavation may produce from time to time; sand to-day, rock to-morrow, &c. Retaining-walls are therefore usually built before the engineer knows the character of their backing; so that in practice, these theoretical considerations have comparatively but little weight. Theory, uncontrolled by observation and common sense, will lead to great errors in every department of engineering; but, on the other hand, no amount of experience alone will compensate for an ignorance of theory. The two must go hand-in-hand.

Again, **the settlement of the backing under its own wt,** aided by the tremors produced by heavy trains at high speed; its expansion by frost, or by the infiltration of rain; the hydrostatic pressure arising from the admission of the latter through cracks produced in the backing during long droughts; as well as its lubricating action upon it, (diminishing its friction, and giving it a tendency to slide,) &c, exert at times quite as powerful an overturning tendency as the legitimate theoretical pres does. The action of these agencies is gradual. Careful observation of retaining-walls year after year, will often show that their battered faces are becoming vertical. Then they will begin to incline outward; and eventually the wall will fail. Theory omits loads that may come on backing increasing its pres.

Assuming the theoretical views advanced by Professor Moseley to be correct as theories, the thicknesses which we have recommended in Art 1, for mortar walls, correspond to from 7 to 14 times; and for dry walls about 10 to 20 times, the pres assigned by him; and we do not consider ours greater than experience has shown to be necessary. See Table 3. Retaining-walls designed by good engineers, but in too close accordance with theory, (which assumes that a resistance equal to twice the theoretical pres is sufficient,) have failed; and the inference is fair that many of those which stand have too small a coefficient of safety.

The fact is, (or at least so it appears to us,) there must be defects in the theoretical assumptions of some of the most prominent writers who give practical rules on this subject. Thus Poncelet, who certainly is at their head, states that his tables, for practical use, give thicknesses of base for sustaining $1\frac{8}{10}$ times the theoretical pres; and this he considers amply safe. Yet, for a vert wall of cut granite, his base for sustaining dry sand level with the top, as in Fig 1, is .35 of the vert height; and for brick, .45. But the writer found that *when not subject to tremor*, a wooden model of a vert wall, weighing but 28 lbs per cub ft, and with a base of .35 of its height, balanced perfectly dry sand sloping at 1½ to 1, and weighing 89 lbs per cub ft.

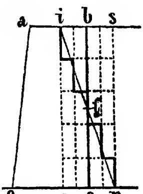


Fig 3

NOW, THE RESISTANCE OF SIMILAR WALLS, OF THE SAME DIMENSIONS, VARIES AS THEIR SPECIFIC GRAVITIES; and, since granite weighs about 165 lbs per cub foot, or 6 times as much as our model, it follows, we conceive, that a wall of that material, with a base of .35 of its height, must have a resistance of 6 times any *true theoretical* pres, instead of only $1\frac{8}{10}$ times; and that his brick wall must have about 5 times the mere balancing resistance. Our experiments were made in an upper room of a strongly built dwelling; and we found that the tremor produced by passing vehicles in the street, by the shutting of doors, and walking about the room, sufficed to gradually produce leaning in walls of considerably more than twice the mere balancing stability while quiet; and it appears to us that the injurious effects of a heavy train would be comparatively quite as great upon an actual retaining wall, supporting so incohesive a material as dry sand.

Since, therefore, Poncelet's wall is in this instance sufficiently stable for *practice*, it seems to us that his *theory*, which neglects the effect of tremors, &c, must be defective. He also gives $\frac{1}{5}$ of the height as a sufficiently safe thickness for a vert granite wall supporting *stiff earth;* but we suspect that very few engineers would be willing to trust to that proportion, when, as usual, the earth is dumped in from carts, or cars; especially during a rainy period. If deposited, and consolidated in layers, theory could scarcely assign any thickness for the wall; for the backing thus becomes, as it were, a mass of unburnt brick, exerting no hor thrust; and requiring nothing but protection from atmospheric influence, to insure its stability without any *retaining*-wall. It is with great diffidence, and distrust in our opinions, that we venture to express doubts respecting the assumptions of so profound an investigator and writer as Poncelet; and we do so only with the hope that the views of more competent persons than ourselves, may be thereby elicited. Our own have no better foundation than experiments with wooden and brick models, by ourselves; combined with observation of actual walls.

Art. 3. After a wall *a b c o*, Fig 3, with a vert back, has been proportioned by our rule in Art 1, it may be **converted into one with an offsetted back,** as *a i n o*. This will present greater resistance to overturning; and yet contain no more material. Thus, through the center *t* of the back, draw any line *i n*; from *n* draw *n s*, vert; divide *i s* into any *even* number of equal parts; (in the fig there are 4;) and divide *s n*, into *one more* equal parts; (in the fig there are 5.) From the points of division draw hor, and vert lines, for forming the offsets, as in the fig.

In the offsetted wall, the cen of grav is thrown farther back from the toe *o*, than in the other, thus giving it increased leverage and resistance; but within ordinary practical limits, the diff is very small; and since the triangle of supported earth is greater than when the back is vert, its pres is also greater, so that probably no appreciable advantage attends *that* consideration. **The increase of thickness near the base, diminishes, however, the leverage *v a*, Fig 8, of the pres *f* P, of the earth** against the back. The *center of pressure* of this pres is in both cases at ⅓ the vert height, measured from the bottom; and it is therefore plain that the farther back from the front it is applied, the shorter must *v a* become. Moreover, in the offsetted back, the *direction* of the pres becomes more nearly vert than when the back is upright. It is to these causes, rather than to the throwing back of the cent of grav, that the offsetted wall owes its increase of stability over one with a vert back.

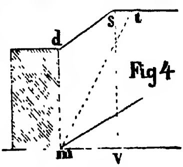

Fig 4

Art. 4. When, as in Fig 4, the backing is higher than the wall, and slopes away from its *inner* edge *d*, at the natural slope *d s*, of 1½ to 1, we are confident that the following thicknesses at base will at least be found *sufficien*

for vert walls with sand. They are deduced from the experiments just alluded to, and are but rude approximations, with no scientific basis We should not have inserted them, but for the fact that we know of no others for this case

The first column contains the vert height *s e*, of the earth as compared with the vert height of the wall: which latter is assumed to be 1, so that the table begins with backing of the same height as the wall, as in Fig 1 These vert walls may be changed to others, with battered faces, by Art 8; or without any such proceeding, their faces may be battered to any extent not exceeding 1½ inches to a foot, or 1 in 8, without sensibly affecting their stability, without increasing the base

TABLE 1. (Original)

Total height of the earth, compared with the height of the wall above ground.	Wall of Cut Stone, in Mortar.	Good Mortar Rubble, or Brick.	Wall of good dry Rubble. When the earth reaches above the top of the wall, as in Figs 4 and 5 the wall is **surcharged:** and the earth that is *above* the top, is called the SURCHARGE When the surcharge is carefully deposited above the wall, so as to slope back at a steeper angle than 1½ to 1, as say at 1 to 1, theory does not require the wall to be as thick. Notwithstanding Poncelet's high position, the writer cannot imagine that the base of a brick wall need be so great as 1½ times its height for any height of sand whatever.

Art. 6. On the theory of retaining-walls. Let *b c a m*, Fig 6, be such a wall, upholding backing or filling *c s m g*; the upper surf *c s* of which is hor, and level with the top *b c* of the wall; and let *m s* represent the nat slope of the earth which composes the backing; *m g* being hor.

Abundant experience on public works shows that this slope, whether for sand, gravel, or earth when dry, may be practically taken at 1½ to 1; that is, 1½ hor, to 1 of vert measurement; which corresponds to an angle *s m g* of 33° 41′ with the hor; which is also about the angle at which bricks and roughly dressed masonry begin to slide on each other. This angle, however, varies considera

bly, being greatly influenced by the degree of dryness, or dampness, of the material; so that moderately damp sand or earth will stand at a slope of 1 to 1, or at an angle of 45°. Whatever it may be, it is called THE ANGLE OF NAT SLOPE of the material under consideration. In theoretical calculations for walls, it is safest to assume (as we have done throughout) that the backing is perfectly dry, since

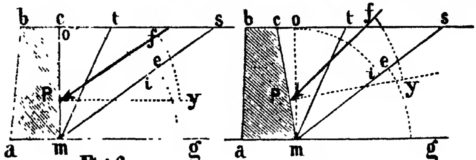

Fig. 6 Fig. 7

its pres is then greatest; unless it be supposed to be so wet as to possess some degree of fluidity. The triangle *c m s* of earth above the nat slope *m s*, tends to slide down said slope, but is prevented from so doing by the wall.

It is assumed in all cases, that the wall is secured from *sliding* along its base, Art 9, that it is thick enough to prevent failure by *bulging*, and that it will fail only by *overturning*, by rotating around its toe, *a*, as a fulcrum. The thickness necessary to insure safety against the last will also be sufficient to prevent bulging. Now referring only to Fig 6 with a vert back, if the angle *o m s*, contained between the natural slope *m s*, and a vert line *m o*, drawn from the inner bottom edge *m* of the wall, be divided by a line *m t*, into two equal angles, *o m t*, *t m s*, then the angle *o m t* is called THE ANGLE, and *m t* THE SLOPE, OF MAXIMUM PRESSURE. The triangular prism of earth, of which *o m t* is a section, or an end view, is called THE PRISM OF MAX PRES; because, if considered as a wedge acting against the back of the wall, it would produce a greater pres upon it than would the entire triangle *c m s* of earth, considered as a single wedge. For although the last is the heaviest, yet it is more supported by the earth below it. Calculation shows that if we consider the earth *o m s* to be thus div into wedges by *any* line *m t*, the wedge that will press most against the wall is that formed when *m t* divides the angle *o m s*, or the arc *o i*, into two equal parts. But see Art 11.

Since *m g* is hor, and *m o* vert, the two form an angle of 90°; consequently the angle of max pres is plainly found by taking the angle *s m g* of nat slope from 90°, and div the rem by 2. Thus a nat slope of 1½ to 1, or 33° 41′, taken from 90°, leaves 56° 18′, and $\frac{56° 18'}{2}$ = **28° 9′, the corresponding angle o m t of max pres.**

For ease of calculation, only one foot of the *length* of the wall, and of its backing, is usually considered. The number of *cub ft* of wall, or of backing, is then equal to that of the *square* feet in their respective profiles, or cross-sections.

Now, according to Moseley, if we assume the particles of earth composing the backing to be perfectly dry, and devoid of cohesion, (or tendency to stick to each other,) which is very nearly the case in pure sand; and if we suppose the wall to be suddenly removed, then the triangle of earth *c m t*, comprised between the slope *m t* of max pres, and the vert back *c m* of the wall, Fig 6, would slide down, under the influence of a force which may be represented by *y* P, acting in a *direction y* P, at right angles to the face *c m* of the triangle of earth; (or in other words, at right angles to the back of the vert wall,) its *center of force* being at P, distant ⅓ way between *m* and *c*, measured from the bottom; and its *amount* equal to either of the following:

No 1. $\frac{\textit{Perp pres}}{\text{y P}} = \frac{\textit{Wt of the triangle of earth}\ \text{c m t} \times \text{o t}}{\textit{vert depth}\ \text{o m}}$; or

No 2. $\frac{\textit{Perp pres}}{\text{y P}} = \frac{\textit{Wt of a single cub ft of the backing} \times \textit{sq of}\ \text{o t}}{2.}$

See Art. 11.

In view of the great uncertainty involved in the matter of the actual pressure of earth against retaining-walls in practice (see Art 2,), and in order to furnish a simple rule which, although entirely unsupported by theory, is still (in the writer's opinion) sufficiently approximate for ordinary practical purposes, we shall assume that No 1 of the two foregoing formulas applies near enough to walls **with inclined backs *c m*,** also, as Figs 7 and 8, (precisely as they are lettered,) at least **until the back of the wall inclines forward as much as 6 ins hor, to 1 foot vert,** or at an angle *c m o* of 26° 34′. **What follows on retaining-walls will involve this incorrect assumption, and must be regarded merely as giving safe approximation.**

Some appear to assume this perp pres to be the only one acting against the back of the wall; and hence arrive at erroneous practical conclusions. For when, in order to prevent this force from causing the triangle of earth to slide, we place a retaining-wall in front of it, then, instead of *motion*, the force will produce *pres* of the earth against the wall, causing *friction* between the pressed surfaces of the

earth and wall. That is, if a wall were to begin to overturn around its toe *a* as a fulcrum, its back *c m* must of course rise, and in so doing must rub against the earth filling in contact with it; and this rubbing would evidently act to *impede* the overturning. So long as the wall does not move, the same friction assists in *preventing* overturning. To ascertain the amount and effect of this friction, let *y* P, Fig 8, represent *by scale* the force perp to the back *c m*; and supposed to have been previously calculated by the foregoing formula No 1 Make the angle *y* P *f* equal to the angle of wall friction,* draw *y f* at right angles to *y* P, or parallel to *m c*; make P *x* equal to *y f*, and complete the parallelogram P *y f x*. Then will *x* P represent by the same scale, **the amount of the friction against the back of the wall.**

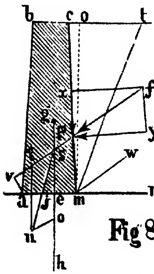

Fig 8.

Hence we have acting at P, two forces; namely, the perp force *y* P, and the friction *x* P; consequently, by comp and res of force, the diag *f* P of the parallelogram P *y f x*, if measured by the same scale, will give us the amount of their resultant; **which is the approx single theoretical force, both in amount and in direction, which the wall has to resist,** including the wall friction.

But this force, *f* P, is also always equal to the perp force *y* P, mult by the nat sec of the angle *y* P *f* of the wall friction; (or divided by its nat cosine) and of course may be ascertained thus:

$$\text{Approx theoretical pres f P} = \frac{\text{wt of triangle c m t} \times \text{o t} \times \text{nat sec of angle y P f of wall friction}}{\text{vert depth o m}} = \frac{\text{wt of c m t} \times \text{o t}}{\text{cos y P f} \times \text{o m}}$$

Or finally, if it is assumed, as we do throughout, that the earth is perfectly dry (inasmuch as its pressure is then the greatest) and that the angles of nat slope, and of wall friction are then each 33° 41′ or 1.5 to 1, then in Figs 6, 7 and 8, if the angle *c m o* between the back *c m* and the vert *o m* does not exceed about 26° 34′ we may assume

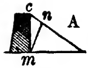
$$\textbf{Approx theoretical pres f P} = \textbf{wt of triangle c m t} \times .643$$

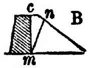
which includes the action of the friction of the earth against the back of the wall.

Rem. 1. **When the back of the wall is offsetted or stepped,** as in Fig 3, instead of being simply battered, as in Figs 7 and 8, the direction of the pres of the earth will be the same as if the back had the batter *i n*.

Rem. 2. **Now to find both the overturning tendency of the earth,** and the resistance of the wall against being overturned around its toe *a* as a fulcrum, first find the cen of grav *g* of the wall, and thru it draw a vert line *gh*. Prolong *f*P toward *v* and draw *av* perp to it By any scale make *so* = wt of wall, and *st* = calculated pres *f*P. Complete the parallelogram *s t n o*, and draw its diagonal *sn*, which will be the resultant of the pres *f*P and of the wt of the wall, and should for safety be such that *aj* be not *less* than about one-fifth of *am*, *even with best masonry and unyielding soil*. Otherwise the great pressure so near the toe *a* may either fracture the wall or compress the soil near that point so that the wall will lean forward. In walls built by our rule, Art 1, or by table, p 610, *aj* will be more than one-fifth of *am*. The pres *f*P if multiplied by its leverage *av* will give the moment of the pres about *a*; and the wt of the wall multiplied by its leverage *ea* will give that of the wall. The wall is safe from overturning in proportion as its moment exceeds that of the pres. It is assumed to be safe against *sliding*, *breaking*, or *settling* into the soil.

* **This angle of wall friction** is that at which a plane of masonry must be inclined to the horizontal so that dry sand or earth would slide down it. It is about the same as the nat slope, or 33° 41′, or 1.5 to 1; and its nat secant is 1.202, and its nat cos .832.





Rem. 4. If the earth slopes downward from C, as at A or B, instead of being hor as in Figs 6, 7, 8, use the wt of the earth *c m n* instead of *c m t*, *m n* being the slope of max pressure. In A the point of application will still be at P (at one-third of *m c*) as in 6, 7, 8; but in B it will be a little higher as explained below for Fig 9.

Surcharged walls are those in which the earth backing extends above the tops of the walls.

According to theory, when as in Fig 9, there is a surcharge *v c k* of backing, sloping away from *c* at its natural slope *c v*, the max pres against the wall is attained when the earth reaches to the level of *d*, where the slope *m t d* of max pres intersects the face of the nat slope *c v*; so that if afterward the earth is raised to *v*, or to any greater height, no additional pres is thereby thrown against the back of the wall. So also if the earth slopes from *b*, or from between *c* and *b*, except that then the slope *m d* of max pres must extend up to meet this other slope.

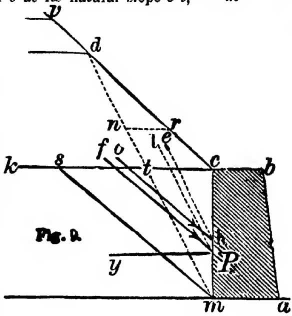


Fig. 9.

The approximate amount of the oblique pres, when the wall is surcharged, (as in any of the Figs 4, 5, 9,) may be found on the same principle as when the earth is level with its top; namely, instead of the *triangle c m t* of earth, Figs 6, 7, 8, 9, find the wt of *all* the earth *d s m t*, Fig 4, *d m t r*, Fig 5, or *c d m*, Fig 9 (if the surcharge reaches to *d* or *v*, or higher), between the slope *m d*, Fig 9, *m t*, Figs 4 and 5, of max pres, the back of the wall, and the front slope; omitting any which, like *d c n*, Fig 5, rests on the top of the wall (and thus adds to its stability) when the slope starts in front of *c*. Having found this weight, then for dry backing the

$$\left.\begin{array}{r}\textbf{Pressure}\\ \textbf{approximately}\end{array}\right\} = \textbf{Wt of the earth} \times .643,$$

including the action of the friction of the earth against the back of the wall; near enough (in the writer's opinion) for practical purposes in so uncertain a matter; but essentially empirical.

The direction of the pressure thus found will be the same as when the earth is level with the top *b c*; namely, as in Figs 6 and 7, first draw a line, as P *y*, perp to the back *c m*, whether vert or inclined. Then draw another line, as P *f*, making the angle *y* P *f* = the angle of wall friction, which we all along assume to be 33° 41′, or 1.5 to 1. Then P *f* will give the direction of the pressure. But its point of application will not always be at P (one-third of the height of the wall above *m*) as heretofore; for in all cases it will be at that point P, or at some **higher** one as *h*, where the back is cut by a line *l* P or *e h*, Fig 9, drawn from the cen of grav of the sustained earth (omitting any that rests immediately on the top *b c*), and parallel to the slope *m d* of max pres; and such a line will strike at one-third the height of the wall only when the sustained earth *t c m* or *d c m* **forms a complete triangle**, one of whose angles is at the inner top edge *c* of the wall. In all other cases said line for a surcharge will strike above P.

Art. 7. On page 603, Fig 1, we recommend that the base *o s* at the ground-line of well built **vertical** walls should not be less than .35, or .4, or .5 of the height *d s* above said line, depending on the kind of masonry. But a wall with a **battered** (inclined) front or face as found by Art 8, (by which the following table was prepared), will be as strong, and at the same time contain less masonry than a vert wall, although the battered one will have the thickest base *o s*.

Table 3, of thicknesses at base *o s*, Fig 1, and at top *c d*, of walls with battered faces, so as to be as strong as vertical ones which contain more masonry.

For the cub yds of masonry above *o s* per foot run of wall, mult the **square** of the vert height *d s* by the number in the column of cub yds. Then add the foundation masonry below *o s*.

(Original.)

All the walls below have the same strength as a vert one whose base *o s*, fig 1 = .35 of its ht *d s*.				All the walls below have the same strength as a vert one whose base *o s*, fig 1 = .4 of its ht *d s*.			All the walls below have the same strength as a vert one whose base *o s*, fig 1 = .5 of its ht *d s*.

Moseley and others quote Gadroy, for a DRY SAND SLOPING AT 21°. It would be better to cease from circulating such evident mistakes. Dry sand will stand at no less angle for a *savant* than for anybody else. For practical purposes, we may say that dry sand, gravel and earths, slope at 33° 41′ or 1½ to 1; as abundant experience on railroad embkts proves. Poncelet gives tables for walls to support dry earth sloping at 1 to 1, or 45°, but as we do not believe in the existence of such earth, we omit such tables. Sand gravel and earths may be moistened to diff degrees, so as to stand at any angle between hor and vert, and by moistening and ramming the earths may be converted into compact masses, exerting little or no pres, and may even so continue after they become dry; being then, in fact, a kind of air-dried brick. It is sometimes difficult to know whether earth or sand is perfectly dry or not; and an *exceedingly* small degree of moisture will cause them to stand at 1 to 1, in *small heaps*, such as have probably been observed by the authorities on the subject. The writer found that fine sand from the sea-shore, and under cover, would stand at 1½ to 1 during warm dry weather, and at 1 to 1 when the air was damp. Yet no diff whatever in its degree of moisture was perceptible to the feeling. Its susceptibility to dampness was of course owing to salt. A few handfuls of dry earth may perhaps be coquetted into standing at 1 to 1 on a table, but so far as our observation extends, when it is dumped in large quantities from carts and wheelbarrows, its slope is about 1½ to 1; and this we consider the proper one to be used in practical calculations, where safety is the consideration of paramount importance.

The less the nat slope, the greater is the pres: and since the slope is least when the backing is perfectly dry, (omitting of course its condition when so absolutely *wet* as to become partially fluid,) we have, on the score of safety, confined our tables to dry backing. As stated in Art 1, we cannot recommend dimensions less than those there given, when we consider the rough treatment to which masonry is exposed on public works.

In carrying a road along dangerous precipices, we should rather be tempted at times to make thicker walls. We imagine, for instance, that the centrifugal force of a heavy train, whirling around a sharp curve, convex on the dangerous side, should not be overlooked in designing walls for such localities. This force is hor; and is applied near the top of the wall: and, consequently, its leverage may be considered as equal to the height; whereas the theoretical pres of the earth is oblique; and is applied at ⅓ of the height from the bottom; so that its leverage about the toe of the wall is very short. Moreover, the simple *weight* of the train, produces pres against the wall; as well as that of the backing. All such considerations are omitted by theorists. The dangerous pres caused by tremors, &c, cannot be

assumed to be applied at $\frac{1}{3}$ of the height from the bottom; nor indeed, can it be calculated at all.

REM. 2. **Wharf walls** are an instance where the thickness should be increased, notwithstanding that the pres of the water in front helps to sustain them. The earth behind such walls, is not only liable to be very heavily loaded when vessels are discharging; but is apt to become saturated with water, especially below low-water level; and thus to exert a very great pres against the walls. Moreover, the water gets under the wall; and by its upward pressure virtually reduces its weight, and consequently its stability. The same cause of course diminishes the friction of the wall upon its base. Such walls are, therefore, very liable to slide, if the foundation is smooth, and horizontal; and have done so even when the foundation had a considerable inclination backward, as in Fig 1. See Art 9.

REM. 3. A retaining-wall is usually in greater danger for a few months after its completion, than after time has been allowed for the mortar to harden perfectly; and for the backing to settle. When there are suspicions of the safety of a new wall, it would be well to place strong temporary shores against it, at about $\frac{1}{4}$ to $\frac{1}{2}$ of its height above ground. In some cases, permanent buttresses of masonry may be built for the purpose. They should be well bonded into the wall.

REM. 4. The pres of the earth backing will be much reduced, if the first few feet of its height be made up in thin hor layers, to be consolidated by being used by the masons instead of scaffolding; as shown at *h*, Fig 1. Frequently this can be done without inconvenience; and at very trifling cost.

Art. 8. To change a vert retaining-wall, into one with a battered face, which shall present an equal resistance against overturning; although requiring less masonry. This is sometimes termed a **transformation of profile.** (Original.)

Let *a b o i*, Fig 10, be the vert wall. Mult its base *o i*, by 1.225; (1.22475 is nearer;) the prod will be the base *o e*, of a triangular wall *b o e*, possessing the same stability; and yet not requiring much more than half the masonry of the vert one. See Rem 1. This being done, suppose a wall to be desired with a face batter, of say 3 ins to a ft; or 1 in 4. From the point *n*, where the face of the triangular wall intersects that of the vert one, step off vert any 4 short equal spaces; and from the upper one *m*, step off one space hor, to *v*. Through *v* and *n* draw the dotted line *s t*, which evidently will batter 1 in 4. Then is *b s t o* approximately the reqd wall, but a little thicker than necessary. To reduce it, from *t* draw the dotted line *t b*. Mark the point *c*, where this line intersects the face *a i*, of the vert wall; and through *c* draw *d l*, parallel to *s t*. Then is *b d l o* the reqd wall. Our fig is drawn in an exaggerated manner, so as to avoid confusion in the lines. The base *o e* of the triangular wall, would not in reality be near so great as it is represented.

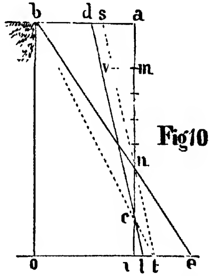

Fig 10

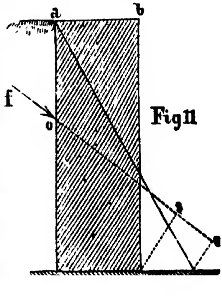
It will be observed that as the base increases, the quantity of masonry diminishes.

REM. 1. **The battered wall will in fact be safer than the vert one.** The battered wall has the same moment of stability as the vert one; and the pres of the earth against it also remains unchanged, but the *moment* or *tendency* of the pres to upset the wall has become less. For let *a b m n*, Fig 11, represent a vertical wall; and *f o* the *amount* and direction of pres behind it. (For ease of illustration, we have placed *o above* the true cen of pres of the earth filling, which would be at one-third of *a n* above *n*.) Now, the leverage with which this pres tends to overturn the wall around its toe *m*, is the dist *m s*, measured from the toe or fulcrum *m*, and at right angles to the direction *f o s c* of the pres, and this leverage mult by the force *f o*, gives the overturning tendency or moment of said force. See "Moments and leverage." Again, let *a n y*, represent a triangular wall of the same stability as the other, as found by our rule. Here we still have the same amount *f o*, and direction *f o s c*, of pres force against the wall; but it now acts to overturn the wall *a n y* around the toe *y*; and therefore, with the reduced leverage *y c*. Consequently, its overturning tendency is less than before. Therefore, in ordinary language, we may say that the wall is stronger than before, although its moment of stability, or standing tendency, has in itself undergone no change. If the pres *f o* against the vert back were hor, as in the case of water, then its leverage would evidently be the same in both walls; and the proportion between the overturning moment of the pres, and the moments of stability of the two walls, would be constant.



REM 2. In attempting to reduce the masonry by adopting a wall, *o b e*, Fig 10, of a triangular section; or of one nearly approaching a triangle, special attention should be given to the quality of the masonry near the thin toe *e*; which will otherwise be apt to crack, or fail under the pres.

REM 3. MOREOVER, WHEN COMMON MORTAR IS USED WITHOUT AN ADMIXTURE OF CEMENT, which it neve should be, in retaining-walls, where durability is an object, a great batter is obje tionable; inasmuch as the rain, combined with frost, &c, soon destroys the mor tar. In such cases, therefore, the batter should not exceed 1 or 1½ ins to a ft; an even then, at least the pointing of the joints, and a few feet in height of bot the upper and the lower courses of masonry, should be done with cement, o cement-mortar. We have observed a most marked diff in the corrosion of the mor tar, where, in the same walls, with the same exposure, one portion has been buil with a vert face; and another with a batter of but 1½ inch to a foot. Commo mortar will never set properly, and continue firm, when it is exposed to mois ture from the earth. This is very observable near the tops and bottoms o abuts, retaining-walls, &c; the lime-mortar at those parts will generally b found to be rendered entirely worthless. A profile somewhat like Fig 12, ma at times prove serviceable, instead of the triangular. This is the form of th Gothic buttress; which probably had its origin in the cause just spoken of.

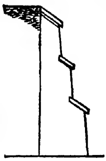


Fig 12

Art. 9. A retaining-wall may slide, withou losing its verticality; and, indeed, without any dange of being overturned. This is very apt to occur if it is built upo a hor wooden platform; or upon a level surf of rock, or clay without other means than mere friction to prevent sliding. This may be obviate by inclining the base, as in Fig 1; by founding the wall at such a depth as to pro vide a proper resistance from the soil in front; or in case of a platform, by securing one or more lines of strong beams to its upper surf, across the direction in whic sliding would take place. On **wet clay,** friction may be as low as from .2 t ⅓ the weight of the wall; on dry earth, it is about ½ to ⅝; and on sand or gravel about ⅝ to ¾. The friction of masonry on a woode platform, is about $\frac{6}{10}$ of the wt, if dry; and ¾ if wet

Fig 13

Counterforts, shown in plan at *c c c*, Fig 13, consist i an increase of the thickness of the wall, *at its back*, at regular inte vals of its length. We conceive them to be but little better than waste of masonry. When a wall of this kind fails, it almost in variably separates from its counterforts; to which it is connecte merely by the adhesion of the mortar; and to a slight extent, by th bonding of the masonry. The table in Art 7 shows that a very small addition to the base of a wall, i attended by a great increase of its strength; we therefore think that the masonry of counterfort would be much better, and more cheaply employed in giving the wall an additional thickness, alon its entire length; and for the lower third of its height. Counterforts are very generally used i retaining-walls by European engineers; but rarely, if ever, by Americans.

Buttresses are like counterforts, except that they are placed *in front* of a wall instead of be hind it; and that their profile is generally triangular, or nearly so. They greatly increase its strength but, being unsightly, are seldom used, except as a remedy when a wall is seen to be failing.

Land-ties, or long rods of iron, have been employed as a makeshift for upholding weak re taining-walls. Extending through the wall from its face, the land ends are connected with anchor of masonry, cast-iron or wooden posts; the whole being at some dist below the surface.

Retaining walls with curved profiles are mentioned here merely to cau tion the young engineer against building them. Although sanctioned by the practice of some hig authorities, they really possess no merit sufficient to compensate for the additional expense and trou ble of their construction.

Art. 10. Among military men, a retaining-wall is called a **revetment.** When th earth is level with the top, a **scarp revetment;** when above it, a **counterscar** revetment, or a *demi-revetment*. When the face of the wall is battered, a *sloping;* and when the bac is battered, a *countersloping* revetment. The batter is called the **talus.**

Art. 11. The pres against a wall Fig 6, from sand etc level with its top, is not diminished by reducing the quantity of sand, until its top width *c s* becomes less than that (*c t*) pertaining to the angle *c m t* of maximum pres. The pres then begins to di minish, but in practice *the diminution is not appreciable until the width is reduced to* about one sixth of that (*c s*) pertaining to the angle *c m s* of natural slope, or about half of *c t*. The pres then begins to decrease rapidly as the width is further reduced.

Table 4, of contents in cub yards for each foot in length of retaining-walls, with a thickness at base equal to .4 of the vert height if the back is vert. If the back is stepped according to the rule in Art 3, the proportionate thickness at base will of course be increased. Face batter, 1½ inches to a foot; or ⅛th of the height. Back either vert, or stepped according to the rule in Art 3, Fig 3. The strength is very nearly equal to that of a vert wall with a base of .4 its height. Experience has proved that such walls, when composed of well-scabbled mortar rubble, are safe under all ordinary circum stances for earth level with the top. Steps or offsets, *o c*, at foot, Fig 1, are not here included.

STONE BRIDGES.

Art. 1. In an arch *s t s*, Fig 1, the dist *e o* is called its **span**; *i a* its **rise**; *t* its **crown**; its lower boundary line, *e a o*, its **soffit**, or **intrados**; the upper one, *r t r*, its **back**, or **extrados.** The terms soffit and back are also applied to the entire lower and upper curved *surfaces* of the whole arch. The ends of an arch, or the showing areas comprised between its intrados and extrados, are its **faces**; thus the area *s t s a* is a face. The inclined surfaces or joints, *r e*, *r o*, upon which the *feet* of the arch rest, or from which the arch *springs*, are the **skewbacks.** Lines level with *e* and *o*, at right angles to the faces of the arch, and forming the lower edges of its feet, (see *n n*, Fig 2½,) are the **springing lines**, or **springs.** The blocks of which the arch itself is composed, are the **arch-stones**, or **voussoirs.** The center one, *t a*, is the **keystone**; and the lowest ones, *s s*, the **springers.** The term *archblock* might be substituted for voussoir, and like it would apply to brick or other material, as well as to stone. The parts *t r*, *t r*, are the **haunches**; and the spaces *t r l*, *t r b*, above these, are the **spandrels.** The material deposited in these spaces is the **spandrel filling**; it is sometimes earth, sometimes masonry; or partly of each, as in Fig 1.

In large arches, it often consists of several parallel SPANDREL-WALLS, *l l*, Fig 2½, running lengthwise of the roadway, or astraddle of the arch. They are covered at top either by small arches from wall to wall, or by flat stones, for supporting the material of the roadway. They are also at times connected together by vert cross-walls at intervals, for steadying them laterally, as at *t t*, Fig 2½. The parts *g p e n*, *g p o n*, Fig 1, are the ABUTMENTS of the arch; *e n*, *o n*, the *faces*; *g p*, *g p*, the backs; and *p n*, *p n*, the *bases* of the abuts. The bases are usually widened by *feet*, *steps*, or *offsets*, *d d*, for distributing the wt of the bridge over a greater area of foundation; thus diminishing the danger of settlement. The distance *t a* in any arch-stone, is called its *depth*.

The only arches in common use for bridges, are the circular, (often called segmental); and the elliptic.

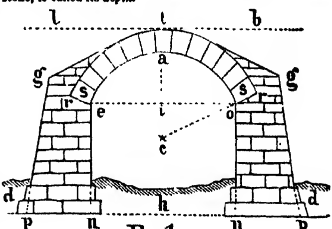

Fig 1

Art. 2. To find the depth of keystone for first-class cut-stone arches, whether circular or elliptic.*

Find the rad *c o*, Fig 1, which will touch the arch at *o*, *a*, and *e*. Add together this rad, and *half* the span *o e*. Take the sq rt of the sum. Div this sq rt by 4. To the quot add $\frac{2}{10}$ of a ft. Or by formula,

* Inasmuch as the rules which we give for arches and abuts are entirely original and novel, it may not be amiss to state that they are not altogether empirical, but are based upon accurate drawings

$$\text{Depth of key in feet} = \frac{\sqrt{\text{Rad} + \text{half span}}}{4} + 0.2 \text{ foot.}$$

For second-class work, this depth may be increased about ⅛th part; or **for brick or fair rubble,** about ⅓rd. See table of Keystones.

In large arches it is advisable to increase the depth of the archstones toward the springs; but when the span is as small as about 60 to 80 or 100 feet, this is not at all *necessary* if the stone is good; although the arch will be stronger if it is done. In practice this increase, even in the largest spans, does not exceed from ¼ to ½ the depth of the key; although theory would require much more in arches of great rise.

REM. **To find the rad** $c\,o$, whether the arch be circular or elliptic. Square *half* the span $e\,o$. Square the whole rise $i\,a$. Add these squares together; div the sum by *twice* the rise $i\,a$. Or it may be found near enough for this purpose by the dividers, from a small arch drawn to a scale.

Amount of pressure sustained by archstones. In bridges of the same width of roadway; if all the other parts bore to each other the same proportion as the spans, the *total* pres would increase as the squares of the spans, while the pressure *per square foot* would increase as the spans. But in practice the depth of the archstones increases much less rapidly than the span; while the thickness of the roadway material, and the extraneous load per sq ft, remain the same for all spans. Hence the *total* pressures, at key and at spring, increase *less* rapidly than the *squares* of the spans; but *more* rapidly than the simple *spans;* as do also the pressures *per square foot.* Thus in two bridges of the same width, but with spans of 100 and 200 ft, with depths of archstones taken from our table and uniform from key to spring; supposed to be filled up solid with masonry of 160 lbs per cub ft, to a level of about 15 inches above the crown, (including the stone paving of the roadway); with an extraneous load of 100 lbs per sq ft; the pressures will be approximately as follows:

	Span 100 ft.				Span 200 ft.			
	AT KEY.		AT SPRING.		AT KEY.		AT SPRING.	
	For 1 ft in width of its entire depth.	Per sq ft.	For 1 ft in width of its entire depth.	Per sq ft.	For 1 ft in width of its entire depth.	Per sq ft.	For 1 ft in width of its entire depth.	Per sq ft.
Rise.	Tons.	Tons.	Tons.	Tons.	Tons.	Tons.	Tons	Tons.
⅙	42¾	13¾	58	18¾	126	29¼	179	42
⅕	36¾	12¼	57	19	112	27¾	181	44
¼	31¼	11	57½	20	97	24½	188	47½
⅓	25	9	61½	22½	80¼	21	207	54¾
½	18	6¾	67½	25	67¼	15½	230	61½

It will be seen that with the same span, the pres at the key becomes less, while that at the spring becomes greater, as the rise increases. Also that when the archstones are of uniform depth, the pres at either spring of a semicircular arch is about 4 times as great as at the key; whereas when the rise is but one-sixth of the span, the pres at spring averages but about one-third greater than at the key. These proportions vary somewhat in different spans.

The greater pres per sq ft at the springs may be reduced by increasing the depth of the archstones towards the springs. This however is not *necessary* in moderate spans, inasmuch as good stone will be safe even under this greater pres.

By using parallel spandrel walls, see Fig 2½, or by partly filling with earth instead of masonry, the pres on the archstones may be diminished, say, as a rough average, about ⅓ part.

and calculations made by the writer, of lines of pres, &c, of arches from 1 to 300 ft span, and of every rise, from a semicircle to $\frac{1}{16}$ of the span. From these drawings he endeavored to find proportions which, although they might not endure the test of strict criticism, would still apply to all the cases with an accuracy sufficient for ordinary practical purposes.

Table 1. Of some existing arches, with both their actual and their calculated depths (by our rule) of keystone. Where two depths are given in the column of keys the smallest is for first-class cut-stone, and the largest for good rubble, or brick. Those also which are not specified are of first-class cut-stone. C stands for circular, E for elliptic. For 2d class work, add about 1/8th part, and for brick, or fair rubble, about 1/4th

Arch of granite. The centers rested (for four months) on sand in 16 cylinders, 1 ft diameter, 1 ft high, of $\frac{1}{32}$-inch sheet iron. The unloaded arch settled 15 millimeters (0.59 inch) on striking the centers. The additional settlements under extraneous loads were as follows:

Extraneous load.	Kilograms.	Pounds.	Increase of settlement. Millimeters.	Increase of settlement. Inches.
Distributed	367000	809000	21	0 8
Center..	4975	11000	0.3	0.012
Distributed	132600	292000	1.2	0.047

With the distributed load of 367000 kilog, a load of 4975 kilog, falling 0.3 m (11.8 ins) on key, caused vibrations of 2.8 mm (0.11 inch). *Annales des Ponts et Chaussées,* 1866 *Part* 2, 1868 *Part* 2.

The arch on the BOURBONNAIS RAILWAY, is probably the boldest:* and THE CABIN JOHN ARCH, by Capt, now Gen'l M. C. Meigs, U S Army, the grandest stone one in existence. PONT-Y PRYDD, in Wales, is a common road bridge, of very rude construction, with a dangerously steep roadway. It was built entirely of rubble, in mortar, by a common country mason, in 1750, and is still in perfect condition. Only the outer, or *showing* arch-stones, are 2.5 ft deep, and that depth is made up of two stones. The inner arch-stones are but 1 5 ft deep; and but from 6 to 9 inches thick. The stone quarried with tolerably fair natural beds, and received little or no dressing in addition The bridge is a fine example of that ignorance which often passes for boldness. PONT NAPOLEON carries a railroad across the Seine at Paris. The arches are of the uniform depth of 4 ft, from crown to spring. They are composed chiefly of *small rough quarry chips*, or *spawls*, well washed, to free them from dirt and dust; and then thoroughly bedded in good cement, and grouted with the same It is in fact an arch of cement-concrete. The PONT DE ALMA, near it, *and built in the same way*, has elliptic arches of from 126 to 141 ft span; with rises of $\frac{1}{5}$ the span. Key 4.9 ft. These two bridges, considering the want of precedent in this kind of construction, on so large a scale, must be regarded as very bold; and as reflecting the highest credit for practical science, upon their engineers, Darcel and Couche Some trouble arose from the unequal contraction of the different thicknesses of cement. They show what may be readily accomplished in arches of moderate spans, by means of small stone, and *good hydraulic cement* when large stone fit for arches is not procurable. In Pont Napoleon the depth of arch is less than our rule gives for second class cut-stone.

Art. 3. The keystones for large elliptic arches by the best engineers, are generally made about ⅓ part deeper than our rule requires, or than is considered necessary for circular ones of the same span and rise; in order to keep the line of pres well within the joints; although the elliptic arch, with its spandrel filling, has slightly less wt; and that wt has a trifle less leverage than in a circular one; and consequently it exerts less pres both at the key, and at the skew-back. See London, Gloucester, and Waterloo bridges, in the preceding table.

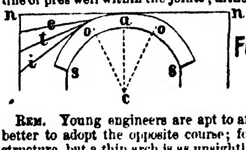

Fig. 1½

REM. Young engineers are apt to affect shallow arch-stones; but it would be far better to adopt the opposite course; for not only do deep ones make a more stable structure, but a thin arch is as unsightly an object as too slender a column. According to our own taste, arch-stones fully ⅓ deeper than our rule gives for first-class cut stone, are greatly to be preferred when appearance is consulted. Especially when an arch is of rough rubble, which costs about the same whether it is built up as arch, or as spandrel filling, it is mere folly to make the arches shallow Stability and durability should be the objects aimed at; and when they can be attained even to excess, without increased cost, it is best to do so.

* Built like that at Souppes.

Table 2. Depths of keystones for arches of first-class cut stone, by Art 2. For second class add full one-eighth part; and for superior brick one-fourth to one-third part, if the span exceeds about 15 or 20 ft. Original.

Art. 4. To proportion the abuts for an arch of stone or brick, whether circular or elliptic. (Original.)

The writer ventures to offer the following rule, in the belief that it will be found to combine the requirements of theory with those of economy and ease of application, to perhaps as great an extent as is attainable in an endeavor to reduce so complicated a subject, to **a simple and reliable working rule for practical bridge-builders.** This is all that he claims for it. Notwithstanding its simplicity, it is the result of much labor on his part. It applies equally to the smallest culvert, and to the largest bridge; whatever may be the proportions of span and rise; and to any height of abut whatever. It applies also to all the usual methods of filling above the arch; whether with solid masonry to the level *v f*, Fig 2, of the top of the arch; or entirely with earth; or partly with each, as represented in the fig; or with parallel spandrel-walls extending to the back of the abut, as in Fig 2½. Although the stability of an abut cannot remain precisely the same under all these conditions, yet the diff of thickness which would follow from a strict investigation of each particular case, is not sufficient to warrant us in embarrassing a rule intended for popular use, by a multitude of exceptions and modifications which would defeat the very object for which it was designed.

It gives a thickness of abut, which, without any backing of earth behind it, is safe in itself, and in all cases, against the pres, when the bridge is unloaded. Moreover, in very large arches, in which the greatest load likely to come upon them in practice is small in comparison with the wt of the arch itself, and the filling above it, our abuts would also be safe from the *loaded* bridge, without any dependence upon the earth behind them; but as the arches become less, and consequently the wt of the load becomes greater in proportion to that of the arch, and of the filling above it, we must depend more and more upon the resistance of the earth behind the abuts, in order to avoid the necessity of giving the latter an extravagant thickness. *It will therefore be understood throughout that, except when parallel spandrel walls are used, our rules suppose that after the bridge is finished, earth will be deposited behind the abuts, and to the height of the roadway, as usual.*

In small bridges and large culverts of first class railroads, subject to the jarring of heavy trains at high speeds, the comparative cheapness with which an excess of strength can thus be given to important structures, has led, in many cases, to the use of abutments from one-fourth to one-half thicker than by the following rule **If of rough rubble** add 6 ins to insure full thickness in every part

$$\left.\begin{array}{c}\textit{Thicks o n of abut at spring}\\ \textit{in ft, when the height o s}\\ \textit{does not exceed } 1\tfrac{1}{2} \textit{ times the}\\ \textit{base s p}\end{array}\right\} = \frac{\textit{Rad in ft}}{5} + \frac{\textit{rise in ft}}{10} + 2\,\textit{ft}.$$

Mark the points n and y thus ascertained. Next, from the center i, of the span or chord eo, lay off ih, equal to $\frac{1}{24}$ part of the span. Join ah; and through n, and parallel to ah, draw the indefinite line gnp of the abut. Do the same with the other abut. Make ym and ng each equal to half the entire height it of the arch; and from g draw a straight line gx, touching the back of the arch as high up as possible; or still better, as shown at tm, with a rad dt or dm, (to be found by trial,) describe an arc tm. Then gx or tm will be the top of the masonry filling above the arch;* and this should be completed before striking the centers; before which, also, the embkt should be finished, at least up to yn.

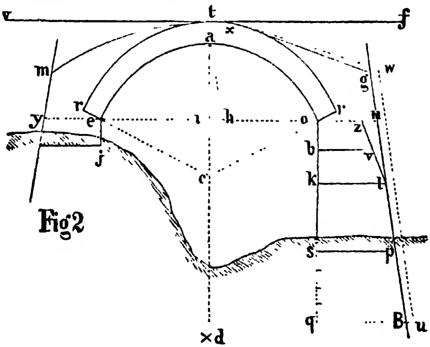

Fig 2

Now find by trial the point s, Fig 2, at which the thickness sp is equal to two-

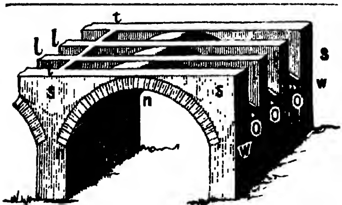

Fig $2\frac{1}{2}$

* EXCEPT WHEN THE RISE IS BUT ABOUT $\frac{1}{4}$ OF THE SPAN, OR LESS, in which case carry the masonry up solid to the level vtf, of the top of the arch. Or if the arch is a large one, exceeding say about 60 ft span, and especially if its rise is greater than about $\frac{1}{5}$ of its span, it is better to economize masonry by the use of parallel interior spandrel-walls, ll, Fig $2\frac{1}{2}$, carried up to vtf, Fig 2. Indeed, such interior walls may often be advantageously introduced in much smaller arches. When high, they are steadied by occasional cross-walls, as tt, Fig $2\frac{1}{2}$. Their feet should be spread by offsets, as shown at o o o, so as to bear upon the whole surf of the back of the arch; thus equalizing the pres upon it. On top of the walls flagstones may be laid, or small arches may be turned from wall to wall, for supporting the ballast, &c, of the roadway. The spaces below are left hollow. In Fig $2\frac{1}{2}$ the dark part ww is supposed to be a section across an abutment; but omitting the second cross-wall, similar to ss. In R R bridges, put a spandrel-wall, ll, under each rail.

thirds of the corresponding vert height *o s*, and draw *s p*. Then will the *thickness* *o n* or *e y* be that at the springing line of the given circular or elliptic arch of any rise and span; and the line *g p* will be the *back* of the abut; provided its height *o s* does not exceed 1½ times *s p*; or in other words, provided *s p* is not less than ⅔ of *o s*. In practice, *o s* will rarely exceed this limit; and only in arches of considerable rise. But if it should, as for instance at *o q*, then make the base *q u* equal to *s p*, added to one-fourth of the *additional* height *s q*; and draw the back *u w*, parallel to *g p*; and extending to the same height, &c, as in Fig 2. If, however, this addition of ¼ of *s q* should in any case give a base *q u*, less than *one-half* the total height *o q*, (which will very rarely happen in practice,) then make *q u* equal to half said total height; drawing the back parallel to *g p*, and extending it to the same height as before. The additional thicknesses thus found below *s p*, have reference rather to the pres of the earth behind the abut, than to the thrust of the arch. In a very high abut, the inner line *g p* would give a thickness too slight to sustain this earth safely.

When the height *o b*, Fig 2, of the abut is less than the thickness *o n* at spring, a small saving of masonry (not worth attending to, except in large flat arches) may be effected by reducing the thickness of the abut throughout, thus: Make *o k* equal to *o n*, and draw *k l*. Make *o z* equal to ¾ of *o n*, and draw *l z*. Then, for any height *o b* of abut less than *o n*, draw *b v*, terminating in *l z*. This *b v* will be sufficient base, if the foundations are firm. The back of the abut will be drawn upward from *v*, parallel to *g p*, and terminating at the same height as *g* or *w*.

Rem. 1. All the abuts thus found will (with the provisions in Art 6) be safe, without any dependence upon the wing-walls; no matter how high the embkt may extend above the top of the arch. If the bridge is narrow, and the inner faces of the wing-walls are consequently brought so near together as to afford material assistance to the abuts, the latter may be made thinner; but to what extent, must depend upon the judgment of the engineer.

We, however, caution the young practitioner to be careful how he adopts dimensions less than those given by our rule. There are certain practical considerations; such as carelessness of workmanship; newness of the mortar; danger of undue strains when removing the centers; liability of derangement during the process of depositing the earth behind the abuts, and over the arch; &c, which must not be overlooked; although it is impossible to reduce them to calculation.

Whenever it can be done, the centers should remain in place until the embkt is finished; and for some time afterward, to allow the mortar to set well. But for more on this see Rem 4. p. 633.

Rem. 2. A good deal of liberty is sometimes taken in reducing the quantity of masonry above the springing line of arches of considerable rise, and of moderate spans. When care is taken to leave the centers standing until the earth filling is completed above the arch, and behind its abuts, so that it may not be deranged by accident during that operation; and when good cement is used instead of common mortar, such experiments may be tried with comparative safety; especially with culvert arches, in which the depth of arch stones is great in proportion to the span. They must, however, be left to the judgment of the engineer in charge; as no specific rules can be laid down for them. They can hardly be regarded as legitimate practice, and we cannot recommend them. We have known nearly semicircular arches, of 30 to 40 ft span, to be thus built successfully, with scarcely a particle of masonry above the springs to back them. Such arches, however, are apt to fall, if at any future period the earth filling is removed, without taking the precaution to first build a center or some other support for them. Even when the embkt can be finished before the centers are removed, we cannot recommend (and that only in small spans) to do *less* than to make *n g*, Fig 2, equal to ⅙ of the total height *i t* of the arch; and from *g* so found, to draw a straight line touching the back of the arch as high up as possible.

Rem. 3. We have said nothing about **battering the faces of the abuts,** because in the crossing of streams, the batter either diminishes the water-way; or requires a greater span of arch. Such a batter, however, to the extent of from ½ to 1½ ins to a ft, is useful, like the offsets, for distributing the wt of the structure, and its embkt, over a greater area of foundation; especially when the last is not naturally very firm; or when the embkt extends to a considerable height above the arch. In our tables, Nos 3 and 5, of approximate quantities of masonry in semicircular bridges of from 2 to 50 ft span, the faces are supposed to be vert.

Art. 5. Abutment-piers. When a bridge consists of several arches, sustained by piers of only the usual thickness, if one arch should by accident of flood, or otherwise, be destroyed, the adjacent ones would overturn the piers; and arch after arch would then fall. To prevent this, it is usual in important bridges to make some of the piers sufficiently thick to resist the pres of the adjacent arches, in case of such an accident; and thus preserve at least a portion of the bridge from ruin. Such are called abutment-piers.

Our formula of $\frac{\text{Rad}}{5} + \frac{\text{Rise}}{10} + 2$ ft, for the thickness at spring; with the back battering as before, at the rate of $\frac{1}{24}$ of the span to the rise; face vert; will of itself (*without any modification for great heights*) give a perfectly safe abut pier, for any unloaded bridge; and to any height whatever; due regard being had, however, to the consideration alluded to in the next Art. Thus, for an abut-pier as high as *o q*, Fig 2; or of any greater height; it is only necessary first to find the thickness *o n* at spring as before; and then draw the battered back *g n p*; extending it down to the base at B; without adding ¼ of the additional height *s q*. This addition is made in the case of abuts, that they

may be secure from the pres of the *earth* behind them; as well as from the pres of the arch; a consideration which does not apply to abut-piers; in which only the pres of the arch is to be resisted.

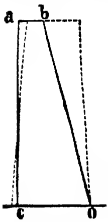

Fig 3

But although the abut-pier thus found by our formula, would be abundantly safe, yet its shape *a b c o*, Fig 3, is inadmissible. In practice it would be changed to one somewhat like that shown by the dotted lines; having an equal degree of batter on both faces. This of course requires more masonry, with but little increase of stability, but that cannot be avoided.

WHEN AN ABUT-PIER IS BUILT IN DEEP WATER, or in a shallow stream subject to high freshets, care must be taken that water cannot find its way *under* the pier, and thus produce an upward pres, which will either diminish, or entirely counteract its efficiency as an abut. See Remark 2, Art 4, of Hydrostatics.

Art. 6. Inclination of the courses of masonry below the springs of an arch. Although our foregoing rule gives a thickness of abut which cannot be *overturned*, or *upset*, by the pres of the arch, yet if the arch be of large span, and small rise, its great hor thrust may produce a *sliding* outward of the masonry near the level of the springs, if the stones are laid in *hor* courses; especially if the mortar has not set well.

This danger, it is true, could be avoided by confining the courses together by iron bolts and cramps; or by increasing considerably the thickness of the abuts; but the expense of doing either of these, leads to the cheaper expedient of inclining the masonry, as shown between *o* and *n*, Fig 4; the courses near *o* being steeper; and gradually becoming less steep near *n*. By this process the arch is virtually prolonged into the body of the abut, so far that when the inclination of the lower masonry ceases, as at *n*, the direction of the theoretical *line of thrust*, or *of pres* of the arch, (rudely represented by the dotted curved line *o n*) is nearly at right angles to the joints of the hor masonry below *n*; and consequently, said thrust is unable to produce sliding at that point. Between *o* and *n*, the line of pres is everywhere so nearly at right angles to the variously inclined joints, as to preclude the possibility of sliding in that interval also

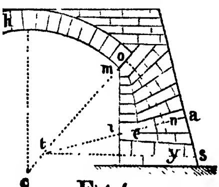

Fig. 4

The abut being thus safe throughout from both overturning and sliding, can fail only from defective foundations; or from the inferiority of the stone of which it is built; and which, if soft, may be crushed.

This inclination of the masonry is as necessary in an elliptic arch, Fig 4½, as in a circular one.

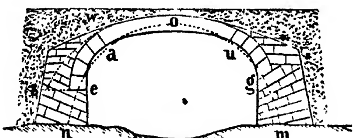

Fig. 4½

The elliptic form is plainly unfavorable for uniting the arch-stones with the inclined masonry near the springs, so as to receive the thrust properly; or about at right angles to its resultant. In ordinary cases this difficulty may be overcome by making the joints of only the outside or showing arch-stones to conform to the elliptic curve; as between *e* and *a*; while the joints of the inner or hidden ones, may have the directions shown between *g* and *u*, nearly at right angles to the line of thrust. It will rarely happen, however, that the young engineer will have to construct elliptic arches of sufficient magnitude to require either this, or any equivalent expedient. For spans less than 50 ft, with rises not less than about $\frac{1}{5}$ of the span, nothing of the kind is actually necessary, if the mortar is good, and has time to harden.†

In order to incline the masonry of any abut with sufficient accuracy, it would be necessary first to trace the curved line of pres of the given arch, so as to arrange the bed joints about at right angles to it at every point of its course; but we offer the following process as sufficing for all ordinary practical purposes, while its simplicity places it within the reach of the common mason. In actual bridges the direction of the actual thrust changes as the load is passing; therefore, in practice no given degree of inclination of the abut masonry can conform to it precisely during the entire passage. Consequently, any excess of refinement in this particular, becomes simply ridiculous, especially in small spans.

Rule for inclining the beds of the masonry in the abuts. Add together the rad *c m*, Fig 4; and the span of the arch. Div the sum by 5. To the quot add 3 ft. Make *o t*, on the rad, equal to the last sum. Then is *t* a central point, toward which to draw the directions of the beds, as in the fig. Draw *t s* hor, and from *t* as a center, describe the arc *o y*; *o* being the center of the depth of the springers. From *y* lay off on the arc the dist *y n*, equal to one-sixth part of *t y*; draw *t n a*. It will never be *necessary* to incline the masonry below this *t n a*. Neither *need* the inclination extend entirely to the face *m i* of the abut; but may stop at *e*, about half-way between *i* and *n*. From *e* upward, the inclination may extend forward to the line *e m*.

Cement should be freely used, not only in the arches themselves, and in the masonry above them, as a protection from rain-soakage; but in abuts, wing-walls, retaining-walls, and all other important masonry exposed to dampness. The entire backs of important brick arches should be covered with a layer of good cement, about an inch thick. The want of it can be seen throughout most of our public works. The common mortar will be found to be decayed, and falling down from the soffits of arches; and from the joints of masonry generally, within from 3 to 6 ft of the surface of the ground. The moisture rises by capillary attraction, to that dist above the surf of the nat soil; or descends to it from the artificial surf of embankments, &c; therefore, cement-mortar should be employed in those portions at least. The mortar in the faces of battered walls even when the batter is but 1 to 1½ inches per foot, is far more injured by rain and exposure, than in vert ones; and should therefore be of the best quality. See MORTAR, &c.

We have, however, seen a quite free percolation of surface water through brick arches of nearly 3 ft in depth, even when cement was freely used. In aqueduct bridges, we believe that cement has not been found to prevent leaks, whether the arches were of brick, or even of cut-stone. May not this be the effect of cracks produced by settlement of the arch; or by contraction and expansion under atmospheric influence? Cement at any rate prevents the joints from crumbling.

† The feet of both elliptic and semicircular arches are always made hor; but it is plain from Fig 4¾, that this practice is at variance with correct principles of stability in the case of the ellipse. It is the same in the semicircle. In ordinary bridges of the latter form, the vert pres, or weight resting on each skewback, is (roughly speaking) usually about from 3¼ to 4 times the hor pres on the same: and the total pres is about 4 times as great as the pres on the keystone. Therefore, theoretically, the skewback should usually be about 4 times as deep as the keystone; and its bed, instead of being hor, should be inclined at the rate of about 1 vert to 4 hor.

When the arch is flat, this inclination may become so steep, especially in the upper parts, that struts, or shores of some kind, must be used for preventing the masonry from sliding down, until the completion of the arch secures it from doing so. The hor courses between the face *m i*, and the line *o e*, will aid somewhat in this respect.

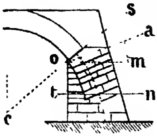

Fig 5

This method should be applied to *all very large arches* whose rise is one-third, or less, of the span. As before remarked, it is not actually necessary in arches not exceeding about 50 ft span, and not flatter than $\frac{1}{5}$ of the span. Indeed, if the earth filling can be deposited before the centers are removed, these limits may be considerably extended without danger. Still, since a certain degree of inclination is attended with very little trouble or expense, we would recommend for even such arches, a process somewhat like the following From *half* the span take the rise. Div the rem by 3. Make *o t*, Fig 5, equal to the quot Draw *t n*, and *o m*, hor. Div the angle *s o m* into two equal parts, by the line *o a*. Incline the masonry so as to be parallel to *o a*, as far down as *t n*. The inclined courses may extend out to the face *o t*, or not, at pleasure.

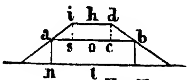

Fig 7

REM. 1. **To find the length** (*a b*, Fig 7) **from face to face of a culvert.** From the height *h t* of the embkt, take the *above ground* height *n a* of the culvert, the rem will be the height *h o* of the embkt *above* the culvert Then the reqd length *a b* is plainly equal to the top width *i d* of the embkt, added to the two dists *a s*, *c b*, which correspond to its steepness of side slopes. Thus, if the side slope is, as usual, 1½ to 1, then *a s* and *c b* will each be equal to 1½ times *o h*, or the two together will be 3 times *o h*. So that if the width *i d* is 14 ft, and *h o* 5 ft, the length *a b* will be

$$14 + (5 \times 3) = 14 + 15 = 29 \text{ ft}$$

Art. 7. The following tables, 3, 4, and 5, of quantities, will be found useful for expediting preliminary estimates, for which purpose chiefly they are intended; hence no pains have been taken to make them scrupulously correct, but rather a little in excess of the truth. The first column of Table 3 contains the total vert height *o e*, Fig 6, from the crown *o* of a semicircular arch, to the foundation or base *g m* of its abut The other columns give approximately the number of cub yds contained in each running foot, or foot in length of the culvert or bridge, measured from end to end (face to face) of the arch proper; and including only the arch and its abuts, as shown in Fig 1; or in the half section *o p m g y* in Fig 6; including footings to the abuts, but omitting the wing-walls (*w n*), and the spandrel-walls (*s*), Figs 6 and 2½. At the foot of each column is the approximate content in cub yds of the two spandrel-walls by themselves; one over each face of the arch.

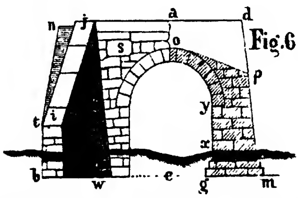

Fig. 6

These spandrel-walls are calculated on the supposition that their thickness at base, at their junction with the wing-walls, where their height is greatest, is equal to $\frac{4}{10}$ of their height at that point: except where that proportion gives a less thickness at top than 2½ ft; and that they extend 2 ft (*o a*) above the top *o* of the arch. At the top of the arch, they are all supposed to be 2½ ft thick at top; that being assumed to be about the least thickness admissible in a rubble wall in such a position. Both the back and the face are supposed to be vert. The contents of these spandrel-walls will vary somewhat, however, even in the same span, with the height of the abut and the arrangement of the wings. They, however, constitute so small a proportion of the entire contents given in Table 5, that this consideration may be neglected in preliminary estimates. They are so firmly bonded into the masonry of the wings at their highest points, and so strongly connected by mortar with the backing of the arch at their bases, that they require no greater thickness however high the emb may be.

The contents of the four wing-walls, of which *n j w b*, Fig 6, is one, will be found in a table (No. 4) immediately following that for the body of the culvert. We have also added a table (No. 5) for complete semicircular culverts of various lengths, including their spandrel and wing walls.

Rem. 1. Although the thickness of wing-walls increases in all parts with their height, they are not made to *show* thicker at *nj* than at *ti*, Fig 6; but (as seen in the fig) are offsetted at their back *n*, a little below their slanting upper surf *ij*, so as to give a uniform width for the steps or flagstones, as the case may be, with which they are covered. In the fig the covering is supposed to be of flagstones; but steps are preferable, being less liable to derangement. To prevent the flagstones from sliding down the inclined plane *j i*, the lower stone *i* should be deep and large, and laid with a hor bed. The flags are sometimes cramped together with iron, and bolted down to the wall. Steps require nothing of that kind, as seen at *s*, Fig 11.

Rem 2 **The tables show the inexpediency of too much contracting the width of water-way,** with a view to economy, by adopting a small span of arch, when a culvert of greater span can be made, *of the same total height.*

For the wings must be the same, whether the span be great or small, provided the total height is the same in both cases; and since the wings constitute a large proportion of the entire quantity of masonry, in culverts of ordinary length, the span itself, within moderate limits, has comparatively little effect upon it. Thus, the total masonry in a semicircular culvert of 3 ft span, 8 ft total height, and 60 ft long between the faces of the arch, is, by Table 5, 151½ cub yds, while that of a 5 ft span of the same height and length, is 152.4. A semicircular bridge of 25 ft span, 24 ft total height, and 40 ft between the faces of the arch, contains 1031 cub yds; while one of 35 ft span, of the same height and length, contains 1134 yds, so that in this case we may add nearly 50 per cent to the water-way, by increasing the masonry of the bridge but $\frac{1}{10}$th part.

Rem. 3. Partly for the same reason, and partly because **the culverts for a double-track road are not twice as long as those for a single-track one,** the quantity of culvert masonry for the former will not average more than about from ¼ to ⅛ part more than that for the latter; so that it frequently becomes expedient to *finish* the culverts at once to the full length required for a double track, although the embkts may at first be made wide enough for only a single one, with the intention of increasing them at a future time for a double one.

Thus, the average size of culverts for a single track may be roughly taken at 6 ft span, 30 ft long from face to face, and 10 ft total height; and such a one contains, by Table 5, 140 cub yds. For a double track, it would require to be about 12 feet longer; and we see by Table 3 that this will add 2.67 × 12 = 32 cub yds, making a total of 172 yds instead of 140; thus adding rather less than ¼ part. When the culverts are under very high embkts, and consequently much longer, the addition for a double track becomes comparatively quite trifling.

Table 3, of approximate numbers of cub yds of masonry per foot run, contained in the arches and abutments only, as shown in Fig 1 (omitting wings, and the spandrel-walls over the faces of the arches) of semicircular culverts and bridges, of from 2 to 50 ft span, and of different total heights, *ht*, Fig 1, or *oc*, Fig 6. It will be seen that in many cases, a bridge of larger span contains less masonry than one of smaller span, *when their total heights are the same.* There is a liberal allowance for footings or offsets at the bases of the abuts.

Art. 8. The following table of contents of wing-walls, or wings, will, like the preceding one, be useful in making preliminary estimates. The wings *so*, *no*, shown in plan at Fig 8, are supposed to form an angle *aoc*, of 120°, with the face, or end *oo* of the culvert. Their outer or small ends *nn*, are all assumed to be of the dimensions shown on a larger scale at E. Thickness at base at every part equal to $\frac{4}{10}$ of the height of the wall at said part; except when that proportion becomes too small to allow the width or thickness at top to be 2.5 ft; in which case it is enlarged at such parts sufficiently for that purpose. See Remark 2. This happens only

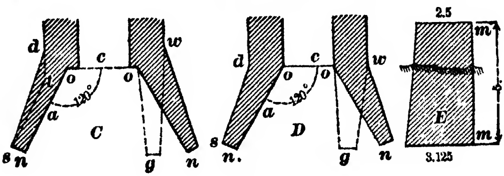

Fig. 8

when the height *m m*, Fig. E, of the wing, becomes less than 9 ft. Batter of face, $1\frac{1}{2}$ ins. to a ft.; or 1 in 8. Back vert.; but offsetted, if necessary, for a short dist. below the top, so as to give a uniform *showing* top thickness of $2\frac{1}{2}$ ft. The masonry is supposed to be good well-scabbled mortar rubble. The height given in the first column is the greatest one; or that at *oo* (or *wj*, Fig. 6), where the wing joins the face of the culvert. In the table no allowance is made for footings (offsets or steps) at the base of the wings; as these are frequently omitted in wings on good founda-

tions. In taking out quantities from the table, bear in mind that the height of the wings is usually a little greater than that of the culvert itself.

The plan shown at C is the common one, but that at D is greatly preferable for culverts; for the shoulders at *o o* in Fig. C, apart from their greater liability to catch branches of trees, etc., floating down stream, offer of themselves a much greater resistance to the flow of the water into the culvert than do the mere corners at *o o*, Fig. D.

Table 4, of approximate contents, in cub yds, of the four wing-walls of a culvert, or bridge. (Original.)

The heights are taken where greatest, as at *j w*, Fig 6

Height of wing	Length of one wing.	Cub. yds. in 4 wings	Height of wing	Length of one wing.	Cub. yds. in 4 wings.

28	39.8	672	70	113	10155

To reduce cub yds to perches of 25 cub ft, mult by 1.080.
To reduce perches to cub yds, mult by .926, or div by 1.08.

The contents for heights intermediate of those in the table may be found approximately by simple proportion.

REM. 1. It is not recommended to actually prolong all wings until their dimensions become as small as shown at E, in Fig 8. In large ones it will generally be more economical to increase their end height *m m*, a few feet. The contents, however, may be readily found by the table in that case also. Thus suppose the height of the wings at one end to be 30 ft, and at the other end 8 ft; we have only to subtract the tabular content for 8 ft high, from that for 30 ft high. Thus, 818 — 14.6 = 803.4 cub yds required content.

REM. 2. It might be supposed that inasmuch as the wings of arches often have to sustain the pressure from embankments reaching far above their tops, they should, like ordinary retaining-walls, be made much thicker in that case. But the fact that they derive great additional stability from being united at their high ends to the body of the bridge or culvert, renders such increase unnecessary when proportioned by our rule; no matter how far the earth may extend above them; as shown by abundant experience.

Relying upon this aid, we may indeed, when the earth does not extend above the top, reduce the base at *o* to one third of the ht, as shown at *o t*, and by dotted line *t s*. Experience shows that we may also do the same even when the earth reaches to a great height above the top, provided that the wings, instead of being splayed or flared out, as at *o n*, *o n*, merely form straight prolongations of the abutments of the arch, as shown by the dotted lines at *o g w*. In this case the pressure of the earth against the wings is less than when they are splayed. We have known the thickness at *o* to be reduced in such cases to less than one-third the height, when the wings were 15 ft high, and the height of the embankment *above their tops* 16 feet in one case, and 36 ft in another. In another instance, similar wings 25½ ft high, and with 29 ft of embankment above their top, had their bases at *o* rather less than $\frac{1}{5}$ of the height. In all these cases, the uniform thickness at top was 2.5 feet; backs vertical. We mention them because this particular subject does not seem to be reducible to any practical rule. The last wall appears to us to be too thin; especially if the earth is not deposited in layers, and after allowing the mortar full time to set. The labor, however, required in compacting the earth carefully in layers, may cost more than is thereby saved in the masonry. The young practitioner must bear this in mind when he wishes to economize masonry by such means; and also that the thin wall may bulge, or fail entirely, if the earth backing is deposited while the mortar is imperfectly set.

Table 5. Approximate contents in cubic yards, of com- plete semicircular culverts and bridges of from 2 to 50 feet span; including the 2 spandrel walls, and the 4 wings; all proportioned by the oregoing directions; and taken from the two preceding tables. The height in the econd column, is from the top of the *keystone* to the bottom of the foundation. The ings are calculated as being 2 ft higher than this, including the thickness of the oping. The wings are frequently carried only to the height of the top of the arch, hus saving a good deal of masonry. Table 4, of wings alone, will serve to make the roper deduction in this case.

The several lengths are from end to end, or from face to face, of the *arch proper* The contents for intermediate lengths may be found exactly; and those for inter- nediate heights, quite approximately, by simple proportion. In this table, as in No. 3, it will be observed that *when the heights are the same in both cases*, a larger pan frequently contains less masonry than a smaller one. A semicircular culvert r bridge contains less masonry than a flatter one, when the total height is the same n both cases; therefore, the first is the most economical as regards cost; but it does ot afford as much area of water-way; or width of headway.

Art. 9. Especial pains should be taken to **secure an unyielding foundation for culverts and drains under high embkts;** otherwise the superincumbent weight, especially under the middle of the embkt, may squeeze them into the soil below, if soft or marshy; and thus diminish the area of waterway, or at least cause an ugly settlement at the midlength of the culvert. Also, in soft ground, the embkt may press the side walls closer together, narrowing the channel This may be prevented by an inverted arch, or a bed of masonry, between the walls. A stratum from 3 to 6 ft thick, of gravel, sand, or stone broken to turnpike size, will generally give a sufficient foundation for culverts in treacherous marshy ground; or quicksand, with but a moderate height of embkt. It should extend a few feet beyond the masonry in every direction, and should be rammed; the sand or gravel being thoroughly wet, if possible, to assist the consolidation. Piling will sometimes be necessary. If the masonry is built upon timber platforms, or a smooth surface of rock, care must be taken to prevent it from sliding, from the pres of the earth behind it. This same pres may even overthrow the piles, if they are not properly secured against it.

Art 10. Drains. Drains of the dimensions in Fig 11, contain 1 perch, of 25 cub ft; or .926 of a cub yd, per ft run.

They are frequently built of dry scabbled rubble, and paved with spawls. When there is much wash through them, with a considerable slope, it is better to continue the foundation

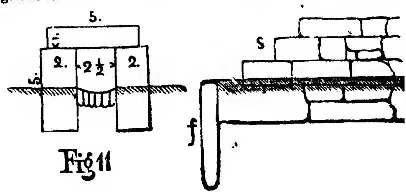

Fig 11

solid clear across. This is often done without those causes, inasmuch as the additional masonry is a mere trifle; and the excavation of a single broad foundation pit is less troublesome than that of two narrow ones. A deep flag-stone *f* at the entrance, and others at short dists of the length, may be introduced in both drains and culverts, to protect from undermining.

These drains extend under the entire width of the embkt, from toe to toe, and may terminate in steps, as in the side view at S. They are of course better when built with mortar, with an admixture of cement to prevent the water when full from leaking into and softening the embankment.

Sometimes two or three such drains may be placed parallel to each other instead of a culvert. When two are so placed, they contain only $1\frac{1}{2}$ times the masonry of one, still their use will generally involve no saving of masonry over a culvert. A man can crawl through Fig 11 to clean it.

Art. 11. The drainage of the roadways *of stone bridges of several arches, is generally effected by means of open gutters, which descend slightly from the crowns of the arches, each way, until they reach to near the ends of the respective spans.*

There they discharge into vertical iron pipes built into the masonry. The upper ends of the pipes should be covered by gratings. When inconvenience would result from the water falling upon persons passing under the arches, these pipes may be carried down the entire height of the piers; but when such is not the case, they may extend only to the soffit, or under face of the arch; allowing the water to fall freely through the air from that height.

Table 6, of approximate contents, in cub yds, of a solid pier of masonry, 6 ft by 22 ft on top; and battering 1 inch to a ft on each of its 4 faces. The contents of masonry of such forms must be calculated by the prismoidal formula, and not by taking the length and breadth of the pier at half its height as an average length and breadth, as is sometimes done. This incorrect method would give only 6492 cub yds as the content of the pier 200 ft high; instead 7178 yds, its true content. High piers may for economy be built hollow, with or without interior cross walls for strengthening them, as the case may require; and the batter is generally reduced to ½ inch or less to a foot. Hollow piers require good well bedded masonry.

Art. 12. Brick Arches. Since even good brick fit for large arches has far less crushing strength than good granite or limestone, and is inferior even to good sandstone, while its weight does not differ very materially from stone, it is plain that it cannot be used in arches of as great span as stone can. Some of those already built, and which have stood for many years, have a theoretical co-efficient of safety of but about 3; whereas the authorities direct us not to trust even stone with more than one-twentieth of its crushing load. This last, however, appears to the writer to be one of those hasty assumptions which, when once admitted into professional books, are difficult to be got rid of. It is his opinion that with good cement, and proper care in striking the centers, one-tenth of the ultimate strength is sufficiently secure against even the abnormal strains caused by the settling at crown, and rising at the haunches when the centers are struck. It is useless to attempt to fix limits of safety for bad materials poorly put together.

Rem. 1. The common practice of building brick arches in a series of **concentric rings**, as at *a c e e*, Fig 12, with no other bond between them than that afforded by the mortar, is censured by authorities, on the ground that the line of pressure in passing from the extrados to the intrados tends to separate the rings, and thus weaken the arch by, as it were, splitting it longitudinally. The reason for using these rings, instead of making the radial joints continuous throughout the depth *m n* of the arch, as at *b*, is to avoid the thick mortar-joints at the back of the arch, and shown in the Fig. If the center of an arch built as at *b* be struck too soon, the soft mortar in these thick joints will be so much compressed as to cause great settlement at the crown, throwing the arch out of shape, and creating such inequality of pressure as might even lead to its fall, especially if flat. As a compromise between rings and continuous joints, they are sometimes employed together, so as to get rid of **some** of the long radial joints; and at the same time to break **at intervals** the continuity of the rings. Thus in Fig 12, which is supposed to be brick-and-a-half deep, beginning at the abutment *a*, we may lay half-brick rings as far as say to *e o e;* then **cutting away** the brick *o* to the line *e e*, we may lay from *e e* to *m n* a block of bricks with continuous radial joints, the same as at *b;* and then start again with three rings; and so on alternately. A still better, but more expensive, mode would be to fill *e e*, *m n* with a regular cut-stone voussoir.

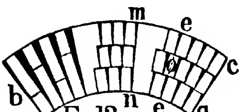

Fig.12.

The proper intervals for changing from rings to blocks will depend upon the number of the rings and the depth *c a* of the arch; reference being also had to reducing the amount of brick cutting as much as possible.

These points can be best decided on from a drawing of a portion of the arch on a scale of 3 or 4 ins to a foot. Generally the rings are made only half-brick, or about 4 to 4.5 ins thick, as at *a c;* and in Brunel's Maidenhead viaduct of two elliptic brick arches of 128 ft span, and 24 25 ft rise; the boldest brick arches yet attempted; but which have been estimated to have a co-efficient of safety of but three against crushing at the crown

So many others of from 70 to 100 ft span have been successfully built entirely in rings of either half or whole brick thick, as to justify us in attaching but little weight to the above theoretical objection, provided first class cement be used, and time allowed it to become nearly or quite as hard as the bricks themselves, before striking the centers. Under such circumstances we should not object to a series of rings even 1.5 bricks thick, laid alternately header and stretcher, as at *b*.

If the bricks were voussoir-shaped, that is, a little thicker at one end than the other, then rings a whole-brick thick could be used without any increase in thickness of mortar-joint at the back of each ring. Still with more than one ring, the radial joints would not be continuous, as at *b*, but broken as at *ac*. Such bricks however would be more expensive to make; and moreover, in order fully to answer the intended purpose, they would have to be made of many patterns, so as to conform to the many radii used in arches, and even to the radii of the different rings, when the depth of the arch required several of them.

Rem. 2. Wet the bricks before laying.

Rem. 3. When the ends or faces of a brick arch are to be finished with **cut-stone voussoirs,** these had better not be inserted until some time after the completion of the brickwork, the hardening of the mortar, and a partial easing of the centers; lest they be cracked or spawled by the unequal settlements of themselves and the bricks.

Rem. Brick arches, from their great number of joints are apt to settle much more than cut stone ones when the centers are removed, and thereby to derange the shape of the arch, and at times, without due care, even to endanger its safety, especially if it be large and flat. When the span exceeds about 30 to 35 ft, and particularly if flat, use only brick of superior quality in good **cement** mortar. With even best materials and work we advise the young engineer not to attempt brick arches for railroad bridges of greater spans than about the following. Considerably larger ones than some of them have been built, and have stood; but their coefs of safety are not in all cases satisfactory. In this table the rise is in parts of the span.

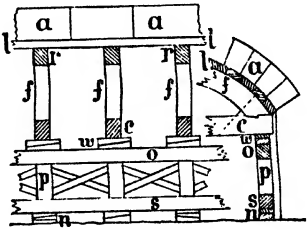
.36	93	1/4	75	.183	55	1/7	40		

On the **Filbert Street Extension of the Penna R R, in Phila,** are four brick arches of 50 ft 1 inch span, and with the very low rise of 7 ft. They are 2 ft 6 ins thick, except on their showing faces, where they are but 2 ft. The joints are in common mortar, and about 1/4 inch thick. These four arches, about 200 yards apart, with a large number of others of 26 ft span, form a viaduct. The piers between the short spans are 4 ft 3 ins thick. Those at the ends of the 50-ft spans, 18 ft 6 ins. The springing lines of all the arches are about 6 to 8 ft above the ground. One of the 50-ft arches settled 3 ins upon prer at rely striking the centers; but no further settlement has been observed, although the viaduct has, since built (1880) had a very heavy freight and passenger traffic, at from 10 to 20 miles per hour. Roadbed, about 100 ft wide, giving room for 9 or 10 tracks.

CENTERS FOR ARCHES.

Art. 1. A center is a temporary wooden structure (built lying flat, on a full size drawing, on a fixed platform, under cover or not) for supporting an arch while it is being built. It consists of a number of trusses or **frames**, *f*, *f*, Fig. 1, placed from 1 to 6 ft apart from cen to cen, and covered with a flooring *l*, *l*, of rough boards or planks, usually laid close, and called the **sheeting** or **lagging**, immediately upon which the archstones are laid. In Fig 3, the lagging is not laid close. There is no great economy in placing the frames very far apart, on account of the greater required amount of lagging, the thickness of which increases rapidly. For the thickness of lagging see Rem 9

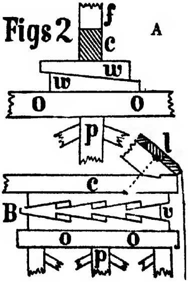


Figs 1.

The centers rest by the ends of their chords, *c*, upon wooden **striking wedges** *w*, Fig 1, supported by **standards** composed of posts *p*, whose tops are connected by **cap-pieces** *o*; and whose feet rest on **stringers** *s*; the whole being braced diagonally as shown.

If the ground is very firm, and the arch light, the standards may rest on it, with the interposition of **adjusting-blocks**, *n*, below the stringer, to accommodate irregularities of the surface of the ground, as in the Fig. These blocks shoul be somewhat double-wedge-shaped, so that by driving them the standard ma be raised at any point in case it should settle a little into the ground. But fo heavy arches the standards must rest on a much firmer foundation, such as shor blocks of brickwork sunk a few feet into the ground, or some other devic adapted to the case. Frequently projecting offsets or footings, or at times re cesses, are provided in the masonry of the abutments and piers for this expres purpose; and with a view to this it is well to design the center at the same tim as the arch.

Figs 2



Up to spans of 50 or 60 ft a single row of posts (one under each end of each frame) will suffice; but for much larger ones two or three rows, 2 or more feet apart may become expedient, as in the lower Fig 2.

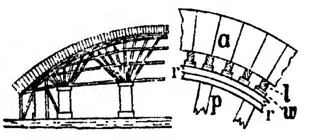
The striking or lowering-wedges before alluded to are for striking or lowering the center after the completion of the arch. They consist of pairs of wedge-shaped blocks, *w w*, at A, Figs 2, of hard wood, from 1 to 2 ft long, about half as wide, and a quarter or more as thick, (sufficient to lower the center from say 2 to 6 or more inches, according to span and other circumstances,) resting on the cap *o*, of the standard, while the chord *c* of the frame rests on *them*. When the end of a frame is supported by two or more posts *p*, as at B, Fig 2, instead of upon one, the striking-wedges are sometimes made as there shown; and where B *v* is one long wedge at right angles to the abutment, and acting as four wedges which may all be lowered together by blows against the end B.

each so long as to reach **transversely** across the entire arch. Then all the frames can be lowered at one operation, as described near end of Art 9.

If we had to consider only the friction of dry wood against dry wood, the taper of these wedges might be as steep as 1 vert to 3 hor, without any danger of their sliding upon each other of their own accord; and they would then require very moderate blows to start them, or even to entirely separate them, when the center had finally to be lowered. But it is of the utmost importance, especially in large arches, that the **centers should be lowered very slowly,** otherwise the momentum acquired by so heavy a body as the arch in descending suddenly even but 2 or 3 ins, might possibly affect its shape, or even its safety.

Therefore the wedges should not have a taper steeper than about 1 in 6 or 8 for arches of less than about 50 ft span; or than 1 in 8 or 10 for larger spans. Vertical lines at equal dists apart should be drawn on the long sides of the wedges as a guide for lowering them all to the same extent at a time; and this should not exceed in all about half an inch a day in intervals of about an eighth of an inch, for 50 ft spans; or about .1 to .25 of an inch per day in all, for spans over 100 ft. Slowness is especially to be recommended in **brick arches,** not only because their greater number of joints exposes them to greater derangement of shape, but because even good brick has much less than the average crushing strength of good granite, limestone, or sandstone, and therefore is far more liable than they to crack, or even to crush (as the writer has seen) when the strains are thrown almost entirely upon their edges, as described in Art 3.

At Gloucester Bridge, England, of first class cut stone, span 150 ft, rise 35 ft, the centers were entirely struck within the very short space of 3 hours, and the crown of the arch descended 10 ins! **At Grosvenor Bridge,** England, of first class cut stone, span 200 ft, rise 42 ft, such care was taken in easing the centers that the crown of the arch settled but 2.5 ins. This case however was marked by two or three peculiarities, all of which contributed to this favorable result. Namely, the center instead of being a series of frames supported as usual by their ends, and of course involving an appreciable, although small, degree of sagging or settlement, consisted essentially of vertical and inclined posts or struts, see Fig 3, footing on four temporary piers of masonry, 7 or 8 feet thick, built in the river, parallel to the abutments, and as long as they. These piers supported six frames (or rather six series) about 7 ft apart cen to cen, of such struts, footing on cast iron shoes. Fig 3 shows half of one series. Each frame or series consisted of four fan-like sets of posts, all in the same vertical plane. The long horizontal pieces seen extending from side to side of the arch were bolted to the struts to increase their stiffness, and other pieces for the same purpose united the six series transversely. Here each strut sustains its own share of the weight of the archstones, and transfers it directly to the unyielding foundation of the pier; whereas in the usual trussed centers, the entire load rests upon the frames, and is finally transferred to the comparatively unstable support of the posts at their ends.



Figs 3.

The tops p of the posts of a series varied about from 5 to 8 ft apart cen to cen; and were connected by a continuous curved rib, r r, of two thicknesses of 4 inch plank, bent to conform approximately to the curve of the arch. On this rib were placed pairs of striking-wedges w like Fig 2, about 16 ins long, 10 to 12 ins wide, and tapering 1.5 ins, so near together (varying about from 2.5 to 3.5 ft cen to cen) that there was a pair under each joint of the archstones, a a. On these wedges, and extending over all six of the frames, were the lagging pieces l, 4.5 ins thick.

This peculiar arrangement of the striking-wedges and lagging has, in large spans, great advantages over the usual one of placing them only at the ends of the frames. In the last the entire center and the entire arch are lowered together, without giving an opportunity to rectify any slight derangements of shape or inequality of bearing that may have occurred in the arch during its construction. This center, designed by Mr. Trubshaw, admits of lowering either the whole equally, or any one part a little more or less than the others. He had much experience in large arches, and stated that during the striking he found that he had an arch under better control, or could humor it better, by keeping the haunches a little down and the crown a little up, until near the end of

Rem. 1. Instead of piers of masonry for supporting the feet of the posts, wooden cribs or piles may often be used if the arch is over water.

The principle of supporting even trussed frames by struts at points of the chord as far from the abutments as circumstances will admit of (in addition to those at the very ends) should always be applied when possible, in order to reduce their sagging to a minimum. **Steps or offsets in the masonry** of the abutments and piers may be provided for receiving the feet of such struts, when they are inclined.

Rem. 2. Screws may be used instead of wedges for lowering centers. At the Pont d'Alma, Paris, ellipse of 141.4 ft span, and 28.2 ft rise, the frames were supported by wooden pistons or plungers, the feet of which rested on **sand confined in plate-iron cylinders** 1 ft in diam and height, and having near the bottom of each a plug which could be withdrawn and replaced at pleasure, thus regulating the outflow of the sand and the descent of the center. This device succeeded perfectly, and is well worthy of adoption under arches exceeding about 60 ft span. When much larger than this the driving of the wedges on striking requires heavy blows, and becomes a somewhat awkward operation, requiring at times a battering-ram, even when the wedges are lubricated. In railroad cuttings crossed by bridges, **the earth under the arch** has been made to serve as a center, by dressing its surface to the proper curve, and then embedding in it curved timbers a few feet apart, and extending from abut to abut, for supporting the close plank lagging.

Rem. 3. All centers must yield or settle more or less under the wt of the arch, especially when supported only near their ends; and since the arch itself also settles somewhat not only when the centers are struck, but for some time after, it is advisable to make them at first a little higher than the finished arch is intended to be. This extra height, when the supports are at the ends, may be from 2 to 4 ins per 100 ft of span for cut stone arches (according to time of striking, character of masonry, workmanship, etc.), and about twice as much in brick ones.

Rem. 4. The proper time for striking centers is a disputed point among engineers, some contending that it should be done as soon as the arch is finished and sufficiently backed up, and others that the mortar should first be given time to harden. It is the writer's opinion that inasmuch as in cut-stone arches the mortar joints should be very thin; and since, in such, the mortar is at best of very little service, it is of no importance when they are struck; provided the masonry backing, and the embkt up to $y\ n$ Fig 2, p 618, have been completed; but that in brick or rubble, the numerous joints of both of which require much mortar, (which for hardness should consist largely of cement,) 3 or 4 months, or longer, if possible, should be allowed it to harden sufficiently to prevent undue compression and consequent settlement when the centers are struck. The continuance of the centers need not interfere with traffic over the bridge.

Art. 2. The pressure of archstones against a center is very trifling until after the arch is built up so far on each side that the joints form angles of 25° or 30° with the horizontal. Theoretical discussions on this pressure make no allowance for accidental jarrings in laying the archstones, or by the accumulation of material ready for use, laborers working on it, &c. Without going into any detail, we merely advise on the score of safety not to assume it at less than about the following proportions or ratios to the weight of the entire arch, namely, in a semicircular arch .47, rise .35 span, .61; rise .25 span, .79; rise .2 span, .86; rise .167 span, or less, 1, or equal to the wt of the arch. This gives the pressure of a semicircular arch upon its centers rather less than half its wt. **The wt of the centers themselves** when supported only near the ends must be considered as part of the load borne by them.

Art. 3. We have seen that as an arch $a\ a\ a$ is being gradually built upward on both sides, after passing the points e, e, Fig 4, where its joints form angles $a\ s\ e$, of about 30° with the horizontal $a\ a$, the arch begins to press more and more upon the centers; thereby tending to flatten them at the haunches, as shown at h in the dotted line; and consequently to raise them at the crown, as shown at c. But as the building goes on still higher, the added stones press much more heavily upon the centers than those below had done, and thereby tend to a final derangement of the centers just the reverse of that caused by the lower ones; namely to depress them at the crown a, as at o; and consequently to raise the haunches as at n; and this the more because the upper stones actually tend to lift or ease the lower ones from the lagging. In some cases where this tendency has been increased by **forcing** the keystones into place by too hard driving, the lagging under the haunches could be drawn out without any trouble before the centers were eased at all. On striking the centers this tendency to sink at crown and

rise at haunches is very apt to exhibit itself more or less dangerously in the arch-stones themselves, as in Fig 5, causing those near the crown to press very hard together at the extrados, and to separate from each other at the intrados; while near the haunches the reverse takes place. Hence the angles of the stones are frequently split and spawled off near *c* and *h* by this unequal pressure. These

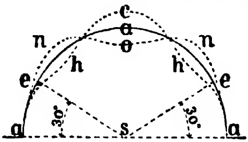


Fig. 4.

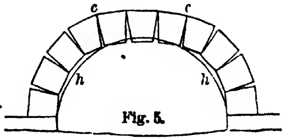

Fig. 5.

derangements are of course much more likely to be serious in high arches than in flat ones, especially if their spandrels are not sufficiently built up before lowering the centers

In the Grosvenor bridge, before alluded to, of 200 ft span, this dangerous excess of pressure near *c* and *h* was prevented by covering the skewback joint of the springing course at each abutment with a wedge of lead 1.5 ins thick at the intrados of the arch, and running out to nothing at the extrados. Beside this a strip 9 ins wide of sheet lead was laid along the intrados edge of every joint until reaching that point at which it was judged that the line of pressure would pass from the intrados to the extrados; after which similar strips were laid along the extrados edges of the joints, up to the crown. Hence when the centers were struck, this excess of pressure merely compressed the lead, and was thus enabled to distribute itself more evenly over the entire depth of the joints. See Trans Ins Civ Eng London, vol i. See also top of p 1213

At the bridge at Neuilly, France (of 5 elliptic arches of 120 ft span, and 30 ft rise), the centers were so radically defective in design that the arches sank 13.25 ins at crown during the time of building; and 10.5 ins more during and immediately after the striking; or say 2 ft in all Their construction made the striking very tedious and hazardous; greatly endangering the lives of the workmen and the existence of the arches. Some of the joints at the extrados at the haunches opened an inch each; and those at the intrados of the crown .25 of an inch By the exercise of great care and humoring in lowering the centers, these openings were much reduced.

Rem. 1. Chamfering the edges of the archstones diminishes the danger of their spawling off from unequal pressure, as does also the **scraping out of the mortar of the joints** for an inch or two in depth before striking the centers.

Rem. 2. It is evident that in order to prevent, or at least to diminish the alternate derangements of the center, those of its web members which at first acted as **struts** near the haunches, Fig. 4, to prevent them from sinking as at *h* must afterwards act as **ties** to prevent them from rising as at *n*; while those which at first acted as ties near the crown *a*, to prevent it from rising as at *c*, must afterwards act as struts to prevent it from sinking as at *o*. In other words, the principle of **counterbracing** must be attended to as well in a frame or truss for a center, as in one for a bridge.

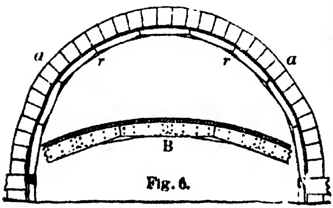

Fig. 6.

Art. 4. From the foregoing it is plain that **a simple unbraced wooden**

arch, or curved rib is, on account of its great flexibility, about as unfit a form as could be chosen for a center, except for very small spans, where a great proportional depth of rib can be readily secured. Still the writer has seen it used for a cut-stone semicircular arch of 35 ft span, with archstones 2 ft deep. Fig 6 shows one rib *r r*, and the arch, *a a*, drawn to a scale. Each rib consisted of two thicknesses of 2 inch plank in lengths of about 6.5 ft, treenailed together so as to break joint, as at B. Each piece of plank was 12 ins deep at middle, and 8 ins at each end; the top edge being cut to suit the curve of the arch. The treenails were 1.25 ins in diam; and 12 of them showed to each length. These ribs were placed 17 ins apart from cen to cen, and steadied together by a bridging piece of inch board, 13 ins long, at each joint of the planks, or about 3.25 ft apart. Headway for traffic being necessary under the arch, there were no chords to unite the opposite feet of the ribs. The ribs were covered with close board lagging, which also assisted in steadying them together transversely. As the arch approached about two-thirds of its height on each side, the ribs began to sink at the haunches, as at *h*, Fig 4; and to rise at the crown, as at *c*. This was rectified by loading the crown with stone to be used in completing the arch; which was then finished without further trouble.

A still more striking example of the use of a simple unbraced wooden rib, was in the old National Turnpike bridge over Wills Creek, at Cumberland, Md. This bridge, of which one arch with its center is shown in Fig 7 drawn to a scale, consisted of two elliptic cut stone arches 26.5 ft wide across roadway, and of 60 ft span, and 15 ft rise. The archstones were 3 ft deep at crown, and 4 ft deep at skewbacks. **Each frame of the center** was a simple rib 6 ins thick, composed of three thicknesses of 2 inch oak plank in different lengths (about 7 to 15 ft) to suit the curve and at the same time to preserve a width of about 16 ins at the middle of each length, and 12 ins at each of its ends. The thicknesses were well treenailed together, breaking joint and showing from 10 to 16 treenails to a length.

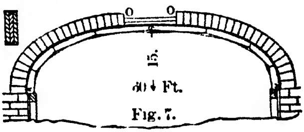

Fig. 7.

Here, as in Fig 6, there were no chords, owing to the violence of the floods in the creek. These ribs were placed 18 ins from cen to cen, and steadied against one another by a board bridging-piece 1 ft long, at every 5 ft. These were of course assisted by the lagging.

When the archstones had approached to within about 12 ft of each other near the middle of the span, the sinking at the crown, and the rising at the haunches had become so alarming that pieces of 12 × 12 oak, 00, were hastily inserted at intervals, and well wedged against the archstones at their ends. The arch was then finished in sections between these timbers, which were removed one by one as this was done.

Rem. 1. Such instances of partial failure are very instructive. It is indeed by such, rather than by theoretical deductions, that the proper dimensions are arrived at in a vast number of cases pertaining to engineering, machinery, &c.* Thus we might with entire confidence of no serious mishap, apply ribs of the foregoing dimensions to spans only half as great.

Rem. 2. Assuming the rib-planks to be 12 ins wide, it would, as a matter of detail, be better to make them about 10 ins wide at the ends instead of the 8 ins in Fig 6 making top curve 2 ins. To secure this, their lengths, depending on the **radius** of the rib, must not exceed those in **the following table:**

Rad of Arch.	Greatest Length.	Rad of Arch.	Greatest Length.
Feet.	Feet and Ins.	Feet.	Feet and Ins.
5	2 " 5	30	6 " 4
10	3 " 4	35	7 " 0
15	4 " 2	40	7 " 6
20	5 " 0	45	7 " 10
25	5 " 9	50	8 " 2

* The young engineer should make and preserve full notes in detail of all such as may fall within his notice.

If cut $1\frac{1}{2}$ times as long as this table, they will be very approximately 8 ins wide at ends; or each will on top curve 4 ins.

Art. 5. In cases where all possible headway is essential during the building of the arch, as in the two foregoing ones, the writer would suggest the expedient rudely illustrated by Fig 8; namely to **place the centers above the arch,** instead of **below** it; and after the arch is completed in sections, *a a*, instead of **lowering** the centers, **to take them apart.**

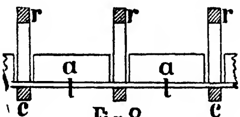

Fig 8.

Fig 8 is a transverse section through part of the center, and of the arch *a a*. Here *r c, r c, r c*, are frames of the center say 5 or 6 ft apart; and of any depth and construction whatever that may be necessary to insure absolute safety; and *l l* is the lagging Having built the arch from abutment to abutment in a series of sections *a, a, a*, necessarily separated say a foot or more by the deep frames, we may take the centers apart, and then fill in the narrow intermediate sections upon a lagging suspended by iron rods from the already completed sections Good concrete might be used for these narrow sections. In some cases it might be well to use **deep plate-iron ribs** of I section, resting the lagging on the lower flange Part of the web might be left remaining embedded in the masonry, and the upper part and both flanges removed after the arch is finished.

Art. 6. Centers with hor chords *c c* Fig 9 are objectionable (notwithstanding their strength) in large spans of great rise, as on right side of the Fig, on account of the excessive length required for the web members; and hence it will in such cases usually be found expedient to adopt something analogous to what is shown on the left hand of the Fig Here a truss *f*, shorter and shallower than that on the right hand, is substituted for the latter. At its ends provision must be made for supporting not only itself, but the archstones below it. As the pressure of these lower archstones is comparatively small, this may usually be effected by resting the end of the frame

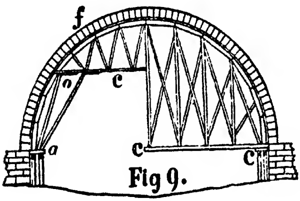

Fig 9.

f upon another and shallower frame *o a*. This may in large spans be aided by either inclined or vertical struts, either single or braced together; or as the trestles on p 1037 Sometimes one shallow truss like *f* is sustained upon another truss throughout its entire length. The striking-wedges for these various supports may be placed at either their tops or their feet, as may be most convenient.

Art. 7. For flat arches of 10 feet clear span, a mere board *o o* Fig 10, 12 ins deep, by 1.5 ins thick, with another piece *c* of the same thickness on top of it, trimmed to the curve, and confined to *o o* by nailing on two cleats of narrow board, will answer every purpose, with intervals of 18 ins from cen to cen. If the upper piece also is as much as 12 ins deep at its center, the clear span may be extended to 15 ft.

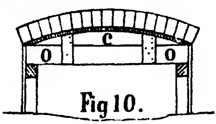

Fig 10.

For spans of 10 to 15 ft, and of any rise, two thicknesses of plank from 1 to 2 ins thick according to span; 8 to 12 ins wide at middle of each piece, in lengths as per table, Rem 2, Art 4, well **nailed** or **spiked** together, according to span, breaking joint as in Fig 6, will answer for distances of 2 to 3 ft apart cen to cen. For greater dists apart increase the thickness of the planks proportionally.

If the centers have to be moved from place to place, to serve for other arches, then, to preserve them from injury in handling, their feet should be united by nailing on one or both sides of each frame a chord piece of about 1

inch board, and also a vertical piece or pieces of the same size from the center of the chord to the top of the frame.

Even when they are not to be moved, the chord pieces are useful even in so small spans, inasmuch as they render the striking easier, by not allowing the feet of the ribs to give trouble by spreading outward and pressing against the abutments

For spans of 15 to 30 ft, and for any rise not less than one sixth of the span, the following dimensions, varying with the span, may be used for distances apart of 3 ft from cen to cen See Fig 11. **For the bow** *b*, two thicknesses of 1 to 2 inch plank from 9 to 12 ins wide at the middle, and from 7 to 10 ins at each end, well spiked together breaking joint as at B, Fig 6. **For the chord** *c*, two thicknesses of plank of same size as the bow at its middle; placed on outsides of bow, and well spiked to its ends **A vertical** *v*, in one piece as wide as a bow plank, and twice as thick Its top is placed under the bow, and is confined to it by two pieces, *o, o*, of bow plank twice as long as the bow plank is deep, and spiked to both *v* and the bow. The foot of *v* passes between the two thicknesses of the chord *c*, and is spiked to them. **Two oblique tie-struts,** *s*, each of two pieces of bow plank, outside of the bow and vertical *v*; footing against each other; and spiked to bow and *v* These with *v* divide the bow into 4 parts.

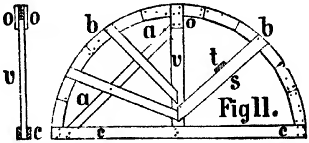

Fig 11.

Rem. 1. The above dimensions are suitable to a rise of one sixth If the rise is one fourth, the **thickness only** of the planks may be reduced one third part; and for a rise of one third or more, we may reduce to one half.

Rem. 2. If in the larger of these spans the struts *s* should show any inclination to bend sideways, nail on some pieces *t* from frame to frame. Also in the larger ones with rises exceeding one third, insert four double struts *s*, instead of two; thus dividing the bow into 6 parts, as at left side of Fig. 11. For spans of 25 to 35 ft, add also two struts like *a a*, of same size as *v*.

Art. 8. For spans greater than about 30 ft, the writer believes that as a general rule (liable to modifications according to the judgment of the engineer in charge) the following ideas will lead to safe practice. Namely, to adopt a bowstring truss with a simple Warren or triangular web, as at *f* on the left side of Fig 9. The bow to rest on the chord, and each to be of a single thickness. The web members (especially in large spans) to be also of single thickness, and placed below the bow, resting on the chords, and well strapped to both, so as to act as either ties or struts. In smaller spans the web members may each be in two thicknesses, one bolted or treenailed to each side of the bow and chord. Other modes will suggest themselves; but we have not space for such details.

Or a web of the Howe, or of the Pratt system, as on the right side of Fig 9 may be used. But in reference to both of these it may be remarked that **the use of long iron rods in centers** of large spans is highly objectionable, owing to the different rates of expansion between iron and wood. Therefore if these systems are used, all the members should be of wood. **The lattice** may be used

Even when the rise of the **arch** exceeds .25 of the span, it is better not to let that of the **centers exceed** that limit; but adopt the expedient shown at the left side of Fig 9, with a rise of about one sixth of the span.

Rem. 1. To fix on the number of web triangles in a Warren truss or frame for a center, find the square root of the span, and to it add one tenth of the span. Divide their sum by 2, and call the quotient *n*. Divide the span by *n*. If this quotient is a whole number use it; or if the quotient is partly decimal, use the whole number nearest to it, as a distance in feet to be stepped off along the chord; thus dividing the chord into a number of equal parts. All the points thus found on the chord, are the places for the **feet** of the triangles Next, from half way between each two of these points, draw vertical lines to the bow. The points thus found along the bow, are the places of the **tops** of the triangles. This rule will be used in connection with the following Table of Areas of Bows, as the two are dependent on each other.

In large arches **the timber of the bow should not be wasted** by trimming its upper edges to the curve of the arch, but should be left straight; and separate pieces so trimmed, like *c* in Fig. 10. should be spiked on top of them.

The transverse area of the bow, in square inches, may be taken from the following table; and may in practice be assumed to be uniform throughout its entire length; which in fact it is quite approximately. See Rem 2.

TABLE FOR BOWSTRING CENTERS.

Table of areas in square inches at the crown of each Bow, of **properly trussed** Bowstring frames for centers of stone or brick arches. The frames to be placed 5 feet apart from cen to cen. With these areas, the combined weights of arch, center (of oak), and lagging, will in no case in the table strain the Bow at crown of the greatest spans quite 1000 lbs per square inch; diminishing gradually to 600 or 700 lbs in the smallest spans, which are more liable to casualties.

Although centers of moderate span are usually made of white or yellow pine, spruce, or hemlock, all of which are considerably lighter than oak, we have for safety assumed them to be of oak, in preparing our table.

For spans of from 10 to 20 feet use the same sizes as for 20 feet.

Rem. 2. The square root of any of these areas gives in inches the **side of a square bow** of that area. The distances apart of the triangles which form the web of the frame, having first been found by Rem 1 (for said Rem and this table are dependent on each other), the above areas for bows 5 ft apart from cen to cen, suffice not only to resist the pressure along the bow, but also, as **square beams**, to sustain with a safety in no case less than about 5, the load of archstones resting upon them between the adjacent tops of two triangles; and with very trifling deflections. It is therefore unnecessary to deepen the ribs for that purpose; although it may be done (preserving the same area) in case considerations of detail should render it desirable.

As before suggested, it will generally be best, in spans exceeding 30 or 40 ft, to give the bow a rise not exceeding about one fifth or one sixth of the span; and to support the frames as at *f*, Fig 9.

The size of the chord may be the same as that of the bow; and like it uniform from end to end; care however being taken that it be not materially weakened by footing the bow upon its ends; or (when too long for single timbers) by the splicing necessary to prevent its being stretched or pulled apart by

the thrust of the bow. When, however, the chord can be placed at, or a little below the springs of the arch, all danger of this kind may be avoided by simply wedging its ends well against the faces of the abutments.

As to the size of the web members, when a bowstring truss is **fully loaded** on top of the bow, (as is approximately the case with a center and its archstones,) the strains on the web members are quite insignificant, and arise chiefly from the weight of the center itself; **but while it is being so loaded,** they are not only greater, but are constantly changing, not only in amount, but also in character—being at one period compressive, and at another tensile.

Hence it would be very tedious to calculate the dimensions of the web members. Fortunately the necessity for doing so is in a great measure obviated by the fact that a center being but a temporary structure, the timber composing it is not ultimately wasted if a greater quantity of it is used than is absolutely required. Moreover facility of workmanship is secured by not having to employ timbers of many different sizes.

Hence the writer will venture to suggest, entirely as a rule of thumb, to **give each web member half the transverse area of the bow,** taking care to make each of them a **tie-strut.**

Rem. 3. As to details of joints, we refer to the Figs on pages 735, 736; merely suggesting here the use of long and wide iron shoes where timbers are subjected to great pressure sideways.

Rem. 4. To prevent the thrust of the bow when its rise is small, from splitting off the ends of the chords, the two may be united by many more bolts than are employed in roof trusses, &c, where only one is generally placed near each end of the chord. But they may when required be inserted at intervals extending to many feet from the ends. They should have strong large washers; and may have about the same inclination as the shortest web member.

Another way of securing the same end in smaller spans, is by completely encasing the two sides of the bow and chord, to a distance of a few feet from their ends, in short pieces of board or plank spiked to both of them, and having about the same inclination as just suggested for bolts.

Rem. 5. Build up both sides of the arch at once, in order to strain the centers as little as possible.

Rem. 6. When a bridge consists of more than one arch, and they are to be built one at a time, there must be at least two centers; for a center must not be struck until the contiguous arches on both sides are finished, for fear of overturning the outer unsupported pier. Therefore if there are but two arches, they must be built at once, requiring two centers.

Rem. 7. Always use supports either vertical or inclined (and provided with striking-wedges) under the frames, and intermediate of the end supports, when possible; even if they can extend out but a few feet from the abutments, as at the left side of Fig 9.

Rem. 8. The weight of large centers and their lagging is greater for flat arches than for high ones of the same span; and also approaches nearer to that of the supported arch.

Rem. 9. Thickness of lagging. The following table gives thicknesses which will not bend more than an eighth of an inch under the weight of any probable archstones **adapted to the respective spans;** and generally not so much.

TABLE OF LAGGING.—Original.

Distance apart of frames, **in the clear.**	Span of center in feet.					
	10.	**20.**	**50.**	**100.**	**150.**	**200.**
	Thickness of close lagging not to bend more than ⅛ inch.					
Feet.	Ins.	Ins.	Ins.	Ins.	Ins.	Ins.
6	3¼	3⅝	4¼	4¾	5	5¼
5	2½	2⅞	3⅜	3⅝	3⅞	4
4	1⅞	2⅛	2½	2¾	2⅞	3
3	1¼	1⅜	1¾	1⅞	2	2
2	¾	⅞	1	1⅛	1⅛	1¼

With thicknesses three quarters as great as these, the bending may reach a full quarter inch; which may be allowed in dists apart of 3 or more ft.

Rem. 10. Centers are framed, or put together, (like iron bridges) on a firm, level temporary floor or platform, on which a full-size drawing of a frame

first made. As each frame is finished, it is removed to its place on the piers or abuts.

Art. 9. The Wissahickon Bridge of the Reading R R, at Philadelphia, has five arches of 65 ft span, 23 ft rise, 28 ft wide (archstones 3 ft deep, with dressed beds and joints, in cement mortar); with four cutstone piers 9.5 ft thick at top, and from 35 to 50 ft high. It contains about 15400 cub yds of masonry.* **Each center** consisted of 7 frames or trusses of hemlock timber, of the Bowstring pattern, with lattice web-members; and as nearly as may be, of the same span and rise as the arches. They were placed 4.5 ft apart from center to center; and were supported near each end *f*, Fig 13 (a transverse section to scale) by a hemlock post *p*, 12 ins square. **The bow** was of two thicknesses *b b* of hemlock plank, 6 ins apart clear, in lengths of 6 ft, with their upper edges cut to suit the curve of the arch. Each piece was 4 ins thick, by 13.5 ins deep at its middle, and 12 ins at its ends. These pieces did not break joint; but at each joint were four ¾ inch bolts, with nuts and washers, uniting them with chocks or filling-in pieces.

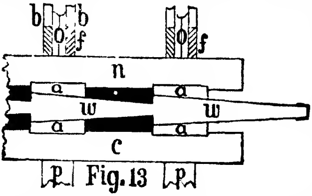

Fig. 13

The bow, *b b*, footed on top of the ends of the chords *f*; and the angle formed by their meeting (seen only in a side view) was (for about 2.5 ft horizontal and 5.5 ft vertical) filled up solid with vertical pieces, to afford a firmer base for resting the frame on *n*; beyond which it extends (in a side view) about 18 ins.

The chords *f* were of two thicknesses of 4 × 12 hemlock plank, 6 ins apart clear, and most of them in two or three lengths, breaking joint, and with two ¾ inch bolts, with nuts and washers, at each joint, for bolting them together, and to filling-in pieces. **The web members** of each frame were 26 lattices, *o*, of 3 × 12 inch hemlock, crossing each other about at right angles, at intervals of about 3.5 ft from center to center, and passing between the two thicknesses *b b* of the bow, and *f f* of the chords. A few of the lattices were in two lengths, and the joints were not at the crossings. The lattices were connected at each crossing by two hard wood treenails 9 ins long, and 2 ins diam; and one such, 18 ins long, passed through the intersection of each end of a lattice with a bow or chord. The first lattice foots about 4 ft from the end of a chord. They do not extend above the top of the bow. All the spaces between the two thicknesses of bow or chord, where not occupied by the ends of lattices, were completely filled by chocks, well spiked.

Each frame contained about 360 cub ft of timber; and weighed about 5 tons. They were very flexible laterally until in place, and braced together by 4 transverse horizontal planks spiked to their chords; and by 5 others above them, spiked to the lattices.

Until the keystones were placed, all the joints of the frames continued tight, under the pressure from the arch, and from the unfinished backing to the height of about 14 ft above the springing line; but after the keystones were set, all the joints of the chords alone opened from .25 to .75 of an inch; and at the same time the lagging under the *haunches* of the arches became slightly separated from the soffit of the masonry.

Each center sank but a full inch at the middle, under the pressure from the arch and 14 ft of backing.

The portion of the bridge above the piers was about two thirds completed before the centers were struck.

There was one wedge *w*, *w*, (32.5 ft long, of 12 × 12 inch *oak*) under each end of a center. It was trimmed to form 7 smaller ones *w*, *w*, each 4.5 ft long, and tapering 7 ins; one under each end of each frame *f*. They played between tapered blocks *a*, *a*, of *oak*, 2 ft long, 1 ft wide, let 1 inch into the cap *c*, or into the piece *n*, on which last the frames *f*, *f*, rested. The sliding surfaces were well lubricated with tallow when put in place.

The wedges were struck with ease, at one end of a center at a time, by an oak log battering-ram 18 ft long, and nearly a ft in diam, suspended by ropes, and swung and guided by 4 men. They generally yielded and moved several inches at the second blow with a 3 or 4 ft swing. Although each wedge was loosened *entirely* within 2 or 3 minutes, thus lowering the centers *very suddenly*, yet on account of the

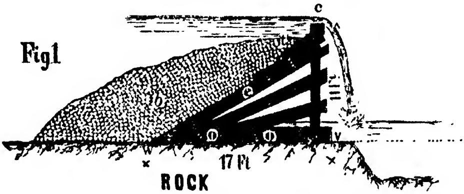
* This bridge, finished without accident, in 1882, reflects much credit on the late William Lorenz, Esq, Ch. Eng; on Mr. Charles W. Buchholz, Assistant in Charge; and on the skilful and energetic contractors, William & James Nolan, of Reading, Penna. These last most cordially assisted the writer in making observations during the entire progress of the work.

good character of the masonry, not the slightest crack of a mortar joint could afterwards be detected in any part of the work. After three days the average sinking of the keystones was only .35 of an inch; the least was ¼: and the greatest ⅝ of an inch. The heads and feet of the posts *p* compressed the hemlock caps *c*, and the sills, about ⅜ of an inch each, showing that for arches of this size the caps and sills had better be of some harder wood, as yellow pine or oak; although probably the compression was facilitated by the large mortices, 3 by 12 ins, and 6 ins deep.

TIMBER DAMS.

Primary requisites, in the erection of dams, are, a foundation sufficiently firm to prevent them from settling, and thus leaking; the prevention of leaks through their backs, or under their bases; and the prevention of wear of the bottom of the stream in front of the dam, by the action of the falling water. For the first purpose, hard level rock bottom is of course the best; and should be chosen, if possible. In that case, thick planks, *tt*, Fig 6, (single or double, as the case may be,) closely jointed, and reaching from the crest, *c*, to the back lower edge *w*, (where they should be scribed down to the rock;) with a good backing, *b*, of gravel, will suffice to prevent leaks. Gravel, or rather very gravelly soil, is far better than earth for this purpose; for if the water should chance to form a void in it, the gravel falls and stops it. To prevent this backing from being disturbed near the crest of the dam, by floating bodies swept along by freshets, a rough pavement of stones, about 15 to 18 inches deep, as shown in Fig 7, should be added for a width of about 10 to 20 feet; or until its top becomes 3 to 5 feet below the crest *c* of the dam, according to circumstances.

Fig 1

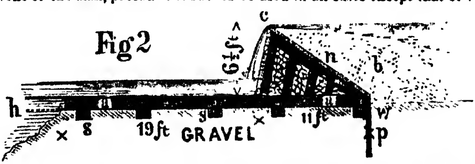


In Fig 1, (a dam on the Schuylkill navigation,) the upper timbers, *e*, are all close jointed, and laid touching, so as not to require planking in addition.

But if the bottom of the stream is gravel or earth, there must in addition to these be used two thicknesses of sheet piles, *p*, Fig 2, &c, close driven, breaking joint, to a depth of several feet, to prevent leaking through the soil beneath the base of the dam. Frequently but one thickness is used. If the bottom is soft or open for a depth of only a few feet, it is at times better to remove it, and base the dam on the firmer stratum below; still, however, using the sheet piles. Old decayed timber and other rubbish should be removed from the base. In very bad soils of greater depth, it may be necessary to support the dam entirely upon a platform resting on bearing piles. Here great precautions are necessary against leaks; but the case occurs so rarely, that we shall not stop to consider it.

As to the wearing away of the bottom of the stream by the water falling over the front of the dam, precautions should be used in all cases except that of very

Fig2



hard rock, or of medium rock protected by a considerable depth of water. The dam, Fig 1, was built upon a tolerably firm micaceous gneiss in nearly vertical strata, covered by about 2 feet of water in ordinary stages. In 30 years the rock was

worn away in front of the dam, as shown in the fig, to the average depth of 3 feet; or very nearly 1 inch per year. The depth of water on the crest c, was usually from 6 to 18 ins, rarely 5 or 6 ft during freshets, and but a few times during the whole period, 8 or 9 ft.

At Jones's dam, on Cape Fear River; height of dam, 16 ft; front vert; fall, usually 10 ft, into 6 ft depth of water, the soft shale rock, in vert strata, was, in the course of a few years, worn away 16 ft, and the dam was undermined to such an extent as to fall into the cavity

In another case, dam 36 ft high, front vert; the water falling upon nearly vert strata of hard shale rock, usually covered by but about 2 ft of water, in about 20 years wore it to an irregular depth of from 10 to 20 ft, and extending from the very face of the dam, to 70 or 80 ft in front of it.

In Fig 2, upon a stream subject to very violent freshets, the gravel was washed away for a considerable width and depth beyond the apron, as at *h*. To prevent a repetition, the cavity was filled with cribwork full of stone, clear across the river.

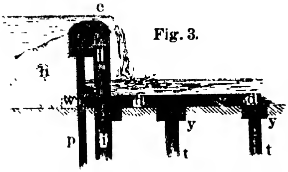


Fig. 3.

A deposit of blocks of loose stone, of even a ton weight or more, will not serve as a protection in front of a dam exposed to high freshets, but will soon be swept away. A common precaution against this wear, in low dams, is an *apron*, *a a*, Fig 2, or *d d*, Fig 3; of either rough round tree trunks, or of hewn timber, laid close together; extending under the entire base of the dam, and from 15 to 30 ft in front of its face. These are sometimes bolted to pieces, *s s*, Fig 2, or *y y*, Fig 3; laid under them across the stream. In Fig 3, with very soft bottom, these pieces *y y* are supposed to be bolted to short piles *t t*, driven for that purpose.

At times a distinct wide low timber crib, filled with stone, and covered on top with stout plank has been placed in front of the dam, to receive the fall of the water, and is effective in protecting the bottom. Also in some cases, a dam of less height, and of cheap character, has been built at a short distance down stream from the main one, in order to secure at all times a deep pool in front of the latter for breaking the force

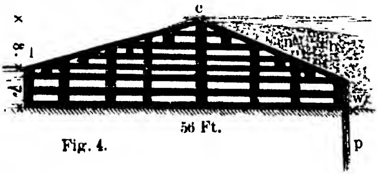

Fig. 4.

Another precaution is to substitute a sloping front like *c l*, Fig 4, or such as Figs 1 and 2 would form if reversed, for the nearly vert one of the other figs, thus to some extent reducing the force of the water. This, however, is but a partial remedy, especially for soft bottoms in shallow water, for the sliding sheet still descends with great force. The best form of dam, perhaps, in such cases, is that shown in Fig 5, in which the front consists of a series of steps of about 1 vert, to 3 or 4 hor. These effectually break the force of the water, and, with the addition of an apron *o o*, secure a satisfactory result. It is objected against this form, as also against Figs 4 and 6, that their fronts are liable to be torn by descending trees, ice and other bodies swept along during freshets, but experience shows that this objection has but little weight, for when such bodies pass, the sheet of water is thicker than usual; and protects the front timbers. On the Sch Nav, the timbers *c l*, Fig 6, scarcely wear thin at the rate of an inch in 10 to 15 years.

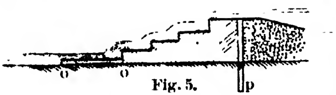

Fig. 5.

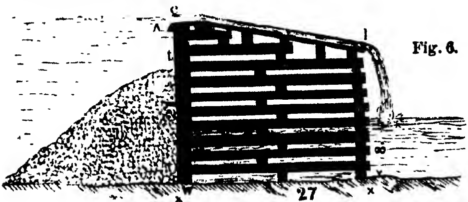

Fig. 6.

The forms of wooden dams are many; (see the figs, which show those most used,) varying with the circumstances of the case, and with the fancy of the designer. In the United States they are usually of cribwork, of either rough round logs with the bark on, or of hewn timber; in either case about a foot through. These timbers are merely laid on top of each

ther, forming in plan a series of rectangles with sides of about 7 to 12 ft. They are not notched together, but simply bolted by 1 inch square bolts (often ragged or jagged) about 2 to 2½ feet long, through two timbers at every intersection. These are not found to rust or wear seriously, even when exposed to a current. Square bolts hold best. Round logs are flattened where they lie upon each other. Experience shows that former but more expensive connections are entirely unnecessary. The cribs are usually, but not always, filled with rough stone. In triangular dams, disposed as in Figs 1, 2, and 7, this stone filling is not so essential as in other forms, because the weight of the water, and of the gravel backing, tends to hold the dam down on its base. Still, even in these, when the lower timbers are not bolted to a rock bottom, or otherwise secured in place, some stone may be necessary to prevent the timbers from floating away while the work is unfinished, and the gravel not yet deposited behind it. On rock, the lowest timbers are often bolted to it, to prevent them from floating away *during construction*, and when the water is some feet deep, this requires coffer-dams. Or, the cribs may be built at first only a few feet high; then floated into place, and sunk by loading them with stone, for the reception of which a rough platform or flooring will be reqd in the cribs, a little above their lowest timbers. The bolting to the rock may then be dispensed with. The water may flow through the open cribwork as the building higher goes on; attention being paid to adding stone enough to prevent it floating away if a freshet should happen. Or, cribs shown in plan at *c c*, Fig 8, loaded with stone, may be sunk, leaving one or more intervals like that at *o o o o*, between them, for the free escape of the water. These openings to be finally closed by floating into them closing cribs shaped like *n*.

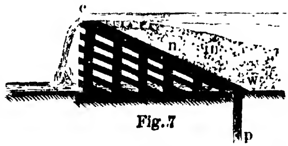

Fig.7

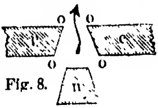

Fig. 8.

The workmanship of a dam in deep water can of course be much better executed in coffer dams, than by merely sinking cribs. The joints can be made tighter, the stone filling better packed; the sheet piling more closely fitted, &c.

When a very uneven rock bottom in deep water, or the introduction of sluices in the dam, or any other considerations, make it expedient to build dams within coffer dams, both should be carried on *in sections*; so as to leave part of the channel-way open for the escape of the water. Commencing at one or both shores, the first section of the coffer dam may reach say quarter way or more across the stream. In the section of the dam itself built within this enclosing coffer-dam, ample sluices should be left for the water to flow through when we come to build the *closing* section of the coffer-dam. When the dam has been finished, these sluices may be closed by **drop-timbers***. Before removing one section of coffer dam, the outer end of the enclosed section of dam itself must be firmly finished in such a manner as to constitute a part of the inner end of the next section of coffer dam. It is impossible to give details for every contingency; the engineer must rely upon his own ingenuity to meet the peculiarities of the case before him. In some cases of shallow water, mere mounds of earth may answer for coffer dams, or rough stone mounds backed with earth or gravel.

After the water has passed beyond the crest, *c* in the figs, there is no necessity for preventing its leaking down among the crib timbers; on the contrary, the thick sheeting planks, (or squared timbers, as occasion may require) *c l*, Figs 4 and 6, which form the slopes along which the water then flows in some dams, are usually not laid close together, but with open joints of about ½ inch wide between them, for the express purpose of allowing part of the water to fall through them, so as to keep the timbers beneath them partially wet, which, to some extent, renders them more durable. In Figs 1, 4, 6, and 7, the water of the lower pool flows freely back among the crib timbers, and rough quarry stones with which the cribs are filled either partly or entirely. In Figs 4 and 6, these stones are not shown. In the dam, Fig 1, none were used. In Fig 2 they were as shown.

A substantial, and not very expensive dam of the form of Fig 7, may be built of rough stone in cement. Some hewn timbers should be firmly built horizontally into the masonry of the sloping back *c n w*, at a few feet apart, with their tops level with the surf of the masonry. To these must be well spiked close-jointed sheeting-plank *c n w*, for protecting the masonry from the action of the water, and of floating bodies. The gravel backing *b*, may be omitted, but the sheet piles *p*, and an apron in front of the dam, will be as indispensable in yielding soils, as if the dam were of timber.

Figs 1, 2, 4, 6, and 7, are sections drawn to a scale, of existing dams in Pennsylvania, that have stood successfully the force of heavy freshets for a long series of years †. These freshets at times carry along large bodies of ice, trees, houses, bridges, &c., and have risen to 11 ft above the crests. Fig 1, on the Sch Nav was built in 1819, and served perfectly for 39 years, until in 1858 the decay of much of its timber, especially of the close-laid top ones, *e*, rendered it necessary to build a new one just in front of it. It was of extremely simple construction, and was never filled with stone. The bottom timbers, *o o*, 10 ft apart, were bolted to the rock; and immediately over each of them, was such a series of inclined timbers as is shown in the fig. The top ones, *e*, however, were close jointed and laid touching so as to form the top sheeting, instead of thinner planks. The short pieces at *t* were laid in the same way. No coffer dam was used, but the bottom pieces were first bolted to the rock, 10 ft apart, then the stringers and the sloping pieces were added. The close covering (*e*) was carried forward from each end of the dam, until at last a space of only about 60 ft was left in the center, for the water to pass. The close covering for this space being then all got ready, a strong force of men was set to work, and the space was covered so rapidly that the river had not time to rise sufficiently high to impede the operation.

* Timbers ready prepared for closing an opening through which water is flowing; and suddenly *dropped* into place by means of grooves or guides of some kind for retaining them in position. Several such timbers may at times be firmly framed together, and then be all dropped at once; closing the opening or sluice at one operation, especially when it is of small size. In some cases, a crib may be sunk on the up-stream side of such an opening, for closing it.

† Those on the Schuylkill Navigation were obligingly furnished by James F. Smith, Esq, chief engineer and superintendent of that work. Other valuable information from the same source will be found in different parts of this volume.

Fig 2 is a canal feeder dam on the Juniata. Here *s s* are timbers stretching clear across the stream, (about 800 ft.) and sustaining the apron *a a*, of stout hewn timbers laid touching. This dam was filled with stone, for the retention of which the front sheeting planks were added.

Fig 6 is on the Sch Nav, was built in 1855 It is a form much approved of on that work, for such situations, namely, firm rock foundation, with a considerable depth of water in front. The highest dam (32 ft) on the Sch Nav, is very similar to it, built in 1851. All the dams on this work are of hewn timber, chiefly white and yellow pine. The water occasionally runs from 8 to 12 feet deep over their crests, and then overflows and surrounds many of the abuts. The vertical back allows the overflowing water to leak down among *all* the lower timbers of the dam, and thus tend to their preservation

Fig 4 shows the dams on the Monongahela slackwater navigation, W. Milnor Roberts, eng. They are of round logs, with the bark on, flattened at crossings. The longest ones in the fig are 10 feet apart along the length of the dam Experience shows that such dams possess all the strength necessary for violent streams. On rock, the lowest timbers are bolted to it

Fig 7 has been successfully used to heights of 40 ft *

Fig 3 is intended merely as a hint for a very low dam on yielding bottom Its main supports are piles *i i*, from 4 to 8 ft apart, according to the height of the dam, and other circumstances, and *t t* are short piles for sustaining the apron *d d* It may be extended to greater heights by adding braces in front, which may be covered by stout planks to form an inclined slide for the overfalling water. Many effective arrangements of piles and sloping timbers for dams on soft ground, will suggest themselves to the engineer Thus, at intervals of several feet, rows of 3 or more piles may be driven transversely of the dam, the top of the outer pile of each row being left at the intended height of the crest, while those behind are successively driven lower and lower, so that when all are afterward connected by transverse and longitudinal timbers and covered by stout planking, and gravel, they will form a dam somewhat of the triangular form of Fig 7. It would be well to drive the piles with an inclination of their tops up stream

There is much scope for ingenuity both in designing, and in constructing dams under various circumstances, and in turning the course of the water from one channel to another, by means of ditches, pipes, or troughs, &c, at diff heights, aided at times by low temporary dams or mounds of earth, or of sheet piles, &c, or by coffer dams, so as to keep it away from the part being built Each locality will have its peculiar features, and the engineer must depend on his judgment to make the most of them

Abutments of dams as a general rule should not contract the natural width of the stream, or, if they must do so as little as possible, for contractions increase the height, and violence of the overflowing water in time of freshets, during which a great length of overfall is specially desirable They should be very firmly connected with the ends of the dams; and should, if the section of the valley admits of it be so high, and carried so far inland that the high water of freshets will not sweep either over them, or around their extremities, and thus endanger undermining, and destruction. In wide, flat valleys they cannot be so extended without too much expense and the only alternative is to found them so deeply and securely as to withstand such action, making their height such that they will, at least, be overflowed but seldom Their ends adjacent to the dam should be rounded off, so as to facilitate the flow of the water over the crest

They are best built of large stone in cement, for although sufficient strength may be secured by timber, that material decays rapidly in such exposures. If of earth only, they are very apt to be carried away if a freshet should overtop them.

Sluices should be placed in every important dam, in order that all the water may be drawn off if necessary, for the purpose of repairs; or of removing mud deposits; or finding lost articles of importance, &c They may be merely strong boxings, with floor, sides, and top of squared timbers, and passing through the breadth of the dam, just above the bottom. To prevent trees, &c, from entering and sticking fast in them, some kind of strong screen is expedient. In common cases a sluice should not *exceed* about 3½ ft by 5 ft in cross section; otherwise it becomes hard to work Two or more such openings may be used when much water is to be voided. They should be near the abutments. The gates or valves for opening and shutting them, should be at the up stream end; for if at the lower one, accumulations of mud, &c, will fill the sluices, and prevent them from working They are usually of timber, and slide vertically in rebates, being raised and lowered by rack and pinion, but in very important dams they may be of cast iron Two sets of sluices are desirable that one may be always ready for use if the other is stopped for repairs

The part of the apron in front of the sluice should be particularly firm, so as not to be deranged by the water rushing out under a high head.

In dams of masonry and of concrete, if the shores are of rock, **the plan** is frequently given the form of a **flat arch**, convex up-stream. By thus utilizing the banks as abutments for the (horizontal) arch, material reduction of the volume of material in the dam may properly be effected; but, unless the banks are of rock, they afford but imperfect abutments for the arch; and they are exposed to wear by the current thrown against them at its ends.

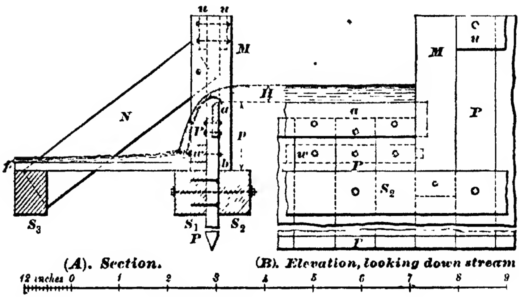
A dam, built obliquely across a stream, will have less depths of water upon its crest than one built normally to the current, and will therefore flood adjacent country to a less extent. Other things equal, the less the slope of the stream, the further will the flood heights extend up stream.

---

* **Cost of crib dams.** With common labor at $1.50 per day; lumber, $20 per 1000 ft. board measure, delivered; stone for filling, $1 per cub. yard; gravel 50 cents per cub. yd.; iron for bolts etc., 2 cts. per lb.,—such dams in shallow water usually cost, complete, $2.48 to $3.24 per cubic yard of crib.

Figs. 9 and 10 are **designs for small measuring weirs**, suitable for shallow streams up to say 100 feet wide; Figs. 9 for earth or gravel bottom, and Figs. 10 for rock.

In the former, the 8 × 10 inch hemlock sills S_1 and S_3 are first laid across the bottom of the stream, which is trenched where necessary, care being taken to lay S_1 in a true line. The sills should extend say from 5 to 10 feet into each bank of the stream. Tongued and grooved sheet piling P, of 3 × 10 inch hem-



Figs. 9.—Measuring Weir on Earth or Gravel Bottom.

lock, is then driven close behind the upper sill S_1 to a depth of from two to four feet, and spiked to S_1. A third sill, S_2, of the same length as S_1 and S_3, is then laid behind the sheet piling, and the two sills S_1 and S_2 and the sheet piling P are then secured together, as shown, by 1 inch bolts, spaced about 2 feet apart. The tops of the sheet piling project about a foot above the sills, and are stiffened by 4 × 4 inch timbers *w*, bolted in front of them and resting upon the flooring *f* of 2 × 10 inch spruce. This flooring, like the sills, extends several feet beyond each end of the weir into the bank, and is there loaded to its full capacity with heavy stones. Any spaces left underneath it by unevenness of the bottom should also be leveled up with stones or gravel.

A 10 × 10 inch yellow pine post M, 3 feet high, is tenoned between sills S_2 and S_1 at each end of the overflow, and braced by an 8 × 10 inch yellow pine strut N, tenoned to it and to the sill S_3. Beyond these posts the sheet piling P extends as high as the top of the posts, and is carried, at that height into the bank; the tops of the piles being held in line by two 2 × 8 inch waling pieces *u u* bolted to them, one on each side.

In Figs. 10, the hemlock sills, S_1 of 10 × 10 inch, and S_2 of 6 × 8 inch, rest upon a Portland cement masonry wall, of varying height to accommodate the inequalities of the rock bottom; and are secured to it by 1 inch bolts spaced about 4 feet apart. These bolts pass down through the masonry, as shown, and a foot or more into the rock below.

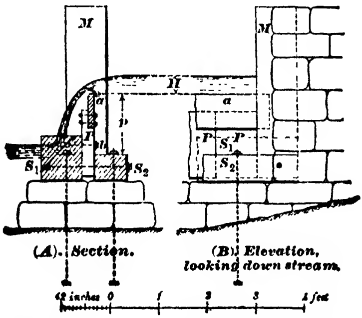
Between the two sills are bolted upright 3 × 10 inch tongued and grooved hemlock planks P, 15 inches long. At each end of the weir, a 10 × 10 inch yellow pine post M is tenoned between the sills, as in Figs. 9, and built into the masonry ends of the dam, which last extend well into the banks of the stream.

In both Figs. the crest-piece *a*, is of 2 × 8 inch oak, beveled so as to leave a horizontal top face ¼ inch wide. The crest-piece is let in flush with the back of the piles or boards P, to which it is bolted, and is let into the end posts M about 2 or 3 inches. At low stages of water, the flow may be confined to a *portion* of the length of the overfall by flash-boards placed along the rest of the dam.

A crest-piece made of 8 × ¼ inch bar iron is preferable to one of wood. It requires of course much less cutting away of the sheet-piling, and its upper edge is less subject to abrasion by drift passing over the weir. The top edge, and the abutting ends of the several lengths, should be planed smooth and square; the former

to insure a sharp inner corner at *a* for the water to pass over, and the latter in order to avoid leakage. As a further precaution against leakage, a strip or butt-strap of 8 × ⅛ inch iron, about a foot long, may be let in, *between the crest-piece and the sheet piling*, opposite each joint of the former, and overlapping both the adjoining ends, the piling being cut away ⅛ inch deeper at those points, in order to accommodate them. Such butt-straps, if placed on the *up*-stream side of the crest-piece, would break the continuity of the sheet of water passing over the weir, and thus interfere somewhat with the correctness of the gauging. Such iron is obtainable in any commercial center, in lengths of about 16 feet. 8 × ¼ weighs 6⅔ pounds per running foot; 8 × ⅛, 3⅓ pounds.

All the joints should be caulked with oakum. To apply the usual weir formulæ (see Art. 14 *f*, p. 548) the back of the weir should be vertical for a depth *p* below



Figs. 10.—Measuring Weir on Rock Bottom.

the crest *a* equal at least to twice the head H on the weir. It is therefore better to protect the back of the weir by tarpaulin rather than resort to puddling, except close to the bottom.

In a long weir with a low fall, it is difficult to secure a sufficiently free access of air to the space behind the falling sheet of water, especially when the stream is low and the sheet tends to hug the face of the dam. In such cases a partial vacuum * forms between the falling sheet and the face of the dam, and increases the discharge, thus vitiating the results. It is therefore important, in designing measuring weirs, to arrange (as far as possible) so that the sheet of water may fall clear through the entire distance between the up-stream and down-stream levels without striking any portion of the weir itself, for such striking would diminish the clear space behind the sheet and increase the difficulty of preventing a vacuum there.

* Such a vacuum causes the down-stream water near *w*, Figs. 9, to rise behind the sheet. When the rarefaction of the air behind the sheet has proceeded to a certain extent, the external air breaks in and relieves the vacuum. Then another vacuum forms, and is in turn relieved, and so on, alternately. At such times it has been noticed that light bodies, such as chips, etc., floating in the down-stream water near the ends of the weir, are drawn into the space behind the sheet and carried toward the middle of its length, and then in turn ejected at the point where they entered, thus traveling back and forth along the space behind the sheet.

Tremblings in Dams. Dams over which the water falls in a long, smooth, unbroken sheet of considerable height, are more or less subject to tremblings, caused apparently by alternate compression and rarefaction of the air by the falling sheet, especially in the space (W, Fig 20, p. 547) behind the sheet, where a partial vacuum is often formed, because the air there is entangled in the falling water and given off again by it down stream in the shape of foam. Such tremblings sometimes cause a rattling of windows half a mile or more away. We have known this to be stopped (in one case unintentionally) by building a well-covered wide crib apron, a few feet high against the front of the dam, for preventing the abrasion of the bottom. In other cases a series of oblique timbers placed against the front of the dam, and part way up it, at a slope of about 1½ to 1, and covered with plank, has been perfectly effective in stopping it. In short, any device which admits air more freely behind the falling sheet, or destroys the continuity of the latter (such as flash boards of different heights or placed at intervals along the crest), or which reduces its height and its continuous length, ought to diminish or obviate the trouble.

The proper time for building dams is of course at the longest period of low stage of water.

Table of thickness of white pine plank required not to bend more than $\frac{1}{240}$ part of its clear horizontal stretch, under different heads of water. (Original.)

Stretch in Ft.	Heads in feet. 40	30	20	10	5
	Thickness in Inches.				
3	3½	3	2¾	2¼	1¾
4	4½	4	3½	2¾	2¼
6	6¾	6	5¼	4¼	3¼
8	9	8	7	5½	4½
10	11¼	10	8¾	7	5½
12	13½	12¼	10¾	8½	6¾
15	16¾	15	13	10½	8⅓
20	22⅓	20	17⅓	14	11

WATER SUPPLY.

Consumption of water. Owing largely to the proper extension of the use of water in dwellings, the quantity required in cities increases faster than the population. In other words, the per capita consumption increases.

Use. Abundant experience shows that a supply of 50 gallons (or say 7 cubic feet) per capita per day is abundant for all the needs and luxuries of well-to-do families in American cities. The manufacturing consumption, of course, bears no fixed relation to the population. In cities it is generally much less than the domestic consumption.

Waste. In American cities, the waste often amounts to two or three times the quantity really used. Of the 116 gallons per capita per day, delivered in New York in 1899, Mr. Freeman* estimates that from 31 to 56 gallons were used, 10 unavoidably wasted, and from 50 to 75 avoidably wasted.

In Philadelphia, investigations by means of the Deacon waste-water detector, on 142 modern seven-room, two-story dwellings, with bath, etc., on two intermediate streets, showed that, of 222 gallons per capita per day, furnished through 782 fixtures, 192 gallons, or 86.5 per cent. were wasted, and only 30 gallons, or 13.5 per cent. were used. The City has built extensive works for the purpose of pumping, filtering, conveying, repumping, storing, and distributing the water wasted, as well as the smaller quantity used. Of the total cost,† less than half would have sufficed for the water used and unavoidably wasted.

Sources of waste. The waste is caused by heedlessness; by allowing water to run to waste in order to prevent it from freezing in winter and in order to get cooler water in summer; by leaky and otherwise defective fixtures; by unsuspected leaks in mains and service pipes, etc.

As a "guess, tempered by judgment," Mr. Freeman* classifies the 50 to 75 gallons per capita per day, wasted in New York, as follows:

Leaks in mains	10 to 15	gals per capita per day.		
" service pipes	10 to 15	"	"	"
" defective plumbing	15 to 25	"	"	"
Careless and wilful waste	14 to 17	"	"	"

The avoidable waste is usually perpetrated by a small fraction (say from one-fifth to one-third) of the population, the remainder using water reasonably. In the Philadelphia case, above cited, of the 782 fixtures, 22 were found to be "leaking slightly," and 32 "turned on continually."

Waste restriction. Water meters. Waste is best restricted by making its avoidance a pecuniary object to the consumer; and this is best accomplished by the use of the water meter, at least on all services (domestic, industrial, and public) where waste is found to be going on. The meters should be owned and maintained by the corporation supplying the water.

Minimum charge. In order to encourage the liberal *use* of water, while discouraging its *waste*, and thus avoid undue economy (tending to uncleanliness) each consumer should be charged a minimum periodical rate, sufficient to cover amply all the water he can possibly use and enjoy.

Mr. Freeman* estimates the average cost of domestic meters, for New York and Brooklyn, mostly 5-8 inch and 3-4 inch, with a few of larger sizes, at $12.50 each, and the cost of installation by the city, working systematically and on a large scale, at $2.50 each, or a total of $15.00 each. He assumes "the average life of the ordinary domestic meter, of a good type, well cared for, and with occasional repairs and renewal of worn parts," at "not far from 20 years"; and annual expenses as follows:

	Providence, R. I. Actual, approx.	New York. Assumed.
Interest on cost of meter and setting	$0.50	$0.45
Depreciation and renewal of meter (life assumed 20 years)	0.75	0.75
Maintenance and repairs, testing and resetting	0.46	0.70
Reading meters and computing bills	0.42	0.60
Total annual cost, per meter	$2.13	$2.50

* Report upon New York's Water Supply, made to Bird S. Coler, Comptroller, by John R. Freeman, Civil Engineer, 1900.

† The total cost approximates $30,000,000.

Free water for fire protection. Cities sometimes give to manufacturers a free supply of water through special connections, to be used for fire protection only; the manufacturer giving bond not to use such connection for any other purpose, and the city placing a meter on the connection for the detection of any illicit use of the water for other purposes.

Water for city use should not be drawn from the very bottom of the reservoir, because it will then be apt to carry along the sediment; which not only injures the water, but creates deposits within the pipes; thus obstructing the flow. In fixing upon the necessary capacity of a reservoir, this must be taken into consideration; inasmuch as all the water below the level for drawing off, must be regarded as lost. When circumstances justify the expense, it is well to curve up the reservoir end of the service main, so as to provide it with valves at different heights; for drawing off only the purest stratum that may be in the reservoir. With this view, the valve-tower generally has such valves communicating with the water in the reservoir; and by this means only the purest is admitted into the tower: and from it, into the city pipes. This refinement, however, is rarely practicable. Such valves must of course be worked by watchmen.

Art. 1. Reservoirs. In important reservoirs of earth, for storing water to moderate depths for cities, experience appears not to sanction **dimensions** *bolder* than 10 feet thick at top; inner slope 2 to 1; outer slope 1½ to 1.* A top width of 15 feet to 20 feet, and inside slopes of 3 to 1, are adopted in some important cases; with outer slopes of 2 to 1. Both slopes, however, are at times made only 1½ to 1. The level water surface should be kept at least 3 or 4 feet below the top of the embankment; or more, if liable to **waves.** In a large reservoir, a quite moderate breeze will raise waves that will run 3 feet (measured vertically) up the inner slope. A low wall, or close fence, *w*, Fig 37, is sometimes used as a defence against them. The top and the outer slopes should be protected at least by sod or by grass. To assist in keeping the top dry, it should be either a little rounding, or else sloped toward the outside.† The soft soil and vegetable matter should be carefully removed from under the entire base of the embankments; which should be carried down to soil itself impervious to water, in order that leakage may not take place *under* them. To aid in this, a double row of sheet piles, or a sunk wall of cement masonry, carried to a suitable depth below the bottom may be placed along the inner toe in bad cases. If there are springs beneath the base, they must either be stopped, or led away by pipes. The embankment should be carried up in layers, slightly hollowing toward the center, and not exceeding a foot in thickness; and all stones, stumps, and other foreign material, such as *clean* gravel, sand, and decomposed mica schists, &c, that may produce leakage, carefully excluded. These layers should be well consolidated by the carts; and the easier the slopes are, the more effectively can this be done. The layers, however, should not be distinct, and separated by actual plane surfaces; but each succeeding one should be well incorporated with the one below. This has sometimes been done by driving a drove of oxen, or even sheep, repeatedly over each layer; in addition to the carting. Rollers are not to be recommended, as they tend to produce seams between the layers. This might possibly be obviated by projections on the circumference of the roller.

Gravelly earth is an excellent **material,** perhaps the best. The choicest material should be placed in the slope next to the water; and should be deposited and compacted with special care in that portion, so as to prevent the water from leaking into the main body of the dam, and thus weakening it. It is not amiss to introduce a bench, *b*, Fig 37, in the outer slope, to diminish danger from rainwash by breaking the rapidity of its descent.

If the bottom of the reservoir itself is on a leaky soil, or on fissured rock, through the seams of which water may escape, it must be carefully covered with from 1½ to 3 feet of good puddle; which, in turn, should be protected from abrasion and disturbance, by a layer of gravel; or of concrete, either paved or not, according to circumstances.

---

* The writer suggests that a top width equal to 2 feet + twice the square root of the height in feet, will be safe for any height whatever of reservoir properly constructed in other respects.

† Some engineers slope the top toward the *inside.*

Reservoirs constructed with the foregoing dimensions, and with care, *may* remain safe for an indefinite period; but where serious damage would result from failure, the following **additional precautions** should be taken. The inner slopes should be carefully faced up to the very top, with at least a close dry rubble-stone pitching, not less than 15 to 18 inches thick; as a protection against wash, and against muskrats. These animals, we believe, always commence to burrow under water. If the slopes are much steeper than 2 to 1, this dry pitching will be apt to be overthrown by the sliding down of the softened earth behind it, if the water in the reservoir should for any cause be drawn down rather suddenly. It will be much more effective, but of course more costly, if laid in hydraulic cement; and still more so if laid upon a layer a few inches thick of cement and-gravel concrete; especially if this last be underlaid by a layer about 1½ to 3 feet thick of good puddle, spread over the face of the slope; the great object being to protect the inner slope from actual contact with the water. If this can be effectually accomplished, slopes as steep as 1½ to 1 will be perfectly secure; for the danger does not arise from any want of weight of the earth for resisting overthrow. **Special care should be bestowed upon the inner toe of the slope.** to prevent water from finding its way beneath it, and softening the earth so as to undermine the stone pitching. Near the top reference should be had to danger of derangement by ice, frost, rain, and waves. Flat inner slopes tend not only to prevent the displacement of the pitching; but increase the stability of the embankment, by causing the pressure of the water (which is always at right angles to the slope) to become more nearly vertical, and thus to hold the embankment more firmly to its base than if there were no water behind it. Sometimes the toes of both the inner and outer slopes abut against low retaining-walls in cement. This gives a neat finish, and tends to preservation from injury.

Many engineers, in order to prevent leaking, either through or beneath the embankment, construct a **puddle-wall**, *p*, Fig 37, of well-rammed impervious soil, (gravelly clay is the best.) reaching from the top to several feet below the base. This wall should not be less than 6 or 8 feet thick on top, for a deep reservoir; and should increase downward by *offsets* (and not by slopes or batters) at the rate of about 1 in total thickness, to 3 or 4 in depth. Other engineers object to these puddle-walls, and contend that leakage should be prevented by making both the inner slopes and the bottom of the reservoir water-tight, by means of puddle, concrete, and stone facing in cement, as just alluded to. They argue that if the embankment is well constructed, it is itself a puddle-wall throughout.

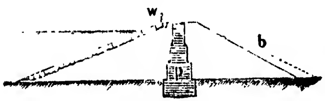


Fig. 37.

Near San Francisco, Cal. are two earthen reservoir dams built about 1864 one 95 feet high, 26 on top inner slope 2.75 to 1, outer 2.5 to 1. The other 93 high, 25 on top, inner slope 3.5 to 1, outer 3 to 1. In each the puddle-wall is carried 47 feet deeper than the base. No stone facing.

It is difficult to prevent water under high pressure from finding its way through considerable distances along seams where earth is in contact with smooth rock, wood, or metal; as, for instance, along the surfaces of iron pipes laid under reservoir embankments; or along the tie-rods sometimes used through the puddle of coffer-dams; and the same is apt to occur under the bases of embankments which rest on smooth rock. Special care should be taken that the earth used in such positions is not of a porous nature; and that it is thoroughly compacted all along the seam; and the straight continuity of the seam should be interrupted or broken as frequently as possible by projections. Faucets or flanges do this to a limited extent in the case of iron pipes; and something similar, but on a larger scale, should at short intervals be constructed in the shape of collars or yokes of cement stonework, in the case of rock or masonry.

It is usually advisable to **divide reservoirs into two parts**, so that while the water in one part is being drawn off for use, that in the other may purify itself by settling its sediment. Also, one part may remain in use, while the other is being cleaned or repaired. Many days, or even two or three weeks, sometimes, are required for the complete settlement of the very fine clayey particles in muddy water; depending on the depth of the reservoir. One or more flights of steps to the bottom of the reservoir should be provided.

Mud in Reservoirs. The reservoirs of the New River Water Co, London, England, were uncleaned for 100 years, during which mud 8 feet deep was

deposited, or about an inch annually. At Philadelphia it is about 25 inch per annum from the Schuylkill, and 1 inch from the Delaware River. At St Louis, Missouri, about 3 to 4 feet per year! Vegetation is apt to take place in shallow reservoirs and near the edges of deep ones, especially in very warm weather; and the plants, on decaying, injure the water.

Water flowing through marsh lands is sometimes unfit for drinking purposes. That, for instance, in some sections of the Concord River, Massachusetts, was reported by the eminent hydraulic engineer, Loammi Baldwin, of Boston, to be absolutely *poisonous* from this cause.

The construction of a large deep reservoir is not only a very costly, but a very hazardous undertaking. With every watchfulness and care, it is almost impossible entirely to prevent leaking; although this may not manifest itself for months, or even years. Should a break occur, especially near a city, it would probably be attended by great loss of life and property. If the water once finds its way in a stream, either across the unpaved top, or through the body of the embankment, the rapid destruction of the whole becomes almost certain.

Art. 1a. Storing Reservoirs. The entire annual yield of a stream may be much more than sufficient for supplying a certain population with water; and yet in its natural condition the stream may not be available for this purpose, because it becomes nearly dry in summer, when water is most needed; while, at other seasons, the rains and melted snows produce floods which supply vastly more than is required; and which must be allowed to run to waste. A storing reservoir is intended to collect and store up this excess of water, so that it may be drawn off as required during the droughts of summer, and thus equalize the supply throughout the entire year. This, when the locality permits, is effected by building a dam across the stream, to form one side of the reservoir, while the hill-slopes of the valley of the stream form the other sides. The stream itself flows into this reservoir at its up-stream end. When the stream is liable to become nearly dry during long summer droughts experience shows that the **capacity** of the reservoir should be equal to from 4 to 6 months' supply, according to circumstances. During the construction of the dam, a free channel must be provided, to pass the stream without allowing it to do injury to the work. If the dam were built precisely like Fig 37, entirely of earth, it would plainly be liable to destruction by being washed away in case the reservoir should become so full that the water would begin to flow over its top. To provide against this we may, by means of masonry, or of cribs filled with broken stone, or otherwise, construct either the whole, or part of the dam, to serve as an **overfall**, or a **waste-weir.** Or a side channel (an open cut, pipes, or a culvert, &c) may be provided at one or both ends of the dam, and in the natural soil, at such a level as to carry away the surplus flood water before it can rise high enough to overtop the earthen dam. Besides these, and the pipes for carrying the water to the town, there should be an outlet, with a valve or gate, at the level of the bottom of the reservoir; in order that, if necessary for repairs, or for cleaning by scouring, all the water may be drawn off. The entrances to the city pipes should be protected by gratings, to exclude fish, &c.

To facilitate repairs or renewals of all valves, &c, which are under water, the reservoir ends of the pipes or culverts to which they are attached, may be surrounded by a water-tight box or chamber, which will usually be left open to the reservoir; but may be closed when repairs are required. Access may then be had to them by entering at the outer end, after the water has flowed away from inside. In case the outlet is through a long line of pipes which cannot thus be entered, a special entry for this purpose may be cast in the pipe itself, near the outer toe of the embankment; to be kept closed except in case of repairs. Sometimes a better, but more expensive means of access to such valves, is secured by enclosing them in a **valve-tower** of masonry. This is a hollow vertical water-tight chamber, like a well; but near the toe of the inner slope; having its foundation at the bottom of the reservoir; whence the tower rises through the water to above its surface. This chamber is provided with valves or gates usually left open to the reservoir; but which may be closed when repairs are needed; and the water in the tower allowed to escape from it through the open valves of the outlets. This done, workmen can descend through the tower by ladders from the aperture at its top.

At times the outlets for the discharge of surplus flood water are, like those for scouring, placed at, or just above, the level of the bottom of the reservoir. In order that these may work in case of a sudden flood at night, &c, they must be furnished with self-acting valves, which will open of their own accord when the flood is about to rise too high. This may be effected by attaching them to floats, the rising of which, when the water is high, will pull them open. All such outlets should be large enough to let men enter them for repairs. They should by

no means be laid through the artificial earthen body of the dam itself, without being supported upon masonry reaching down to a firm natural foundation; otherwise they are very apt to be broken by the subsidence of the embankment. It is usually safer to carry them through the firm natural soil near one end of the dam. Their valves, if only single, should be at their inner or reservoir end, so as to leave the outlets themselves usually empty, for inspection; but it is better to have two valves, so that one may be used when the other needs repair; and in this case one may be placed at each end. Reservoirs which are supplied by pumps, need no precautions against overflow; because the pumping is stopped when they are filled to the proper height. Large storing reservoirs necessarily submerge more or less land, which has therefore to be purchased. By intercepting the descending water, they frequently prevent spring floods from injuring low lands farther down stream. If there are mills down stream from the reservoir, they would evidently be deprived of water for driving them, unless a portion of that stored in the reservoir be devoted to that purpose. Water thus applied to *compensate* for the loss of the natural stream, is called **compensation water**; and the reservoir, a *compensating* one.

Art. 1b. Distributing reservoirs. Frequently a valley fit for a storing reservoir can be found only at a long dist (sometimes many miles) from the town; and it then becomes expedient to construct also an additional one of smaller size than the storing one, near the town; and at as great an elevation above it as circumstances will permit; but lower than the storing one. This is called, by way of distinction, a *distributing* reservoir, because from it the water, after having flowed into it from the storing reservoir, through the long *supply pipe* which connects them, is distributed in various directions through the town, by means of the street mains, or pipes. This small reservoir should hold a supply sufficient at least for a few days; a few weeks would be better; and the end of the supply pipe which terminates in it, should be provided with a valve for shutting off the supply from the storing reservoir. These precautions permit repairs to be made along the line of supply pipe without depriving the town of water in the mean time. With a view to such repairs; as well as to scouring out sediment from the supply pipe, this last should be provided with **outlet valves** at various low points along the entire interval between the two reservoirs; especially at those at which the valves may disch into natural watercourses. On opening these valves, the out rush of the water carries away sediment; and leaves the pipe empty for inspection

In fixing upon the diams of pipes for supplying cities, it is necessary to bear in mind, that by far the greater portion of the 24 hours' yield is actually drawn from them during only 8 to 12 hours of daylight, and therefore the capacity of the pipes must be sufficient to furnish the daily supply in much less than 24 hours. Again, during the hot summer months, much more water is used than during the winter ones, and this consideration necessitates a still larger diam.

Art. 2. Systems of street pipes for supplying cities. The writer knows of no practical rules for proportioning the diams for such systems. The various complications involved, render a purely scientific investigation of little or no service. With much hesitation, he ventures the following purely empirical rules of his own, based on such limited observations as have casually fallen under his notice

RULE 1. *When at no point in a system of city pipes, is the head, or vert dist below the surface of the reservoir, compared with the hor dist from the reservoir, less than at the rate of 50 ft per mile, then the population in the last column of the following Table A, may be abundantly supplied, for all city purposes, by either one pipe of the inner diam or bore in the 1st col, or by 2, 3, &c, pipes of the diams in the other cols* These diams are given to the nearest safe ⅛ inch. The supply is assumed to be about 60 gallons per day to each inhabitant.

TABLE A. (Original.)

NUMBER OF PIPES. 1	2	3	4	6	8	12	24	Population
Diam. Ins.	Diam. Ins.	Diam Ins.	Diam Ins.	Diam. Ins.	Diam Ins.	Diam. Ins.	Diam. Ins.	
6	4⅜	3⅝	3⅓	3	2⅞	2⅝	1⅞	1647
8	6⅛	5¼	4⅝	4	3½	3⅛	2⅝	3465
10	7⅝	6½	5⅜	5	4⅞	3⅜	3	5308
12	9⅛	7¾	7	5⅝	5¼	4⅓	3½	9324
14	10⅝	9⅛	8⅝	7	6⅛	5⅝	4⅛	13706
16	12⅛	10⅜	9¼	7⅜	6⅞	6	4⅝	19141
18	13¾	11⅝	10⅓	8⅜	7⅜	6¾	5⅛	25677
20	15¼	13	11⅝	9⅜	8⅝	7½	5⅝	33426
22	16¾	14¼	12⅔	10⅜	9⅝	8¼	6⅛	42433
24	18⅓	15⅓	13⅜	11¾	10⅝	9	6⅝	52671
26	19⅝	16¾	15	12¾	11⅝	9¾	7⅛	64447
28	21¼	18⅛	16¼	13¾	12⅜	10⅝	8	77565
30	22⅞	19⅝	17⅝	14¾	13⅜	11½	8⅝	91580
32	24⅜	20⅝	18¼	15⅝	14	11⅞	9	108160
34	25⅞	23	19⅝	16¾	15	12⅝	9⅝	125840
36	27⅜	23¼	20⅞	17¾	15¾	13⅛	10⅜	144480
40	30⅛	25⅞	23⅓	19⅝	17⅝	15	11⅓	188320
44	33⅛	28⅔	25⅝	21⅝	19⅝	16⅓	12⅝	239600
48	36⅓	31	27⅝	23⅜	21⅛	18	13⅝	297600
54	41	34⅞	31⅓	26⅛	23⅜	20⅛	15⅝	391200
60	45⅝	38⅝	34⅝	29⅛	26⅝	22⅝	17⅛	511200
66	50⅛	42⅔	38⅛	32⅓	29⅛	24⅜	18⅝	650400
72	54⅝	46⅛	41⅝	35⅝	31⅝	26⅛	20⅛	800000
			[illegible]	[illegible]	[illegible]	29¼	22¾	1064000

It is well to allow in addition from ½ inch to 1 inch, or more, (depending on the character of the water,) to each diameter; for deposits and concretions.

The water, after reaching the city through one or more large main pipes from the reservoir, must be distributed through the streets by means of smaller mains branching from the larger ones. The diameters of these smaller ones also may be found by Table A. Thus, if a street, with its alleys, &c, contains about 6000 persons, (the rate of head being, as before, not less than 50 feet to a mile at any point of the system,) then we see by the table that a 10-inch pipe will answer. It would be well to lay no city street pipes of less than 6 inches diameter.

Mains which cross each other should be connected at some of their intersections, to allow the water a more free circulation throughout the entire system; so that if the supply at any point is temporarily cut off from one direction by closing the valves for repairs, or is diminished by excessive demand, it may be maintained by the flow from other directions.

Avoid dead ends when possible, as the water in them becomes foul and unwholesome.

RULE 2. *With the same diameters, different rates of head will supply the proportionate populations in column 3 of Table B. Or, to find the diameters which at different rates of head will supply the same populations given in the last column of Table A,* multiply the diameter given in Table A, by the corresponding number in column 4 of Table B; or (approximately) do as directed in column 5.

TABLE B. (Original.)

COL. 1.	COL. 2.	COL. 3.	COL. 4.	COL. 5.
Rate of Head, in Feet per Mile.	Rate of Head, compared with that in Table A.	Proportionate Populations.	Proportionate Diam. to supply the Populations in Table A.	Remarks.
5	.1	.32	1.58	
10	.2	.45	1.37	
12½	.25	.50	1.32	Add one third
15	.3	.55	1.27	Add full one-fourth
20	.4	.64	1.20	Add one fifth
25	.5	.71	1.14	Add one seventh.
30	.6	.78	1.11	Add one ninth.
35	.7	.84	1.07	Add one fourteenth.
37½	.75	.87	1.06	Add one sixteenth.
40	.8	.90	1.05	Add one twentieth.
45	.9	.95	1.02	Add one fiftieth.
50	1.0	1.00	1.00	
75	1.5	1.23	.92	Deduct one thirteenth.
100	2.0	1.41	.88	Deduct one eighth.
125	2.5	1.59	.83	Deduct full one-sixth.
150	3.0	1.73	.80	Deduct one fifth
200	4.0	2.00	.76	Deduct nearly one fourth.
250	5.0	2.25	.73	Deduct nearly two sevenths.
300	6.0	2.46	.69	Deduct three tenths.
400	8.0	2.83	.66	Deduct full one third
500	10.0	3.18	.63	

Example. By Table A we see that with the rate of head of 50 feet per mile, a 30-inch pipe will supply a population of 91580; but with three times that rate of head, or 150 feet per mile, we see by column 3, Table B, that the same pipe will supply 1.73 times as many persons, or $91580 \times 1.73 = 158433$ persons. But if, at this greater rate of head, we still wish to supply only 91580 persons, then we find in column 4, Table B, that we may diminish the diameter of the pipe from 30, down to $30 \times .80 = 24$ inches; or, by column 5, we have $30 - 6 = 24$ inches.

Again, after the water has reached the city by the 30-inch pipe of Table A, if we wish to distribute it through the city by say eight branches or smaller mains, we see by column 8, Table A, that each of them must have at least 13⅛ inches diameter. From these eight, other smaller ones may branch off into the cross streets, alleys, &c; and in estimating the supply required for any particular street main, we must evidently add what is required also for such cross streets, &c, &c.

If certain limited parts of a city pipe system have considerably less rates of head than most of the remainder, it may become expedient to supply the former by a special separate main of larger diameter; which may start either directly

from the reservoir; or as a branch from the grand leading main which feeds the lower parts, according to circumstances.

It must be remembered, that although by increasing the diameters, an abundant supply may be obtained under a small rate of head, as well as under a great one, yet the water will not rise to as great a height in the service pipes for supplying the different stories of dwellings, &c. Even with the diameters in Table A, the water, under ordinary use, will not rise in these pipes to the full height of the surface of the reservoir; and if an unusual drawing-off is going on at the same time at many parts of the system, as in case of an extensive fire, or frequently during the hot summer months, it may not rise to even one-half of that height.

Art. 3. The following has been found very effective for preventing concretions in water pipes. Formerly in Boston, cast-iron city pipes, 4 inches diameter, became closed up in 7 years; and those of larger diameter became seriously reduced in the same time. But later, during 8 years, in which this varnish was used, no concretions formed.*

Coal-pitch varnish to be applied to pipes and castings, made for the Water Department of Philadelphia, under the following conditions:

First. Every pipe must be thoroughly dressed and made clean, free from the earth or sand which clings to the iron in the moulds; hard brushes to be used in finishing the process to remove the loose dust.

Second. Every pipe must be entirely free from rust when the varnish is applied. If the pipe cannot be dipped immediately after being cleansed, the surface must be oiled with linseed oil to preserve it until it is ready to be dipped: no pipe to be dipped after rust has set in.

Third. The coal-tar pitch is made from coal tar, distilled until the naphtha is entirely removed, and the material deodorized. It should be distilled until it has about the consistency of wax. The mixture of five or six per cent of linseed oil is recommended. Pitch which becomes hard and brittle when cold, will not answer for this use.

Fourth. Pitch of the proper quality having been obtained, it must be carefully heated in a suitable vessel to a temperature of 300 degrees Fahrenheit, and must be maintained at not less than this temperature during the time of dipping. The material will thicken and deteriorate after a number of pipes have been dipped; fresh pitch must therefore be frequently added; and occasionally the vessel must be entirely emptied of its old contents, and refilled with fresh pitch; the refuse will be hard and brittle like common pitch.

Fifth. Every pipe must attain a temperature of 300 degrees Fahrenheit, before it is removed from the vessel of hot pitch. It may then be slowly removed and laid upon skids to drip.

All pipes of 20 inches diameter and upward, will require to remain at least thirty minutes in the hot fluid, to attain this temperature; probably more in cold weather.

Sixth. The application must be made to the satisfaction of the Chief Engineer of the Water Department; and the material be subject at all times to his examination, inspection, and rejection.

Seventh. Payment for coating the pipes will only be made on such pipes as are sound and sufficient according to the specifications, and are acceptable independent of the coating.

Eighth. No pipe to be dipped until the authorized inspector has examined it as to cleaning and rust; and subjected it thoroughly to the hammer proof. It may then be dipped, after which, it will be passed to the hydraulic press to meet the required water proof.

Ninth. The proper coating will be tough and tenacious when cold on the pipes, and not brittle or with any tendency to scale off. When the coating of any pipe has not been properly applied, and does not give satisfaction, whether from defect in material, tools, or manipulations, it shall not be paid for; if it scales off or shows a tendency that way, the pipe shall be cleansed inside before it can be recoated or be receivable as an ordinary pipe.

---

* Mr. Dexter Brackett, of Boston, informs us, 1892, that while tubercles form there in uncoated pipes to a thickness of about three-quarters of an inch, rendering 4-inch pipes of little or no value for fire supply, yet no actual stoppage has been known to occur from this cause during the twenty-three years of his connection with the City Engineering Department. He states also that even their coated pipes, taken up after being in the ground for ten or fifteen years, are generally found to be pitted on their inner surfaces.

Art. 4. The pipes are laid to conform to the vertical undulations of the street surfaces. The tops of the pipes are laid not less than 3½ feet below the surface of the street; but in 3-inch pipes the water has at times been frozen at that depth.

In Philada., in 1885, there were about 784 miles of street pipes; or about 1 mile to every 1100 inhabitants. The population was about 860,000; residing in about 150,000 dwellings. **Berlin,** 1887-8; 1,400,000 inhabitants, in 20,000 houses (average 70 persons per house). Mean consumption per head, 17 U. S gallons per day; maximum, 24; minimum, 12½, all approximate. 25,000 wheel meters in use.

No galvanic action has been observed where lead pipes or brass unite with cast-iron ones. **No pipe** less than 6 inches diam should be laid in cities; and even they only for lengths of a few hundred feet. Their insufficiency is chiefly felt in case of fire. 8 ins would be a better minimum. No more leakage occurs in winter than in summer; except from the bursting of *private service-pipes* by freezing.

To compact the earth thoroughly against the pipes excludes air, and greatly impedes rust. Pipes may be corroded by the leakage of gas through the body as well as through the joints of **adjacent gas-pipes.**

WEIGHT OF CAST-IRON WATER-PIPES,

As used in Phila, and tested by hydraulic press before delivery to an internal pres of 300 lbs per sq inch. This table includes spigots, and faucets or bells. The pipes are required to be made of remelted strong tough gray pig iron. such as may be readily drilled and chipped; and all of more than 3 ins diam to be cast vertically, with the bell end down. Deviations of 5 per cent above or below the theoretical weights, are allowed for irregularities in casting, which it seems impossible to avoid.

The pipes are in lengths from 3 to 3½ ins longer than 12 ft; so that when laid they measure 12 ft from the mouth, *f*, Fig 38, of one bell to that of the next.

Diam.	Thickness.	Wt per length.	Diam.	Thickness.	Wt per length.	Diam.	Thickness.	Wt per length.

12	$\frac{9}{16}$	899	30	1	3964	48	1½	9378

The following sizes **of lap-welded wrought-iron water-pipe** are made by the National Tube Works Co, McKeesport, Pa., and fitted with their **"Converse patent lock-joint."** One end of each length of pipe has the lock-joint permanently attached (leaded) to it at the works before shipping. The "weights per foot" include these joints. The weight of "lead per joint" given is that required to be poured in *laying* the pipe, or that for one side only of the joint.

Lead per joint, lbs	⅝	$1\frac{9}{16}$	2⅛	3¼	$3\frac{9}{16}$	5¾	6	8¾	16
Average **car load:**									
Number of lengths	800	380	275	145	126	128	80	56	49
" " feet	11500	5000	4500	2600	2000	2000	1200	800	630

The pipes are tested for a bursting pressure of 500 lbs per square inch, or higher if desired. They are furnished either coated with asphaltum, or "**kalameined;**" or, if desired, first kalameined and then coated with asphaltum. Kalameining consists in "incorporating upon and into the body of the iron a non-corrosive metal alloy, largely composed of tin." The surface thus formed is not cracked by blows, or by bending the pipe, either hot or cold.

The joint, or coupling, is of cast-iron, and has internal recesses which receive and hold lugs on the outside of each length of pipe, near each of its ends. The joint is then poured with lead in the usual way (see page 660), either with clay collars, or with a special pouring clamp furnished by the Co. This clamp resembles the "jointer," Figs 39 &c, except that it is in two rigid semi-circular pieces, connected together by a hinge-joint, and furnished with handles like those of a lemon-squeezer, and has a hole in one side for pouring The coupling forms a flush inner surface with the pipe at the joint, thus avoiding much of the resistance of cast-iron pipes to flow. For cases where it may be necessary to make frequent changes, the couplings are made in two pieces, which are bolted together by flanges.

Wrought-iron, for pipes, has the great **advantages** over cast-iron of lightness, toughness, and pliability. The lightness of wrought-iron pipes renders them easier to handle, and cheaper *per foot* notwithstanding that their cost *per ton* is about 25 per cent greater. They are not liable to breakage in transportation or from rough handling, and they may be bent through angles up to about 25°. They therefore require no special bend castings for such angles. The National Co supply bending machines, to be worked by two men. One machine can, by changing the dies, be used in bending all sizes of pipe. The pipes are in lengths of from 15 to 18 feet, instead of 12 feet, as in the case of cast-iron, so that **fewer joints are required per mile.**

The Co furnish special "service clamps" and tapping machines for **attaching service pipes to mains.** This may be done (as in the case of the Payn machine, while the main is under pressure. The service clamp is a cast iron saddle, which, before the main is tapped, is attached to it by means of a U bolt, and which remains permanently so attached after the tapping. A sheet-lead gasket is placed between clamp and main. The clamp has a tapped cylindrical opening through it, into which the corporation stop is screwed before the pipe is tapped. The drill of the tapping machine passes through the stop, and through the cylindrical opening in the clamp, and drills through the lead gasket and through the side of the main.

The Co furnish also pipe-cutting machines, and special castings (reducers, crosses, &c, &c) fitted with the Converse joint.

Art. 5. Wrought-iron pipes corrode much more rapidly than cast.

A gutta-percha pipe, ¼ inch thick, and ¾ inch bore, has sustained safely an internal pres of more than 250 lbs per sq inch; equal to nearly 600 feet head. It merely swelled slightly at 337 lbs In 1851 a tube of that material, 2½ ins bore, about ½ inch thick, and 1350 ft long, was sunk in the East River, New York, to carry the Croton water to Blackwell's Island. It was held down by weights It proved unsatisfactory owing to abrasion caused by tidal currents, and injury from the anchors of dragging vessels. A wrapping of canvas, confined by spun yarn was useful in preventing the former, but not the latter. This pipe was replaced in 1870 by wrought-iron pipes.

Ball's patent iron and cement pipe, is made by The Patent Water and Gas Pipe Co, of Jersey City, N J It is formed of riveted sheet-iron, and each length is dipped into, and coated with, a hot mixture of coal tar and asphalt. The lining of hydraulic cement is then applied This ranges, in thickness, from ⅛ inch for 12-inch pipes to 1 inch for 20-inch pipe. This pipe is made up to diams of 36 ins. It is laid in a bed of cement mortar, and completely covered with the same. Suitable means are provided for making all the attachments, &c, required in city pipes for water and gas. More than 1300 miles of it are in use in various towns some of it for 35 years; and it appears to give general satisfaction. Tubercles do not form in these pipes, as they are apt to do in cast-iron ones. There is every reason to suppose that they are durable. The trenches being dug, the Jersey City Co furnish pipes and lay them (including the cement).

A Wyckoff & Son, Elmira, N. Y., make **wooden water pipes.** For pressures of 15 to 20 lbs per sq inch, they furnish either plain pipes, 3½ to 7 ins square externally and from 1½ to 4 ins internal diam; or round pipes, 1 inch to 16 ins bore, coated externally with asphaltum cement. At their ends, both the square and the round pipes are banded with iron. For pressures from 40 to 160 lbs per sq inch, the round wooden pipes, before being coated with cement, are spirally wrapped, by steam power, with hoop iron, which is first passed through a preparation of coal tar. The iron is wound so tightly as to be imbedded in the pipe, leaving its outer surface flush with that of the wood. The ends of each length of pipe receive extra banding. The asphaltum cement coating is then applied. These pipes have been extensively and successfully used for both water and gas. Suitable arrangements are provided for joints and connections.

Water pipes of bored oak and pine logs, laid in Philadelphia in 1800-1820, are usually found quite sound, and still fit for use, except where outer sap wood is decayed When this is removed, many of these old pipes have been relaid in factories, &c. Clay *well packed* around wooden pipes, excludes the contact of air, and thus contributes greatly to their durability. Loose porous soils, such as gravel, &c, on the contrary, are unfavorable.

Pipes made of bituminized paper, prepared under great pressure, have been used for both water and gas. They are much less liable to break than cast-iron, and do not weigh or cost more than about half as much. Pipes of 5 ins bore and ½ inch thick, have resisted pressures of 220 lbs per sq inch; equal to a water head of 507 ft. British patent No. 2137, Sep 23, 1858, to A F Jaloureau, of Paris.

Costs of water pipe and laying. The following figures are deduced from a table kindly furnished by Mr. Allen J. Fuller, General Superintendent, Bureau of Water, Philadelphia. They represent average conditions for straight pipe, laid in earth, in that city. The cost, in any given case, may differ materially from these figures, according to circumstances.

"Laying" includes all handling of materials, after their delivery on the ground, for laying them in the trench, making joints, calking, etc. Calkers receive $2.50, lead men $2.00, and laborers $1.75 per day of 8 hours.

The costs of materials are taken as follows: Pipe castings, 1 2 cts; lead, 5 cts.; gasket, 3½ cts.; coke, 0 27 cts., per pound; blocking, 1.7 cts. per ft. B. M.

Add for stops, branches, fire hydrants, special castings, repaving, damages, foremen's wages, cost of tools, etc. For rough estimates, to cover fixtures, rock excavation, additional depth required for trench, wear and tear of tools, and ordinary repaving, but not including damages, asphalt repaving, or trestling, the costs in the table may be increased as follows:

Diameter of pipe	4	6	8	10	12	16 to 48 inches.
Add	80	70	65	60	50	40 per cent.

Art. 6. Cast-Iron Pipe Joints. Philadelphia standard. The clear distance, *d*, between the spigot and the faucet, is nearly uniform for all sizes of pipe, varying only from $\frac{5}{16}$ inch for 4-inch pipe, to $\frac{7}{16}$ inch for 30-inch pipe. The depth, *m n*, of the faucet varies from 3 ins in 4-inch pipe, to 4 ins in 30-inch pipe.

The small beads at *s* and *m*, *s'* and *m'* on the spigot end of the pipe, project about ¼ inch; and prevent the calking material from entering the pipe. The calking consists of about 1 to 2 ins in depth of well-rammed, untarred gasket, or rope yarn; above which is poured melted lead, confined from spreading by means of clay plastered around the joint. The lead is afterwards compacted by a calking hammer

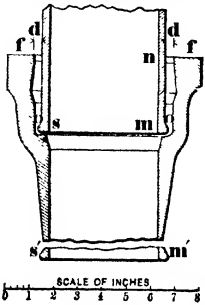

Fig 38

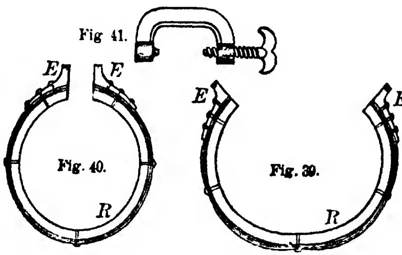
The lead is poured through a hole left in the clay on the upper side of the pipe. In large pipes, two additional holes are left in the clay, one at each side of the pipe, and lead is first poured into the side holes by two men at once, one man pouring into each side hole until the oint is half full. The side holes are then stopped, and, after the lead already poured has hardened, the two men finish the pouring by means of the top hole. This course is necessary, because the great weight of melted lead in the entire large joint would press away the clay at the lower side of the joint, and thus escape.

The moisture in the clay is liable to freeze in cold weather, and to render it too hard to be used. It is also liable, at all times, as is also any dampness in the pipe to be converted into steam by the heat of the melted lead. The steam sometimes breaks out, or "blows" through the clay, allowing the lead to escape.

Art. 7. The Watkins patent "**Pipe Jointer**" avoids these difficulties by dispensing with the ring of clay. It consists of a ring R, Figs 39 and 40, of square



cross-section, and made of packing composed of alternate layers of hemp cloth and India rubber. This ring is encircled by one or more thin strips of spring steel, which are riveted to it at intervals, as shown. E E are iron-elbows riveted outside of the steel bands. After the gasket has been rammed into its place, the ring is placed around the spigot near the faucet, in the position shown in Fig 40, and is held loosely by the clamp, Fig 41, one point of which enters a small pit in each of the elbows, E E. The ring is then, by means of a hammer, driven close up against the end, *f*, of the faucet, Fig 38; the screw of the clamp is tightened somewhat, so as to bring the ring close to the spigot; a small dam of clay is placed in front of the aperture between the two elbows, E E; and the joint is ready for pouring. After the lead has hardened, the "jointer" is removed, and is ready for use at another joint. Upon its removal the lead is found smooth, requiring no chipping. One can be used for several hundred joints. They dispense with the services of the men who prepare the clay collars, and supply them to the pourers. Thos. Watkins. Johnstown, Pa.

Art. 8. As a further preventive against the **escape of any of the gasket into the pipe,** a ring of lead pipe is sometimes placed in the joint before the gasket is inserted. This lead pipe is of such diameter that it can just be pushed through the space, *d*, Fig 38, between the spigot and the faucet; and of such length as just to encircle the water-pipe. It is driven as closely as possible into the narrow annular space at *o o*, Fig 38. The gasket is then rammed in, and the lead poured, as usual.

Art. 9. In John F. Ward's flexible joint, Fig. 42, for cast-iron pipes laid across the irregular beds of streams, a portion, *a o*, of the inside of the bell B is accurately turned to form the middle zone of a sphere, with center at C, and the narrow surface *m m*, on the outside of the spigot S, is turned to form a segment of a sphere accurately fitting the former. The lead is poured while the two adjacent lengths of pipe, resting on suitable vessels or floats, are in a straight line, or nearly so. The lead occupies the space *m n*, shown black, and is held in place on the spigot by the depression *d d*. As fast as the joints are thus filled, the floats are moved forward, and the pipes, if small, are passed into shallow water without further care. Suitable apparatus is used for lowering large pipes into deep water without undue strain on the joints. The joint permits a deflection of 15°, as shown; but further deflection, which would be liable to split the bell, is prevented by the stops at *o o* on the bell and *v v* on the spigot. In some cases preliminary dredging may be expedient, to diminish abrupt irregularities of the bottom. Over thirty lines of pipe furnished with this joint have been successfully laid, of diameters up to 3 feet.

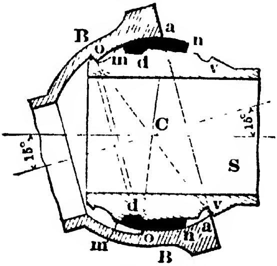


Fig. 42.

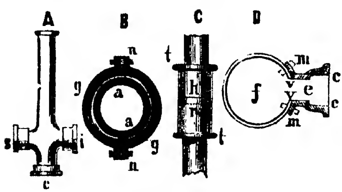
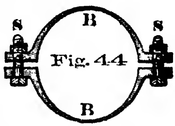
Art. 10. In Figs 43, A is **a double branch;** which is a pipe having, in addition to the faucet, *c*, at one end, two others, *s* and *i*, to which pipes leading in opposite directions (as at cross-streets) may be attached. If either *s* or *i* be omitted, the pipe is a **single branch.** The pipe is stronger when these extra faucets are near its end, than if they were at its middle. In a long line of pipes, for the sake of expedition, different gangs of men are frequently laying detached portions some distance apart; and when two ends of different portions are brought near enough together to be united, as *h* and *r*, Fig C, their junction cannot be effected by the usual spigot-and-faucet joint. In this case a cast-iron **sleeve,** *t t*, is used, which is first slid upon one of the pieces of pipe; and (after the other piece also is laid) is slid back into the position in the fig. so as to cover the joint. Sleeves are usually about a foot long; as thick as the pipe; and their diam is sufficient to allow the usual joint of gasket and lead. There is of course such a joint at each end of the sleeve.



Figs. 43

Art. 11. When a crack occurs in a pipe, *a a*, Fig B, already in use, it is repaired by means of a cast-iron sleeve, *g g*, made in two parts, bolted together by means of flanges as at *n n*. In other respects it is like the preceding sleeve. The intermediate white ring is the lead joint. If the crack is too long, or otherwise too bad to be remedied by a sleeve, the pipe is broken to pieces; and the lead joints at its ends melted out, so as to allow of its removal. Then, since an entire new pipe cannot now be inserted, owing to the overlapping of the spigot-and-faucet ends, two short pieces must be substituted for it. One end of each of these is lead-jointed to the pipes already laid; while the other two ends, which will probably be a few inches apart, are covered by a sleeve, *t t*, Fig. C.

Cracks may at times be temporarily repaired in an emergency, by a wrapping of folds of canvas thoroughly saturated with white-lead paint; and tightly confined to the pipe by a spiral banding of thin hoop-iron or wire. Or, by an iron band, made in two parts, B B, Fig 44, and clamped together by screw-bolts, S S. Such bands are useful, also, for strengthening pipes that are considered to be in danger of bursting.



Art. 12. To attach a pipe, *e*, Fig 43, to one, *f*, already in use, but in which no provision has been made for such attachment, a piece may be cut out of *f*, as at *v v*, and a casting, *e*, furnished with flanges, *m m*, bolted over the opening, by screw-bolts passing through female screws tapped in the thickness of the pipe. If the new pipe is so large that the opening, *v v*, if circular, would be inconveniently wide, it may be made *oval*, with the longest diameter in the direction of the *length* of the pipe, *f*. In that case the casting *e* will be oval at its flanges; and circular at *c c*.

Art. 13. Air valves. Air is apt to collect gradually at the high points of vertical curves along the supply pipes; and, unless removed, obstructs the flow. This may be prevented by an air valve, Fig 44A. This consists of a cast-

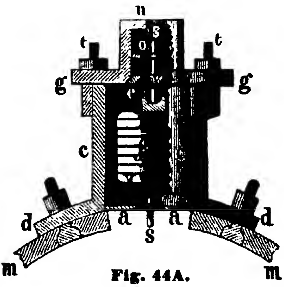


Fig. 44A.

iron box, *c c d d*, confined to the main pipe *m m*, by screw-bolts passing through its flange *d d*. It has a cover *g n g*, confined to it by screws *t t*; and at the top of which is an opening *n*, for the escape of air from within. In this box is a float *f*, which may be a close tin or copper vessel, or of layers of cork, as supposed in the fig; or &c. This float has a spindle or stem *s s*, fast to it; which passes through openings in the bridge-bars *a a*, and *o*; thereby allowing the float to rise and fall freely, but preventing it from moving sideways. When the pipe *m m* is empty, the float is down; its base *y* resting on the cross-bar *a a*. The stem *s s* has fixed to it a valve *v*, which rises and falls with it and the float. Suppose the pipe *m m* to be empty, and consequently the float and the valve *v* down. Then, if water be admitted into the pipe, it will rise and fill also the box as far up as *e*; and in doing so will lift the float *f*, and the valve *v*, to the position in the fig; thus preventing egress to the outer air by closing the opening at *v*. Now, air carried along by the water, will, on account of its lightness, ascend to the highest points it meets with.

Hence, when such air arrives under the opening *a a*, it will rise through it, and ascend to *e*; the closed valve preventing it from going farther. Thus successive portions of air ascend, and in time accumulate to such an extent as gradually to force much of the water downward out of the box. When this takes place, the float, which is held up only by the water, of course descends also; and in doing so, pulls down with it the valve *v*. The accumulated air then instantly escapes through the openings at *v* and *n*, into the atmosphere; and the water in the pipe *m m*, immediately ascends again into the box, carrying with it the float; and thus again closing the valve *v*. The valve, and the valve-seat *e*, are faced with brass, to avoid rust, and consequent bad fit. The whole is protected by an iron or wooden cover, reaching to the level of the street.

Air valves are no longer used in city pipes; their place being supplied by the fireplugs at average distances of about 150 yards apart. These, being placed as much as possible at the summits of undulations in the lines of pipes, for convenience of washing the streets, and being frequently opened for that purpose, permit also the escape of accumulated air.

The escape of compressed air through an air valve, or other opening, has been known to produce bursting of the main pipes; for the escape is instantaneous, and permits the columns of water in the pipes on both sides of the valve, to rush together with great forces, which arrest each other, and react against the pipes.

Air-Vessels. Motion is imparted to the water in a line of pipes, by the *forward* stroke of the piston of a single-acting pump; but during the *backward* stroke, this motion is stopped; and the water in the pipes comes to rest. Therefore, at the next forward stroke, all the water has to be again set in motion; and the force that must be exerted by the pump to do this is much greater than would be required if the motion previously imparted had been maintained during the time of the backstroke. The addition of an air-vessel secures this maintenance of motion, and thus effects a great saving of power; besides diminishing the danger of bursting the pipes at each forward stroke. It is merely a tall and strong air-tight iron box, usually cylindrical, strongly bolted on top of the pipes just beyond the pump, and communicating freely with them through an opening in its base. It is full of air. The forward stroke of the piston then forces water not only along the pipes, but also into the lower part of the air-vessel through the opening in its base; thus compressing its contained air. But during the backstroke, this compressed air, being relieved from the pressure of the pump, expands; and in so doing presses upon the water in the pipes, and thus keeps it in motion until the next forward stroke; and so on. An air-vessel also acts as an *air-cushion;* permitting the piston to apply its force to the water in the pipes gradually: thus preserving both the pipes and the pump from violent shocks. The air in the vessel, however, becomes by degrees absorbed and taken away by the water; and its action as a regulator then ceases. To prevent this, fresh air must be forced into the vessel from time to time by a condenser, or forcing air-pump. A *double-acting* pump does not *so much* need an air-vessel. There is no particular rule for the size or capacity of air-vessels. In practice it appears to vary from about 5 to 50 times that of the pump; with a height equal to two or more times the diameter. A stand-pipe (see below) is sometimes used instead of an air-vessel.

A stand-pipe is sometimes used for the same purpose as an air-vessel (see above). It is a tall pipe, open to the air at top; and communicating freely at its foot with the water-pipe, in the same manner as in an air-vessel. Its top must be somewhat higher than that to which the pump has to force the water through the system of pipes; otherwise the water would be wasted by flowing over its top. The area of its transverse section should be *at least* equal to that of the pipe or pipes which conduct the water *from* it; but it is at times better to have it much larger, as a stand-pipe may then answer, especially in a small town, *as a reservoir*, if the pumping should cease for a few hours. A stand-pipe should be cylindrical, not conical; for if thick ice should form on top of the water in a conical one, a sudden forcing of it upward by the pump might strain the stand-pipe seriously. The stand-pipes connected with the Philadelphia Water-Works are from 125 to 170 feet high; 5 feet diameter; and made of riveted boiler-iron about ⅜ inch thick near the base, and about ¼ inch near the top. They have no protection from the weather; nor are they braced in any manner; but retain their positions by their own inherent strength, although exposed at times to violent winds.

Art. 14. The service-pipes for supplying single dwellings, are of lead; and of ½ to ⅝ inch bore. They are connected with the street mains, n n, Fig 45, by a **brass ferrule,** *f*, here shown at ⅙ real size. The dotted lines show its ½ inch bore. The tapering ferrule is merely hard driven into a cylindrical hole reamed out of the main, as at *s*. The lead pipe, *o*, is attached to the other end of the ferrule; overlapping it about 1½ ins; and the joint soldered, *t*. The extra thickness near *f*, is for giving proper shape and strength for hammering the ferrule into the main. The pipe and solder are shown in section. Besides the stopcocks attached to each service-pipe, and to its branches through the house, there is an underground one by which the city authorities can stop off the water in case of delinquency in payment of dues; and another by which the plumber can stop it off when so required during indoor repairs. **Galvanized iron tubes** are being much used for service-pipes, especially for hot water; being less subject to contraction and expansion, which produce leaks

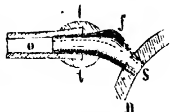

Fig 45.

Art. 15. The so-called **"corporation stops"** or "corporation cocks" are inserted into the pipe by a special machine, Fig 46. Their great advantage over the ferrule, Fig 45, is that **they can be inserted into a pipe when the latter is full of water under pressure.** Besides, inasmuch as they are *screwed* into the pipe, they are in no danger of being forced out of it by any pressure within it. As their name implies, they are furnished with a stop valve, which is kept closed while the valve is being inserted into the pipe, and is then opened, and generally remains open permanently.

Pipe-tapping machines, for drilling and tapping the pipe, and for attaching these stops, are made in a variety of forms. Fig 46 shows one made by **Walter S. Payne & Co.,** Fostoria, Ohio. Each of these machines is furnished with a number of malleable cast-iron saddles, which fit the various diams of pipe with which it is to be used. The saddle is not shown in the fig. It is fastened to the pipe by a chain slung around the latter. The chain is tightened by a bolt and nut at each end.

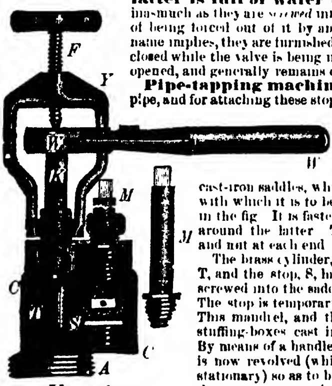

Fig. 46.

The brass cylinder, C C (into which a tap-and-drill, T, and the stop, S, have first been inserted), is then screwed into the saddle by means of the thread at A. The stop is temporarily screwed on to a mandrel, M. This mandrel, and the drill-shank, K, pass through stuffing-boxes cast in one with the head of the cyl. By means of a handle, not shown in the fig, this head is now revolved (while the body of the cyl remains stationary) so as to bring the drill, T, and stop, S into the respective positions shown in the fig. When the cyl head comes to the proper position, it is stopped by a lug inside of the cyl. The drill is then immediately over the center of a large circular opening in the base of the cyl, C C, and over a similar opening, through the saddle, to the surface of the pipe to be tapped. It is then pushed down until it touches said pipe. The ratchet-wrench, W W, is then set on the square head of the drill-shank, K; the feeder-yoke, Y, with feed screw, F, is put in position as shown; and the pipe is drilled and tapped by working the wrench; whereupon the water in the pipe, if under pressure, rushes out through the hole thus made, and fills the cylinder.

By reversing the position of the switch on the ratchet in the wrench, W, and by working the latter, the tap is now withdrawn from the hole, but remains in the cyl. The cyl head is now revolved so as to reverse the positions of S and T; the lug inside of the cyl stopping the head when the *stop* is immediately over the hole. By means of the ratchet-wrench, applied to the square head of the mandrel, M, the stop, S (*the valve of which must be closed*), is now screwed into the hole, but only far enough to hold securely, and thus prevent the further escape of the water from the pipe when the machine is now removed. The stop is now screwed firmly into place by means of a wrench applied to a square on the stop itself. When the pres in the pipe exceeds about 200 lbs per sq inch, the feeding apparatus, as used with the *drill* (see fig), may be also used in aiding the insertion of the stop.

The mandrel, M, is made in two lengths (one of which screws into the other) in order that the upper part may be out of the way of the wrench-handle while drilling. It has three or more diff threads at its foot, to suit diff sizes of stop. Stops made to suit the machine, are furnished as wanted.

The machine can work in any direction radial to the pipe, and can therefore be used for tapping a pipe in any part of its circumference.

After the stop is inserted, the service-pipe is attached to its outer end by a coupling nut passing over the thread there shown.

The machines are guaranteed to tap under a pressure of 600 lbs per square inch.

Art. 15 a. The pneumatic dome Figs 46 *a* and 46 *b*, invented by Mr. N. Monroe Hopkins, of Washington, D. C., is designed to prevent the bursting of water-pipes in freezing weather.

In unprotected pipes, the water, in freezing, is unable to expand longitudinally, and therefore frequently bursts the pipe in expanding laterally. The domes, being placed in the pipe, as shown, at intervals of about 12 feet, where freezing is to be apprehended, permit the longitudinal expansion, which pushes the ice in both directions toward each dome, where it compresses the air-cushion there provided. In the horizontal dome, Fig. 46 *a*, the double inclined planes, cast in its lower side at *c* compel the two horizontal columns of ice to rise into the dome, instead of merely abutting endwise against each other.

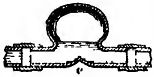

FIG. 46 *a*.

FIG 46 *b*.

In order to insure that the domes in a system (such as those for a house or mill or on a bridge) shall not be deprived of their air by the flow of the water in the pipes below them, an inspirator is placed in the pipe at the entrance to the system. The inspirator consists essentially of a constriction in the pipe, which increases the velocity of flow at that point, and thus causes an indraft of air through a valve provided for the purpose (see Venturi meter, page 532). The air, thus introduced, is carried along the pipe in bubbles between the surface of the water and the top of the pipe and is entrapped by the domes When, by closing faucets, etc, the flow in the pipe is checked, the increase of pressure closes the valve

Severe tests of both large and small pipes (4-inch and 3/4-inch), protected by these domes, have shown them to be always effective in preventing rupture.

Art. 16. Stop-valves, or **gates,** opening vertically in grooves, are placed across the street pipes at intervals of from 100 to 300 yds. Their use is to shut off the water from any section during repairs; the water of such sections being allowed to run to waste, and to soak into the ground.

The details are much varied by diff makers.

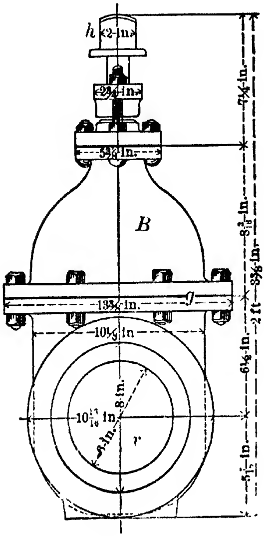

Fig. 47.

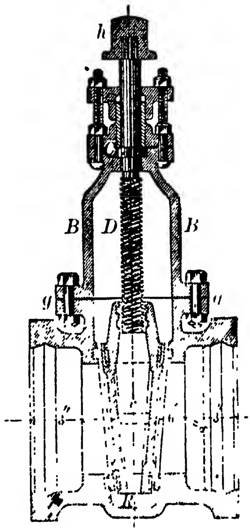

Fig. 48.

Figs 47 and 48 show such a gate. The valve, *v*, is cast in one piece. When down, as in the figs, it closes the pipe. It opens vert by means of a screw, D, the valve rising into the cast-iron case or box, B B, and leaving, when all the way up, an opening of the full diam of the pipe. The screw is turned by a wrench fitting on its square head, *h*. The screw, D, itself, is prevented from moving vert by the collar, C.

The two principal castings which compose the box or cover are bolted together by means of flanges, *g*. The joint faces of the castings are carefully smoothed; and a thin strip of lead is inserted between them, as a precaution against leaks. The recess, R, admits small particles of foreign matter which might otherwise prevent the gate from closing perfectly. The valve seats are faced with Babbitt metal. At the top of the cover, the screw stem passes through a stuffing-box, which prevents leaking at that point.

Bell-end Water-gates.

Bore. ins.	Wt. lbs.	Bore. ins.	Wt. lbs.	Bore. ins.	Wt. lbs.	Bore. ins.	Wt. lbs.
2	32	6	195	12	600	20	1706
3	55	7	245	14	843	24	2750
4	116	8	290	16	1080	30	6400
5	135	10	439	18	1475	36	8300

Art. 17. Fig 49 shows an arrangement **with outside screw** for raising and lowering the valve. Here the screw, D. does not revolve, but is attached to the valve, and rises and falls with it, being raised or lowered by turning the wheel, W, at the center of which is a nut through which the screw passes. The nut is fixed in the wheel, and is so confined that it, and the wheel, cannot move vertically.

Art. 18. A four-way stop, or **four-way valve,** Figs 50 and 51, is placed at the intersection of two mains; the four ends of which are attached, respectively, to the four openings, M M M M. At the bottom is an additional opening, connecting, by means of an elbow, H, with pipes running to a fire-hydrant at the street curb. See Arts 20 and 21. Two or more of such bottom openings may be made, if desired, for the supply of as many fire-hydrants. All of the openings are opened or closed at one time by raising or lowering the valve or plug, P, by means of a wrench or key applied to the square head, S, of the screw stem. As in Figs 47 and 48, the screw turns, but is prevented from rising and falling, and the plug moves up and down on the screw.

Inasmuch as all sediment escapes into the bottom opening which leads to the fire-hydrant, the valve is not liable to clogging through this cause. The fire-hydrant, being fed from both of the mains, obtains a fuller supply than would be possible if it were fed, as usual, through only one main.

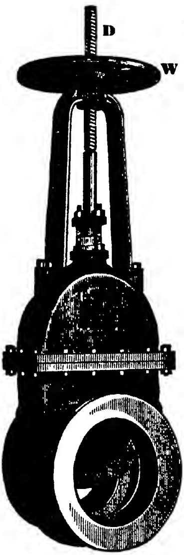

Fig. 49

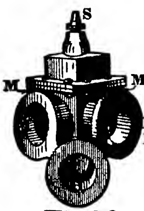

Fig. 50

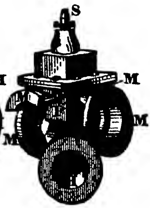

Fig. 51

Art. 19. Whatever the style of the gate may be, it is, when attached to the pipe, **protected by a surrounding box,** generally of plank or cast-iron, with four sides, which taper so that the box is of smaller hor section at top than at bottom. It is open at bottom, but has a movable iron top, level with the street. This top is taken off when the valve is to be opened or closed, or inspected. Two of the opposite sides of the box of course have openings for the passage of the pipes to or from the valve.

The gates, especially of large mains, must be closed very slowly. Otherwise, the too sudden arresting of the momentum of the flowing water would be apt to break either them or the covers; or burst the pipes. As a precaution against this, the covers for very large valves are cast with outside strengthening ribs.

No self-acting air-valves (Fig 44 A) are now placed at street summits, to allow confined air to escape. The fire-plugs answer instead. The rad for hor bends in mains is if possible not less than about 12 times their diams, they are made as large as the widths of the streets will admit: usually about 50 ft. **Fire-plugs,** Figs 52, &c are placed as much as possible at summits, so as to serve also for washing the streets: and for the escape of accumulated air. They average about 8 in number to each mile of pipe; or 1 to each block of buildings.

Fire Hydrants.

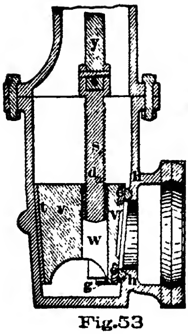

Fig.53

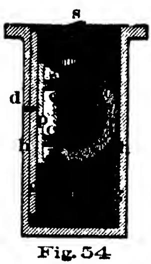

Fig. 54

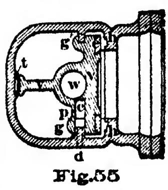

Fig.55

Art. 20. Fig 52 represents a common street **fire-plug, or fire-hydrant.**

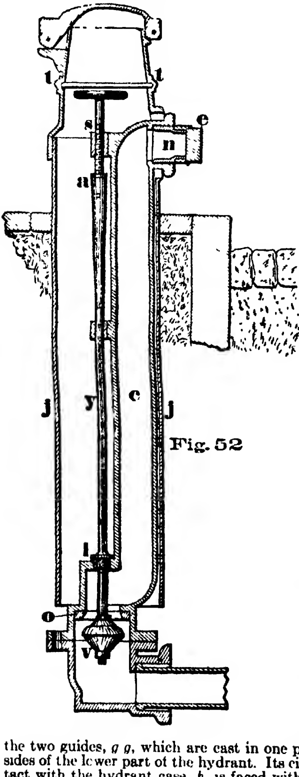

Fig. 52

The valve, *v*, is of layers of well-hammered sole-leather; and, when closed, shuts against a brass ring seat, *o*, which is confined to its place by a lead joint. The valve is opened by working down the screw, *s*, which, by means of a swivel joint at *a*, can revolve without turning the valve-rod, *y*. When the valve, *v*, is closed, after the plug has been in use, the chamber, *c*, is full of water, which, if allowed to remain, would be in danger of freezing, and of bursting the plug. But, in closing the valve, we raise the flange, *l*, on the rod, and thus allow the water to escape through the opening at *l*, whence it runs to waste into the ground, through the open lower end of the **frost-jacket,** *j j*, which is a hollow cast-iron cylinder surrounding the working parts of the hydrant. Being free to slide vert it rises and falls when the level of the ground is disturbed by frost, and the hydrant is thus protected against injury from this cause

The top, *t*, of the hydrant case, is cast in one piece with the chamber, *c*.

The stopper, *e*, screws on over the nozzle, *n*.

Art. 21. In Figs 53, 54, 55, **the valve, v v, is a *sliding* one.** The stem, *y*, Fig 53, to which the screw, *s*, is attached, is, like that in Figs 47 and 48, prevented from moving *vert* by a collar, fast to it near its top, and confined in a circular groove. When the rod and screw are made to revolve, by means of a wrench applied to the square head of the former, the valve slides up or down on the screw, admitting the water to, or shutting it off from, the hydrant. The valve slides on the two guides, *g g*, which are cast in one piece, respectively, with the two *vert* sides of the lower part of the hydrant. Its circular face, where it comes into contact with the hydrant case, *h*, is faced with a gun-metal ring, *e e*, which bears against a similar ring, made of Babbitt metal, let into the hydrant case.

The water, left in the hydrant case after closing the valve, **escapes** through a cylindrical hole, *d*, about ⅜ inch diam, bored through the guide, *g*, and case, *h*. This hole is at such a ht as to be just above the top of the loose plate, *p*, when the valve is closed, as in Fig 53. This plate lies in a vert groove in the side of the valve-casting, and is pressed against the side of the case, *h*, by two spiral springs confined in cavities, *c c*, in the valve casting. When the valve begins to rise, the hole, *d*, is closed by the plate, *p* and remains so until the valve is again entirely closed.

Test Borings. Figs 1 and 2 show a tool **for boring into soils, clay, sand,** or **gravel,** even when quite indurated, or when frozen. It will not bore through hard rock, or through large boulders. It consists of two sheet-iron cylindrical segments S S, called "pods," having their lower or cutting edges shod with steel These edges project (as shown in Fig 1) beyond the sides of the auger, and thus make the hole larger than it, so that it cannot bind or stick. The two cutting edges are equidistant from the vert cen line of the tool, and this insures a straight and vert hole. At *a* the auger is attached to the lower end of a vert boring rod composed of a number of 1½-inch square iron bars, or 2½-inch iron tubes, about 10 to 15 ft long, jointed together at their ends by means of square socket joints. At the top of this boring-rod is a swivel-hook, by means of which the entire apparatus is hung to the end of a rope, which passes over a pulley at the top of a derrick or tripod, and down to a drum worked by a windlass and gearing. By means of this drum and rope, the auger and boring-rod (which at first consists of only one bar) are lifted, and suspended over the intended hole. The auger is then lowered, and rotated hor by two men or one horse, working at the ends of levers which grip the boring-rod a few ft above the ground. The swivel at the top of the boring-rod permits this rotation to take place without twisting the rope. The shape of the auger is such that its rotation feeds or screws it into the ground; and the man at the windlass has, during the boring, merely to keep the rope tight, so as to prevent the auger from boring too fast, and becoming clogged. In about 8 revolutions the auger fills with earth. By means of the windlass it is then raised to about 2 ft above the ground; and by unkeying and removing the band *b* the auger is opened like a pair of tongs, and the earth emptied into a wooden box which has in the meantime been placed over the hole. The box is then removed and emptied, and the boring proceeds as before. When the boring has reached a depth of about 10 ft, a second bar must be added to the top of the rod. For this purpose the rod and auger are raised a few inches; a slight frame-work of boards is placed on the ground, close to the boring-rod and surrounding it; and a flange is clasped tightly to the rod just above, and close to, the framework. The framework and flange now support the rod and auger; the swivel-hook and rope are removed, and attached to the upper end of the second bar, which is then raised, and its lower end is fastened into the socket-joint upon the top of the first one. The rope is then drawn tight; the flange removed; the auger lowered to the bottom of the hole; and the boring resumed. Additional lengths of boring-rod are attached in the same way from time to time, as required by the descent of the auger.

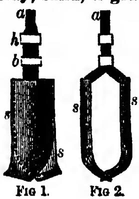

Fig 1. Fig 2.

The borers may be made from 6 to 18 inches in diameter, or larger. If desired, the boring may be made from 24 to 36 ins diam by attaching a reamer to the auger. This auger will bore to a depth of 100 ft or more at the rate of from 5 to 20 ft per hour. It removes stones as large as half the diam of the hole. In dry soils a bucketful of water is poured into the hole each time the auger is raised.

This borer may be advantageously used in boring the holes for **sand piles,** and at times, **instead of driving wooden piles,** it may be better to *plant* them (butt down if preferred) in holes bored by this auger; ramming the earth well around them afterwards. This will save adjacent buildings from the jarring and injury done by a pile driver.

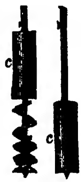
If sand, mud, or loose gravel is reached in boring with this tool, the hole is reamed out 4 ins larger, and a **tubing** of inch boards is inserted into the hole, and driven into and through the sand or gravel, which is then removed from within the tubing by means of a **sand-pump,** consisting of a hollow iron cylinder, about 5 ins diam × 30 ins long, with a valve at its foot, opening upward. The sand-pump is lowered to the bottom of the hole; covered with water to a depth of 2 to 4 ft, and churned quickly up and down 4 to 6 ins, by hand, 20 or 30 times, during which the sand fills the pump, which is then drawn up and emptied. From 10 to 20 ft in depth of sand, mud, &c, per hour can thus be taken from a 6 to 18-inch hole. This pump is also used for removing broken earth, &c, from a hole bored in compact earth by the borer first described.

The cost, with derrick, boring-rods, rope, sand-pump, &c, &c, complete, is about $175. **The auger weighs** from 150 to 200 lbs, according to size. Boring-rod 1½ ins sq, 3⅔ lbs per ft. Derrick, 150 lbs.

The sand-borer, Figs 3 and 4, like the sand-pump just described, is used inside of tubing, and for the same purpose. The hollow iron cylinder C, 10 ins diam × 30 ins long, slides vertically on the rod, but the screw is fast to the rod. While boring, the sand below and around the cyl keeps it in the position shown in

Fig 3. Six revolutions of the rod and screw fill the cyl with sand. The rod is then lifted. This first draws the screw up into the cyl, as in Fig 4; and a valve at the foot of the screw closes the bottom of the cyl, and prevents the sand from falling out when the borer is lifted from the hole. The rod is hollow, and open at top and bottom. This allows passage of the air, and thus prevents resistance from suction in withdrawing the borer. This tool is rotated and withdrawn in the same way as the earth borer first described. Cost about $30.

Steel prospecting augers, from 2 to 4 ins diam, and 2 ft long, are used for boring holes from 2½ to 6 ins diam, and to depths of 10 to 50 ft, into **clay, sand,** or **fine gravel,** of all of which they bring up samples. They are turned by wrenches, and by man or horse power. See also p 674.



Figs 3, 4

The boring tool shown in vert section by Fig 6, and in hor cross section by Fig 5, is very useful **for boring shallow holes by hand through surface soils,** clay, and gravel, and bringing up samples. The borer proper consists of a cylinder of spring steel, 3 or 4 ins diam, and 4 or 5 ins high, with sides ¼ inch thick, having a vert slit (see cross section) throughout its height, and beveled to a cutting edge all around its foot, as shown in the vert section. At its top it is riveted, as shown, or welded, to the inverted-v-shaped forging, which, by means of the socket at its top, is screwed to a length of gas-pipe which serves as a handle, and to which other pieces are joined by sockets as boring proceeds.

The boring is done by two men, who grasp the handle, and, holding the tool vert, drive it into the ground by repeatedly lifting it and forcibly bringing it down upon the same spot. As the tool strikes the ground, the beveled shape of its cutting edge causes it to open slightly, and when the downward pres is relieved in lifting it, it springs back and grasps the earth which has entered it. It soon fills, and the men, finding that it ceases to penetrate readily, lift it to the surface and empty it. The character of its contents from different depths, measured along the handle, is noted from time to time.

In six days of 8 hours each, three men (one resting at intervals) using one such auger between them, bored 20 holes, averaging 9½ ft each, in loam, gravel, clay, and decomposed mica schist, at a cost of 22 cts per foot. Wages of each man, $2 per day.

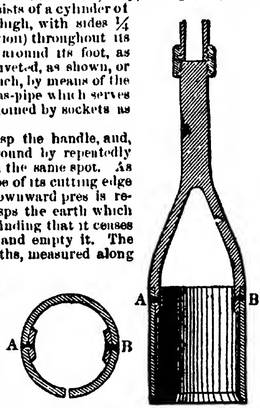


Fig 5. Fig 6.

For work in loam, clay, or non-running sand, **an effective screw-auger** can be made by any good blacksmith, by merely forming a one-inch sq bar of iron or steel into corkscrew shape about 2 ft long with 6 complete turns 6 ins in diam; its lower end sharpened to form a vertical cutting edge, which should project say .5 of an inch beyond the spiral of the screw, in order to diminish friction. It will bring up full samples. Requires a derrick, or some other simple mode of lifting, when the screw is full.

Artesian Well Drilling. Deep vert holes in earth and rock, 6 and 8 ins in diam, such as are reqd for artesian wells for water and oil, and for mining explorations, are drilled by repeatedly lifting and dropping, in the same vert line, a heavy iron bit, Fig 1, p 673, with a steel cutting-edge. The bit is partly revolved horizontally after each blow, to insure roundness of hole. The length of the cutting-edge of the bit is a little greater than the diam of the bit, and the hole is thus made sufficiently large to prevent the bit from binding in it.

The bit is the lowest one of a series of iron and steel bars, &c, screwed together at their ends, and called a **"string of tools."** The string of tools varies in length from 25 to 60 ft, according to the size and depth of the hole, and the hardness of the rock; and its diam throughout (above the cutting-edge) is an inch or two less than that of the hole. Its weight is from 800 to 4000 lbs. Its upper member is always a "rope-socket," Fig 4 (*without* a swivel), to which the lower end of the supporting rope **cable** is attached. This cable passes up out of the hole to **a hor lever,** which, by means of a horse-power or steam-engine, is kept constantly moving up and down with a see-saw motion. The string of tools, with the cutting edge of the bit at its lower end, is thus alternately lifted from 2 to 4 ft, and

let fall, from 30 to 50 times per minute, and so drills its way into the rock or earth. From 4 to 10 ft in depth of water are kept in the hole, to facilitate the drilling and the removal of debris. After water is reached, the drilling may be continued, even if the hole is full of water; but a great depth of water of course diminishes the force of the blows of the bit. A suitable arrangement must be provided for **paying out the rope** as the boring tool descends. A clamp is attached to the cable, and the man in charge, by turning the clamp, twists the rope, and thus **turns the bit horizontally** about one-fifth of a revolution after each stroke, until six or eight complete revolutions have been made in one direction. He then reverses the motion, and makes an equal number of turns, at the same rate, in the opposite direction.

After drilling a few feet, the string of tools is lifted out of the hole by means of the cable, to allow the **removal of the debris** which has accumulated in the hole. This is done by means of a **sand-pump**, which is a sheet-iron cylinder, say 4 ins diam, and 4 to 6 ft long, provided at its foot, with a valve opening upward. The pump is lowered to the bottom of the hole, and filled with the mixed water and debris by churning it up and down a number of times. Sometimes, in addition to the valve, the pump is fitted with a plunger, which is at the foot of the pump when the latter is let down to the bottom of the hole. The plunger is then drawn up into the pump, and the debris follows it. In either case, the pump, when filled, is lifted out of the hole and emptied; the string of tools is again lowered into the hole, and the drilling resumed. The debris must be removed after every 3 to 5 ft of drilling. Otherwise it would interfere too greatly with the action of the bit.

Wells are usually drilled from 6 to 8 ins diam. For diams less than 6 ins, the tools are so slender that they are liable to be broken in a deep hole.

The same apparatus is used for **drilling through the earth above the rock,** before the latter is reached. This is called "spudding." In this case the sides of the hole must be prevented from caving in. For this purpose a wrought-iron pipe of such diam as to fit the hole closely, and ¼ inch thick, is inserted into the hole, and is driven down from time to time as the drilling proceeds. The pipe is driven by means of a heavy maul of oak, or other hard wood, 14 to 18 ins square, and 10 to 16 ft long. This maul is attached, by one end, to the lower end of the same cable which, during drilling, supports the string of tools. It is thus repeatedly lifted, and dropped upon the head of the tube, which is protected by a cast-iron "driving-cap." The foot of the tube is shod with a steel cutting-edge ring, or "steel shoe." When the tube has been driven as far as it will readily go, the maul is removed from the end of the rope; the string of tools substituted; and the drilling resumed within the pipe.

The pipe is put together in lengths of from 8 to 18 ft, and the drilling and pipe-driving proceed alternately until the rock is reached, and the foot of the pipe forced into it to a depth of a few ins, or far enough to shut off quicksand or surface water.

If quicksand is encountered, the string of tools is removed, and the sand-pump is used inside of the pipe.

For reaming out, or **enlarging, holes,** or for **straightening** crooked ones, &c, special tools, such as reamers, &c, are substituted in place of the boring bit.

Special care must be taken to have **all the rubbing surfaces thoroughly lubricated.** The pulley in the mast-head, and the pinion-wheels of the horse power (if such be used) should be well oiled every two or three hours.

In very **cold or wet weather, a shed of rough boards,** or a covering of canvas, about 8 ft high, should be erected, to protect the men; and, if steam is used, 2 or 3 boards should be used as a covering for the belt, which will slip if wet.

For holes from 200 to 1000 ft deep, **portable drilling machines,*** worked by horse or steam power, are used. In these machines, the drill-rope, extending from the string of tools up out of the hole, passes over a sheave at the top of a wooden mast; down to, and around, a pulley fast to the working lever; and thence, by way of a pulley fixed at the foot of the mast, to a drum upon which it is wound. To this drum a friction and ratchet wheel is attached, for paying out the cable as the tools descend.

The mast is hinged six feet above its foot, so that its upper part may be laid hor when the machine is to be moved. When at work, it is held in position by two timber struts or braces, bolted to it near its top, and having their lower ends fastened to the "**drill-jack,**" which is a light and strong framework, 9 ft long, 8 ft wide, and 4 ft high, at the foot of the mast, containing the working lever which

* See Price-list, 3.67.

raises the rope and lets it fall, the drum on which the rope is wound, the shaft and cam which work the lever, &c. The operator stands at the foot of the mast, and by means of foot- and hand-levers within his reach, regulates all the movements of the machine. One of these governs the pawl and ratchet wheel regulating the paying out of the cable. By letting the ratchet-wheel of the drum move one notch, the bit is fed down quarter of an inch.

The operator, by moving a slide with his foot, holds the working lever down, out of reach of the cam, thus stopping the up-and-down motion of the rope and tools. By means of another lever he can now put the rope-drum in gear with the main driving-shaft, so that the rope is wound up on the drum, and the tools drawn up out of the hole. Another lever controls the separate reel on which the light rope, carrying the sand-pump, is wound. All these operations are performed by the same power (horse or steam, as the case may be), which works on without stopping; the various changes being made by merely throwing the different parts into, or out of, gear with the main driving-shaft.

Fig. 4.

One of these portable machines requires two horses or a small steam-engine, a man to attend the same, and another man to operate the machine, empty the sand-pump, change the tools, &c. It can be transported on a farm wagon over any common road. Two men can unload it, set it up, and commence drilling, in two hours; and, unless steam is preferred, the two horses used for its transportation furnish the motive power. The machine can be taken down and reloaded in the wagon in two hours.

Figs 1 to 4 show the **tools used with these machines.** For the different sizes of machine they differ chiefly in their dimensions and weights.

Fig 1 shows the **drilling bit,** which is 30 to 36 ins long, and weighs about 100 lbs. Its lower or cutting edge is 6 ins long. Its top is screwed into the foot of the "**auger-stem,**" Fig 2, which is of 3-inch round iron, 12 ft long, and weighs 350 lbs. Its use is that of a weight, giving additional force to the blows of the bit. Its top is screwed into the foot of the "**drill-jars,**" Fig 3; and to the top of these is screwed the "**rope-socket,**" Fig 4, to which the drilling cable is attached. **If the bit, or auger-stem, becomes wedged in the hole by any means,** the operator stops the churning motion of the tools, and the rope is let out about 12 ins. This permits the upper link U of the drill-jars, Fig 3, to slide down about 12 ins in the slot S in their lower link. The churning motion is then started again, and the upward jerk of the link U against the upper end of the slot loosens the tools.

Fig. 2.

These machines are made in a number of sizes, to drill holes from 200 to 1000 feet deep. The string of tools weighs from 800 to 1800 lbs; and the machine complete including tools, rope, mast, etc., but exclusive of power, from 1800 to 4500 lbs. They cost from $700 to $1500 exclusive of power. The smaller sizes may be worked by horse power. A horse power weighs about 800 lbs, and costs about $75. Steam engine, 1600 to 3600 lbs., $150 to $300.

For wells from 1000 to 3000 feet deep, a stationary machine, with a walking-beam, is used, similar to those employed in the oil regions of Pennsylvania. A square pyramidal derrick is erected, 74 feet high, 20 feet square at base, 4 feet square at top. Each of its 4 corner legs is of 2 inch × 8 inch and 2 inch × 10 inch planks, spiked together so as to form a 10 inch × 10 inch angle-piece, 2 inches thick. The legs are braced together by horizontal and diagonal timbers. The walking-beam is of timber, 26 feet long, 12 inches wide, and 26 inches deep at the middle of its length, where it is pivoted to the top of a wooden post 18 inches square and 12 feet high, called a "Samson post."

Fig. 1.

Fig. 3.

This post, at its foot, is dovetailed into the main sill of the machine, which is 18 inches wide × 24 inches deep.

The motive power is a 15-hp steam-engine, which, by means of a belt and pulley crank and pitman, working at one end of the walking-beam, gives to the latter its see-saw motion. To the other end of the beam, and immediately over the well, is suspended, by means of a hook, a "temper-screw." This last is composed of two bars of iron, about $\frac{5}{8} \times 2$ ins, 5 ft long, hung 2 ins apart, fastened together at their top ends, at which point there is an eye, which is suspended on the walking-beam hook. At the bottom of the two bars there is a sleeve-nut, and between the two bars and passing through the nut, is a screw 5 ft long, at the bottom of which there is a head, which carries a swivel, set-screw, and a pair of clamps. These grasp the cable, 2 or $2\frac{1}{4}$ ins diam, which carries at its lower end the **string of tools.** This, for a 2000-ft hole, consists of a steel bit, 3 or 4 ft long, weighing 200 to 400 lbs; an auger-stem of 4 or 5-inch round iron, from 24 to 30 ft long, and weighing from 1200 to 2100 lbs; steel-lined drill-jars 8 ft long, weighing 600 to 700 lbs; a sinker-bar of round iron of same diam as the auger-stem, 12 to 15 ft long, and weighing from 600 to 1100 lbs; and a rope-socket, $2\frac{1}{2}$ ft long, weighing 200 lbs. Total length of string of tools, 50 to 60 ft, total weight, 3000 lbs; or, for an 8-inch hole in the hardest rock, 4000 lbs. **The sinker-bar** is added to give additional wt, and thus to assist in pulling the cable down through the water, either in lowering the string of tools or in working the drill-jars. The shapes of the other tools are given by Figs 1 to 4. **Special tools** are used for recovering articles that may be accidentally dropped into the hole.

The drilling cable is wound on a drum, called a bull-wheel shaft, at the foot of, and inside of, the derrick. While drilling is going on, it passes from the bull-wheel shaft loosely over the sheave at the top of the derrick, and down to the clamps at the lower end of the temper-screw on the end of the walking-beam. As the drilling progresses, the temper-screw is turned or fed out by the man in charge, who also, by means of a clamp, twists the rope, so as to change the position of the bit after each stroke.

When the tools are to be lifted out of the hole, the cable is disengaged from the clamps on the temper-screw, and is wound upon the bull-wheel shaft, which, for this purpose, is thrown into gear with the steam-engine; the pitman being at the same time removed from the crank-pin, so that the walking-beam is at rest. As in the portable machines, the sand-pump is also raised by the same power which does the drilling.

About 10000 ft b m of rough lumber are reqd for the derrick, walking-beam, sills, &c, and about 3000 ft more for sheds over the boiler, engine, and belt

In ordinary hard limestone rock, such a **machine will drill** about $1\frac{1}{2}$ ft per hour under the most favorable circumstances. **Two men are required;** one to attend to the boiler, sharpen the bits, &c, and one to operate the machine.

In Pierce's machine for test-boring, mineral prospecting and well boring, the pipes are driven by an iron ram, like that of a pile driver, but bushed with hard wood on its lower or striking end. The ram is worked by a hand winch The pipes are in lengths of 5 to 10 feet. After each length is driven, water,* under pressure, is forced, by a hand pump, through a hollow drill rod, into the bottom of the hole, while the drill rod is churned up and down by hand. The water forces the drillings (mud, sand, gravel, etc.) to the surface. The smallest machine drives 2 to 3 inch pipes; the largest, 2 to 8 inch. The machines are in detachable parts, weighing from 10 to 65 lbs each. Four upright iron pipes, which carry the head casting and crown pulley, act as guides for the ram, their ends fitting into sockets in castings at their heads and feet. The driving rams are made in sections which are bolted together. In the smaller machines the weight of the ram may thus be made from 100 to 200 pounds, and, in the larger machines, from 100 to 2,000 pounds, as required. Borings can be made to depths of 100 to 400 feet. These machines have been extensively used in Nicaragua by the Isthmian Canal Commission. If desired, the machines can be furnished with special tools for boring in rock and for taking out solid cores (as with the diamond drill), with others for taking out dry cores in earth, and with sand-pumps and mud sockets for bringing up mud, fine sand, gravel, and detached pieces of rock and minerals.

---

*In Alaska, where the frost extends to great depths, boiling or hot water is used. This is obtained by melting ice or snow in iron tanks about 4 ft square and 2 ft deep.

MACHINE ROCK-DRILLS.

Art. 1. Machine Rock-drills bore much more rapidly than hand drills, and more economically, provided the work is so great as to justify the preliminary outfit. They drill in any direction, and can often be used in boring holes so located that they could not be bored by hand. They are worked either by steam directly; or by air, compressed by steam or water power into a tank called a "receiver," and thence led to the drills through iron pipes. The air is best for tunnels and shafts, because, after leaving the drills, it aids ventilation.

Art. 2. Such drills are of two kinds: rotating drills and **percussion drills.** In the former, the drill-rod is a long tube, revolving about its axis. The end of this tube, hardened so as to form an annular cutting-edge, is kept in contact with the rock, and, by its rotation, cuts in it a cylindrical hole, generally with a solid core in the center. The core occupies the core-barrel, Art 8. The drill-rod is fed forward, or into the hole, as the drilling proceeds. The debris is removed from the hole by a constant stream of water, which is led to the bottom of the hole through the hollow drill-rod, and which carries the debris up through the narrow space between the outside of the drill-rod and the sides of the hole.

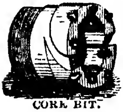
In **percussion drills,** the drill-rod is solid, and its action is that of the churn drill.

Art. 3. In the **Brandt** (European) **rotary drill,** the cutting-edge at the end of the tubular drill-rod is armed with hardened steel teeth. It is pressed against the rock under enormous hydraulic pressure, and makes but from 5 to 8 revolutions per minute.

Art. 4. The Diamond drill is the only form of rotary rock-drill extensively used in America. In it, the boring-rod consists of a number of tubes jointed rigidly together at their ends by hollow interior sleeves.

Art. 5. The boring-bit, Fig 1, is called a "core-bit." Its cutting-edge has imbedded in it a number of **diamonds** as shown. These are so arranged as to project slightly from both its inner and outer edges. Annular spaces are thus left between core and core-barrel, and between the latter and the walls of the hole These spaces permit the ingress and egress of the water used in removing the debris from the hole, and, at the same time, prevent the core from binding in the barrel, or the latter in the hole.

Fig. 1

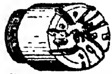


CORE BIT.

Fig. 2

CORE LIFTER.

Fig. 3



BORING HEAD.

Art. 6. Just above the "core-bit," the **"core-lifter,"** Fig 2, is screwed to the barrel. This is a tube about 8 ins long and of the same outer diam as the barrel. Inside it is slightly coned, with the base of the cone upward, and furnished with a loose split-ring, R, toothed inside, and similarly coned. While the drilling is going on, this ring encircles the core closely, and remains loose from the outer cylinder; but when the drilling is stopped, and the drill-rod begins to be raised, the ring is caught and raised by the outer cylinder: and, by reason of its beveled shape, is pressed hard against the core of rock, which is pulled apart close to its foot by the power which lifts the drill-rod.

Art. 7. This power is supplied by a **rope-drum.** fastened to the top of the frame which supports the drill and worked by the same engine which rotates the drill-rod. The rope from the drum passes up to a pulley at the top of a **derrick,** and thence down to the upper end of the drill-rod. The considerable height of the derrick enables from 40 to 60 feet of the drill-rod to be removed in one piece.

Art. 8. Above the "core-lifter" is the **"core-barrel."** This is a wrought-iron tube from 8 to 16 ft long. It is spirally grooved outside, to permit the ascent of the water and debris from the hole; and is sometimes set with diamonds on its outer surface, to prevent wear. The bit, lifter, and barrel are of uniform outer diam, a little less than the diam of the hole. The outer diam of the drill-rod varies from about $1\frac{1}{4}$ ins for 2-inch barrel to $5\frac{1}{2}$ ins for 18 inch barrel.

Art. 9. Where it is not desired to preserve the core intact, a "**boring-head,**" Fig 3, may be used instead of the "core-bit." Fig 1. This is a solid bit (except that it is perforated with holes which allow the water to pass out from the drill-rod), and is armed with diamonds, some of which project beyond its circumference.

Art. 10. The drill-rod **revolves at a speed** of from 200 to 400 revolutions per minute. **The engine,** by which it is rotated, consists usually of two cylinders, either fixed or oscillating, operated by steam or compressed air, and working at right angles to each other. By means of cranks they turn a shaft, which communicates its motion, through bevel gearing, to the drill-rod. The latter is **fed down,** as the hole progresses, either by other **bevel gearing** driven by the same engine; or by being attached to a cross-head which connects the piston rods of 2 **hydraulic cylinders,** the piston rods being parallel with the drill rod.

Art. 11. The diamond drill bores perfectly **circular holes, in straight lines and in any direction, to great depths;** from 300 to 1500 feet being not uncommon. This, with the fact that **it brings up unbroken cores,** from 8 to 16 ft long, which show the precise nature and stratification of the rock penetrated, renders it very valuable in test-boring, prospecting of mines, &c. They are also furnished of sufficient size to bore holes from 6 to 15 ins diam, for **artesian wells.** The roundness of the holes bored enables the use of casing of nearly as great diam as that of the hole; and their straightness is advantageous in case a pump has to be used.

Art. 12. In soft rock a bit may drill through 200 ft or more without resetting. On the other hand, in very hard rocks, similar drills will wear out in 10 ft or less. In 1883-4, a diamond drill by the Am'n Diamond Rock Boring Co, weighing complete about 1400 lbs. and costing about $2800, bored, in 1428 hours of actual boring, 53 holes of 2 ins diam, and aggregating 9141 lineal ft. Average length of hole 172.5 ft. **Average rate,** 6.4 lin ft per hour; greatest, 12.8. **Average total cost,** about 96 cts per lin ft. The rock was principally limestone, with some quartz and sandstone. The holes were bored at angles varying from 0° to 45° with the vertical.

As a rough average we may say that **in ordinary rocks,** as granite, limestone, and hard sandstone, these drills will bore deep holes, 2 to 3 ins diam, at **from 1 to 2 ft per hour,** and at a cost of from **$1 to $2 per ft.**

Art. 13. These drills are made of many widely **different sizes,** and with **different mountings,** depending upon the nature of the work to be done.

They are sold under restrictions as to the location and extent of the territory in which they are to be used. **The prices** depend, to a great extent, upon the nature of these restrictions. The card prices for some of the leading sizes, are as follows: Discount, see price list.

Diam of hole.	Diam of core.	Depth of hole.	Boiler H. P. required.	Card price. Drill.	Card price. Pump
Ins.	Ins.	Feet.	H. P.	$	$
$2\frac{9}{16}$	2	4000	25	4000	....
$2\frac{1}{16}$	$1\frac{1}{2}$	1500	15	2500	3400
"	"	1000	12 to 15	1900	2800
$1\frac{9}{16}$	1	600	10	1400	1900
"	"	400	hand	425	....

Art. 14. In percussion drilling machines, the drill-bar is driven forcibly against the rock by the **pressure of steam or of compressed air,** acting upon a piston, P, Fig 4, moving in a cylinder, C C, Figs 4 and 5; and makes about 300 strokes per minute. The rotation of the drill-bar is accomplished automatically, as explained in Art 27.

Art. 15. The cylinder, C C, is free to slide longitudinally in the fixed frame or shell, S S, Fig 5, to which it is attached, and which, in turn, is fixed to the tripod or other stand (see Arts 18 and 19) upon which the machine is supported.

Art. 16. The drill-rod, R, corresponding to the churn drill, is fastened, by an appropriate chuck, K, to the end of the piston-rod, O. The drilling is begun with a short drill-rod, and with the cylinder as far from the hole as the length of the shell, S, will permit. As the bit penetrates the rock, the cylinder is fed forward,* either automatically or by hand (see Art 28), as far as the length of

* By **forward,** or **downward,** we mean *toward* the hole which is being drilled. By **backward,** or **upward,** *from* the hole.

the shell permits. The drilling is then stopped, by shutting off the steam,* and the cylinder is run back, by reversing the motion of the feeding apparatus. The short drill-bar is then removed, and, if the drilling is to be continued, a longer one is substituted in its place, and the process repeated.

Art. 17. Inasmuch as the act of drilling wears the edges of the bit, thus reducing its diam somewhat, **the hole will of course be tapering,** or of slightly less diam at bottom than at top. The second bit must therefore be of slightly less diam than the first; say from $\frac{1}{16}$ to $\frac{1}{8}$ inch less; the third must be less than the second, and so on. On the other hand, in long holes, the drill-bar will seldom be in a perfectly straight line, so that the bit, instead of striking always in the same spot, will describe a circle, and thus enlarge the hole.

Art. 18. The shell, S, in which the cylinder slides, is provided with an arrangement by which it may be clamped, either to a **tripod,** as in Fig 5, or to a long **bar** or **column,** along which it may slide. The column, if hor, may rest upon two pairs of legs; or it may be braced, in any position, against the opposite sides of a narrow cut, or against the floor and ceiling of a tunnel-heading, &c, in which case one of its ends is provided with a screw which is run out so as to cause the two ends of the col to press firmly against the opposite rock walls; or rather against wooden blocks which are always placed between each end of the col and the rock. In any case, the supports of the drill are so jointed that it can bore in any direction.

Art. 19. Frequently the drill is **clamped to a short arm,** which, in turn, is clamped to the column, and projects at right angles from it. The arm may be slid lengthwise of the column, and may be revolved around it, and thus may be placed in any desired position, and there clamped. This gives the drill a greater range of motion, and enables it to bore holes over a greater space than would otherwise be possible without moving the column.

Art. 20. In tunnels, one or more drills may be mounted upon a **drill-carriage,** travelling upon a railroad track running longitudinally of the tunnel. Upon this track the carriage is moved up to the work, or run back from it when a blast is to be fired The gauge of the track may be made wide enough to admit of a second track, of narrower gauge, running underneath the drill-carriage. Upon said narrower track the cars are run which carry away the debris. Drill-carriages are less commonly used in this country than in Europe.

Art. 21. The pressure used in the cylinders of percussion drills is usually from about 60 to 70 lbs per sq inch. **In an hour, one will drill** a hole from 1 to 2 ins diam, and from 3 to 10 ft deep, depending on the character of the rock and the size of the machine at from 10 to 25 **cts per lin ft** with lab r; at $1 per day. **A bit requires sharpening** at about every 2 to 4 ft depth of hole. One blacksmith and helper can sharpen drills for 5 or 6 machines.

Art. 22. The bits are of many different shapes, varying with the nature of the work to be done. For uniform hard rock, the bit has two cutting-edges, forming a cross with equal arms at right angles to each other. For seamy rock, the arms of the cross are equal, but form two acute and two obtuse angles with each other, as in the letter X. For soft rock, the cutting-edge sometimes has the shape of the letter Z.

Art. 23. Each drill requires one man to operate it. Two or three men are required for moving the heavier sizes from place to place. One man can attend to a small air-compressor and its boiler.

Art. 24. Figs 4 and 5 represent the "**Eclipse**" percussion drill of the Ingersoll-Sergeant Drill Co. Havemeyer Building, New York Fig 5 shows the drill, mounted (as is most frequently the case) upon a tripod. Fig 4 is a longitudinal section through the cylinder, valve-chest, and piston.

Art. 25. The cylinder, C, is provided at each end with a **rubber cushion,** N, for deadening the blows of the piston, which, in all percussion drills, is liable, at times, to strike either cylinder-head. The side of each cushion nearest the piston is protected by a thin iron plate. The cushions have to be renewed from time to time.

Art. 26. The valve, V, is shaped somewhat like a spool. The bolt, B, passes loosely through its center and guides it. Steam is admitted from the boiler to the steam-chest, and occupies all of the space between the two end flanges of the valve, except *u*. It drives the valve alternately from one end of the valve-chest to the other, and back, according as one end or the other is relieved from opposing pressure by being put into communication with the exhaust, *E*, by way of the passages, D D′ and F F′. D and D′ communicate with the ends of the steam-chest through passages not shown; while F and F′ communicate, through similar passages, with the exhaust, E. The piston has an annular channel, L L′, encircling it. Whatever the position of the piston, one of the passages, D or D′, is always, by means of this channel, in communication with its corresponding passage, F or F′, leading

* To avoid repetitions, we will use the word **steam** to signify either *steam* or *compressed air* whichever happens to be used.

to the exhaust. Thus, one or the other end of the valve-chest is always in communication with the open air; and to that end the valve is driven by the pres of the steam surrounding it, admitting steam to the cyl, C, from the other end.

Art. 27. The rotation of the piston, and, with it, that of the drill-bar, is effected thus: The spirally-grooved, cylindrical steel bar, A, called a **rifle-bar,** passes through and works in, the **rifle-nut,** H, which is firmly fixed in the end of the piston, and has spiral grooves corresponding with those on the rifle-bar. Said bar is fixed, at its upper end, to the ratchet-wheel, J, the pawls of which are so arranged that, on the *down* stroke of the piston, the rifle-nut, H, acting upon the grooves on the rifle-bar, causes it, and, with it, the ratchet-wheel, to revolve about their common axis. The weight and momentum of the piston, &c, are such that it thus readily turns the ratchet-wheel without itself turning. Thus the bit is prevented from rotating while delivering its blow. But, on the *up* stroke, the tendency of the rifle-nut is to turn the rifle-bar and ratchet-wheel in the *opposite* direction; and as this is prevented by the pawls, the *rifle-bar* remains *stationary*, while the *piston, piston-rod*, and *drill* are *made to revolve* about their common axis.

Art. 28. The feed-screw, M, is collared, at its upper end, to the fixed frame, Q. It is thus prevented from moving longitudinally when revolved by means of the crank fixed to its top. Its lower end works in a nut, T, fixed to the cylinder, which last is thus moved longitudinally backward or forward as the crank is turned.

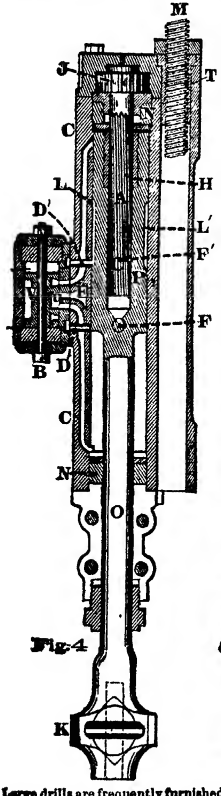


Fig. 4

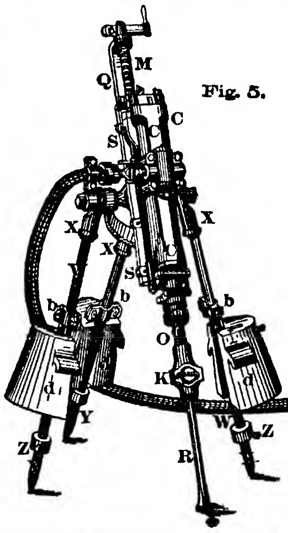

Fig. 5.

Large drills are frequently furnished with an ***automatic* feeding arrangement** in addition to the hand-crank. In this arrangement, when the cylinder requires feeding forward, and when, consequently, the piston is running nearly to

the forward limit of its stroke, the piston presses against a cam projecting into the cyl near the forward end, and presenting an inclined plane to it. The motion of this cam, by means of an exterior axle, running alongside of the cyl and furnished at its top with a dog, turns a ratchet-wheel fixed to the feed-screw. When desired, the automatic feed may be thrown out of gear, and the feed moved by hand.

Art. 29. The tripod legs consist of wrought-iron tubes, W W. These are screwed at their upper ends into sockets, X X. At their lower ends, they receive the pointed and tapering steel bars, Y Y, about 2 or 3 ft long. The legs may be lengthened or shortened by turning the set-screws, Z Z, thus regulating the distance to which the bars, Y Y, can enter the legs. The clamps, *b b*, have L-shaped hooks of ½ inch to 1 inch round iron forged to them. On these hooks **the weights,** *d d*, are hung, which hold the machine down against the upward reaction of its blows.

Art. 30. The following **table** gives the principal **dimensions** of these drills, with the **diams and lengths of holes** to which each is adapted. Size H is used for submarine work, heavy tunneling, and deep rock cutting. G and F for tunneling, street grading, quarrying, and sewer work. E, D, and C for general mining purposes. B is adapted only for very light work. In asking for estimates on drills and compressors, give the fullest possible description (accompanied by a sketch) of the work to be done, stating its present and proposed extent. State whether the work is on the surface or underground. State how far the steam or compressed air will be carried. Give depth of holes to be drilled, nature of rock, &c. Percussion drills are sold without restriction as to the purpose or extent to which they are to be used.

‡ Machine **A** is mounted on a small frame.

Art. 31. The drills of different makers differ chiefly in the methods by which the valve is operated. In some this is done, as in the Ingersoll "Eclipse" drill, Art 26, by the **pres of steam.** In others, the valve is moved by a **lever or tappet,** which projects into the cylinder so as to come into contact with, and be moved by, the piston at each stroke. As these strokes are made with great force some 300 or more times per minute, such valve-gear is necessarily subject to great wear.

Art. 32. In the "**Little Giant Drill,**" made by the **Rand Drill Co.,** the valve, V, Fig 6, is slid backward and forward, in the same direction in which the piston is moving, by the tappet, T, which is pivoted at *p*. The inclined lower corners of this tappet ride up as they come, alternately, in contact with the shoulders, *s s*, of the piston.

Art. 33. In the "**Economizer**" and the "**Slugger**" (Rand Drill Co.) the valve, as in the Ingersoll "Eclipse" drill, is moved by steam, but upon

a quite different principle. In these two drills, there is no steam cushion for the piston to strike against on the down stroke, the force of which is thus more completely expended upon the rock. The cushion behind or above the piston, on the return stroke, is formed by exhaust steam. Both of these drills cut off steam before the completion of either stroke, thus using the steam expansively. On the down stroke, the "Economizer" cuts off earlier than the "Slugger." Hence its name. In both machines the point of cut-off is fixed when the machine is made.

Art. 34. In the improved **Burleigh** drill, the valve, V, Fig 7, is moved by **two** tappets, T T, which are alternately struck by the ends of the piston, P.

Art. 35. In the "Dynamic" rock-drill, invented by **Prof De Volson Wood**, the valve is attached to a valve-piston, V, Fig 8, which is moved backward and forward by steam, which is admitted so as to act alternately upon its two ends. The admission of this steam is controlled by a small auxiliary valve, *a*. A hub on the back of the auxiliary valve fits in the spiral groove shown on the plug, *n*. This plug is constantly pressed downward (as the Fig stands) by steam pressing upon its upper shoulder, but it is lifted at each forward stroke by the conical surface of the piston, P, pressing against its foot. It thus moves constantly up and down, carrying the valve, *a*, with it. By turning the plug, *n*, by means of the adjusting-stem, *s*, the hub of the valve is made to occupy a higher or lower point in the spiral groove, and thus the stroke of the piston may be varied, or may be confined to any part of the cylinder.

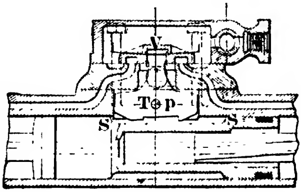

Fig. 6.

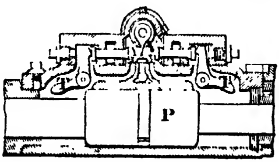

Fig. 7.

In this drill, unlike the Ingersoll, Art. 27, the **piston rotates** while making

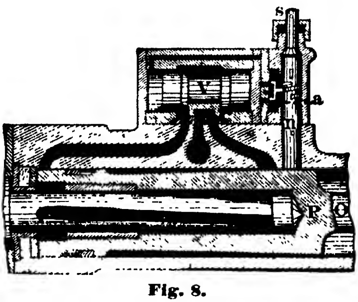

Fig. 8.

the *downward* stroke. **The piston-rod, *o*, is made lighter than in other drills.** This gives a greater surface under the piston for the pressure of the steam on the up stroke, and, consequently, greater lifting power. This is useful when the drill sticks in the hole.

The **tripod legs** are of bar iron. Their length is adjustable.

Art. 36. The **Pierce hand rock-drill** is a percussion drill worked by a crank which turns a disc about 2 ft in diam. The disc has a semi-circular slot, in which works the arm which raises the drill-rod. This arm, in rising, compresses a coil-spring, which, on the down stroke, drives the drill against the rock. An iron ball, weighing 30 lbs or more, is furnished with each machine. This ball may be screwed to the top of the drill-rod, for giving greater force to the blows of the drill. The ball may be used without the spring, by disengaging the latter.

The drill makes about 40 strokes of 10 or 12 ins per minute; and bores holes from ¾ to 2½ ins diam. It can be arranged to drill to depths of 30 ft and over. For sharpening the bits, it has an emery wheel attached, which is turned by the crank. The latter, at such times, is thrown out of gear with the disc.

The drill is mounted on a rectangular two-legged frame, about 5 ft high by 2 ft wide, made of iron tubes. To the top of this frame a third leg is attached, by adjusting which the angle of the drill-rod with the vert may be changed. Like other percussion drills worked by hand-power, this one ceases to work to advantage when said angle exceeds about 45°.

Art. 37. Channeling consists in making long, deep, and narrow cuts in the rock. In this way large blocks can be gotten out without blasting and the consequent danger of fracture. This is ordinarily done by boring a row of holes about an inch apart in the clear, and then breaking down the intermediate spaces by means of a blunt tool, called a **broach.** This is called **broach channeling.** For this purpose a steam drilling machine is mounted upon a hor bar resting upon two pairs of legs. The hor bar is placed over the intended row of holes, and the drill is slid along upon it from one hole to the next. In using the *broach*, the rotating apparatus is thrown out of gear, so that the edge of the broach maintains its position in line with the row of holes

Art. 38. The Saunders patent channeling machine, of the Ingersoll Co, consists of a rock-drilling machine, having, in place of the usual drilling-bit, a gang of tools consisting of a number of chisels, clamped together side by side, and thus forming a cutting tool about 7 ins long by ¾ inch wide. This tool has as many cutting-edges (each as long as the tool is wide) as there are chisels. The machine is supported upon a carriage, moving on a track parallel with the channel to be cut. The tool is of course not rotated; but the rifle-bar, A, Fig 4, is employed to move the carriage along the track about an inch after each blow. The carriage remains stationary while a blow is being struck. Under favorable circumstances **this machine has cut** from 80 to 100 sq ft of channel per day of ten hours. Its **weight,** including carriage, is about 5000 lbs.

A valve is provided, by which, if desired, the **steam may be shut off** from the piston on the down stroke, so that said stroke may be made with only the *weight* of the piston, rod, and drill.

Art. 39. The Ingersoll Co have a special appliance, designed by Mr. W. L. Saunders, C E, for **drilling and blasting rocks under water,** even when they are covered by a considerable depth of mud.

Art. 40. Air compressors for rock-drills, as made and used in this country, are mostly hor, direct-acting engines. That is, the axes of the steam- and air-cylinders are hor; and the piston-rod passes directly from the steam-cylinder into the air-cylinder. A fly-wheel is attached, by a crank and connecting-rod, to the piston-rod. Sometimes the steam-engine is separate from the compressor, and the power is conveyed to the latter by belts or gearing; or water-power may be used in the same way. The air is forced into a receiver, which is generally a plate-iron cylinder, 3 or 4 ft in diam, and 5 to 12 ft long.

If the air- or pumping-cylinder of the compressor is so arranged as to take in air on one stroke only, and force it out into the receiver upon the return stroke, it is **"single-acting."** If, at each stroke, it both takes in and forces out air, it is **"double-acting."** If the compressor has only one air-cylinder, it is **"single."** If it has two, and thus practically consists of two single compressors, it is **"duplex."**

The **valves** may be either **"poppet"** valves, held in place by springs, and operated by the pressure of the air itself; or **slide** valves, operated by eccentrics and rods, as in steam-engines.

The compression of the air develops **heat.** This is removed either by causing cold water to circulate through the air-piston, and through jackets surrounding the air-cylinder; or by injecting it into the air-cylinder in the form of spray. Or both methods may be used together.

Art. 41. The following partial list of Clayton compressors, compiled from data given by the makers, shows the **dimensions** and **performance** of each. We give also a list of their **receivers**.

CLAYTON DOUBLE-ACTING AIR-COMPRESSORS. Partial List.

36	8	1560	40	11	2000
40	6	1600	40	12	2100

The Air-Receivers have brass-face pressure-gauge, glass water-gauge, safety-valve, blow-off valve, try-cocks, flanges and connections to automatic feed on compressor.

TRACTION.

Traction on common roads, and canals; or the power reqd to draw vehicles and boats along them.

The following table shows tolerable approximations to the force in lbs per ton, reqd to draw a stage coach and passengers, up ascents on the Holyhead turnpike road in England, (a fine road,) by horses, as ascertained by means of a dynamometer. The entire weight was 1¼ tons, but in the table, the results are given per single ton. From the nature of such cases, no great accuracy is attainable.

Proportional Ascent.	Ascent in Ft. per Mile	At 4 Miles per Hour.	At 6 Miles per Hour.	At 8 Miles per Hour.	At 10 Miles per Hour.
		Lbs.	Lbs	Lbs.	Lbs.

The following results most of them with the same instrument, are also in lbs per ton, with a four-wheeled wagon, at a slow pace, on a level, and the roads in fair condition.

On a cubical block pavement .. .. 32 lbs per ton..........to 50.
" McAdam road, of small broken stone.............. 62 " " " probably to 75.
" gravel road ... . 140 " " "
" Telford road, of small stone on a paving of spawls 46 " " " " " 75.
" broken stone on a bed of cement concrete .... 46 " " " " " 75
" common earth roads.. .... 200 to 300. On a plank road 30, to 50 lbs

The tractive power of a horse diminishes as his speed increases: and perhaps, within certain limits, say from ¾ to four miles per hour, nearly in inverse proportion to it. Thus, the average traction of a horse, *on a level*, and actually pulling for 10 hours in the day, may be assumed approximately as follows

Miles per hour.	Lbs. Traction.	Miles per hour.	Lbs. Traction.
¾	333 33	2¼	111.11
1	250.	2½	100.
1¼	200.	2¾	90.91
1½	166 66	3	83.33
1¾	142.86	3½	71.43
2	125.	4	62.50

If he works for a smaller number of hours, his traction may increase as the hours diminish; down to about 5 hours per day and for speeds of about from 1¼ to 3 miles per hour. Thus, for 5 hours per day his traction at 2½ miles per hour will be 200 lbs, &c. When ascending a hill, his power diminishes so rapidly, from having partially to raise his own weight, (which averages about 1000 to 1100 lbs,) that up a slope of 5 to 1, he can barely struggle along without any load. On such an ascent, he must exert a force equal to 439 lbs per ton, or of 196 lbs for the 1000 lbs of his own weight. Assuming that on a level piece of good turnpike, he would when hauling a cart and load, together weighing 1 ton, have to exert a traction of 60 lbs; then on ascending a hill of 4° inclination, (or 1 in 14 3; or 369¼ ft per mile,) he would have to exert 156 lbs, against the gravity of the 1 ton; and 67 lbs, against that of his own weight, or 223 lbs in all. He may, for a few mins, exert without injury, about twice his regular traction. This calculation shows that up a hill of 4°, an average horse is fully tasked in drawing a total load of one ton; and should, therefore, be allowed, in such a case, to choose his own gait; and to rest at short intervals. A fair load for a single horse with a cart, at a variable walking pace, working 10 hours per day, on a common undulating road in good order, is about half a ton, in addition to the cart, which will be about half a ton more. With two horses to this same cart, the *load* alone may be about 1¼ tons.

Rem. Since the action of gravity is the same on good roads and bad ones, it follows that **ascents become more objectionable the better the road is.** Thus, on an ascent of 2°, or 184.4 ft. per mile, gravity alone requires a traction of 78 lbs per ton'

which is about 10 times that on a level railroad at 6 miles an hour, but only about equal to that on a level common turnpike road, at the same speed. Therefore, (to speak somewhat at random,) it would require 10 locomotives instead of 1, but only 2 horses instead of 1. A grade of 1 in 35, or 150 ft to a mile; or 1° 38', is about the steepest that permits horses to be driven down a hard smooth road, in a fast trot, without danger. It should, therefore, not be exceeded except when absolutely necessary, especially on turnpikes.

On canals and other waters, the liquid is the resisting medium that takes the place of friction on level roads. But unlike friction its resistance varies as the squares of the vels; at least from the vel of 2 ft per sec, or 1.364 miles per hour; to that of 11½ ft per sec, or 7.84 m per h. As the speed falls below 1⅜ m per h, the resistance varies less and less rapidly; and this is the case whether the moved body floats partly above the surface; or is entirely immersed. In towing along stagnant canals, &c, the vel is usually from 1 to 2½ m per h, for freight most frequently from 1½ to 2. Less force is required to tow a boat at say 2 m per h, where there is no current, than at say 1¼ m per h, against a current of ¾ m per h, because in the last case the boat has to be *lifted up* the very gradual inclined plane or slope which produces the current.

The force required to tow a boat along a canal depends *greatly* upon the comparative transverse sectional areas of the channel, and of the immersed portion of the boat. When the width of a canal at water-line is at least 4 times that of the boat; and the area of its transverse section as great as at least 6½ times that of the *immersed* transverse section of the boat, the towing at usual canal vels will be about as easy as in wider and deeper water. With less dimensions, it becomes more difficult. (D'Aubuisson.) Much also depends on the shape of the bow and other parts of the boat; and on the proportion of its length to its breadth and depth. Hence it is seen that the mere weight of the load is by no means so controlling an element as it is on land. The whole subject, however, is too intricate to be treated of here. Morin states that naval constructors estimate the resistance to sailing and steam vessels at sea, at but from about .5 to .7 of a lb for every sq ft of immersed transverse section, when the vel is 3 ft per sec, or 2.046 miles per hour. It is far greater on canals.

On the Schuylkill Navigation of Pennsylvania, of mixed canal and slackwater, for 108 miles, the regular load for 3 horses or mules, is a boat of very full build; and no keel; 100 ft long, 17½ ft beam; and 8 ft depth of hold, drawing 5½ ft when loaded. Weight of boat about 65 tons, load 175 tons of coal, (2240 lbs,) total weight 240 tons, or 80 tons per horse or mule. On the down trip with the loaded boats, for 4 days, the animals are at work, *actually towing*, (except at the locks,) for 18 hours out of the 24; thus exceeding by far the limits of time usually allowed for continuous effort.

On the canal sections, (which have 60 ft water-line; and 6 ft depth,) the speed is 1¾ miles per hour; and on the deep wide pools, 2 miles.

On the up trip with the empty 65 ton boats, the average speed is about 2½ miles per hour. The empty boats draw 16 to 18 ins water, and frequently keep on without stopping to rest day or night through the entire distance of 108 miles. The animals generally have 2 or 3 days' rest at each end of the trip, but are materially deteriorated at the end of the boating season.

If our preceding assumption of 143 lbs traction of a horse at 1¾ miles per hour, is correct, the traction of the loaded boats on the canal sections is $\frac{143 \text{ lbs}}{80 \text{ tons}} = 1.83$ lbs per ton.

The intelligent engineer and superintendent of the Sch Nav, James F Smith, gives as the results of his own extensive observation, that one of these large boats loaded (240 tons in all) may, without distressing the animals, be drawn along the canal sections, for 10 hours per day, as follows: By one average horse or mule, at the rate of 1 mile; by two animals, at 1½ miles; and by three, at 1¾ miles per hour. When four animals are used the gain of time is very trifling. At a time of rivalry among the boatmen, one of them used 8 horses, but with these could not exceed 2½ miles per hour in the canal portions. Two or more horses together cannot for hours pull as much as when working separately.

If our preceding short table of the traction of a horse at diff vels for 10 hours is correct, then the traction of the above loaded coal boats (240 tons) on the canal sections of the navigation is as follows: The last column shows the traction in lbs per sq ft of area of immersed transverse section where largest; viz, about 95 sq ft.

Horses.	Miles per Hour.		Lbs. per Ton.	Lbs. per Sq Ft.
1	1	$\frac{250}{240}$	1.04	2.63
2	1½	$\frac{333}{240}$	1.39	3.50
3	1¾	$\frac{428}{240}$	1.78	4.50
3 on pools	2	$\frac{375}{240}$	1.56	3.95
8	2½	$\frac{800}{240}$	3.33	8.42
3 up trip	2½	$\frac{300}{65}$	4.61	12.50

Lachine Canal, Canada, 120 ft wide at water-line; 80 ft at bottom; depth on mitre sills 9 ft, 6 horses tow loaded schooners with ease.

Before the enlargement of the **Erie canal,**† its dimensions were 40 ft water line, 28 ft bottom; 4 ft depth of water. The average weight of the boats was about 30 tons. With 75 tons of load, or 105 tons total, they were towed by 2 horses, at the rate of about 2 miles per hour, which by our table gives a traction of nearly 2.4 lbs per ton. The boats were about 80 ft long, 14 ft beam, full 3½ ft draught loaded; hence the traction by our table would be about 5.7 lbs per sq ft of immersed transverse section.

† Length 363 miles; cost $19680 per mile. The enlarged canal has 70 ft; 42 ft; and 7 ft of water; and cost $80600 per mile for the enlargement only. The cost of the several canals in Pennsylvania has ranged between $25000 and $50000 per mile.

While, for 82-ton loaded boats on a smaller canal, (the boats nearly touching bottom,) the traction at 1¾ miles, would be 3½ ℔s per ton, or about twice as great as the above 1.78 ℔s. It also would be 5.7 ℔s per sq ft of immersed section.

ANIMAL POWER.

Art. 1. So far as regards horses, this subject has been partially considered under the preceding head, Traction. All estimates on this subject must to a certain extent be vague, owing to the diff strengths and speeds of animals of the same kind; as well as to the extent of their training to any particular kind of work. Authorities on the subject differ widely; and sometimes express themselves in a loose manner that throws doubt on their meaning. We believe, however that the following will be found to be as close approximation to practical averages as the nature of the case admits of with our present imperfect knowledge. We suppose a good average trained horse weighing not less than about ½ a ton, well fed and treated. Such a one, when actually walking for 10 hours a day, at the rate of 2½ miles per hour, on a good *level* road, such as the tow path of a canal, or a circular horse-path,* **can exert a continuous pull, draught, power, or traction, of 100 lbs.**

Now, 2½ miles per hour, is 220 ft per min, or 3⅔ ft per sec; and since 10 hours contain 600 min, his day's work of actual hauling on a level, at that speed, amounts to

$$\overset{\text{min}}{600} \times \overset{\text{ft}}{220} \times \overset{\text{℔s}}{100} = 13\,200\,000 \text{ ft ℔s per day.}$$

Or, 22000 ft-℔s per min, or 366⅔ ft-℔s per sec.† Which means that he exerts force enough during the day to *lift* 13 200 000 ℔s 1 foot high; or 1 320 000 ℔s 10 feet high; or 132 000 ℔s 100 ft high, &c. He may exert this force either in *traction* (hauling) or in *lifting* loads. If he has to raise a small load to a great height, the machinery through which he does it must be so geared as to gain speed, at the loss (commonly but improperly so expressed) of power. Whether he lifts the great weight through a small height, or the small weight through a great height, he exerts precisely the same amount of force or power.

Experience shows that within the limits of 5 and 10 hours per day, (the speed remaining the same, **the draft of a horse may be increased in about the same proportion as the time is diminished:** so that when working from 5 to 10 hours per day, it will be about as shown in the following table. Hence, the total amount of 13 200 000 ft-℔s per day may be accomplished, whether the horse is at work 5, 6, or 8, &c, hours per day.‡ This, of course, supposes him to be actually lifting or hauling *all the time;* and makes no allowance for stoppages for any purpose.

Table of draft of a horse, at 2½ miles per hour, on a level.

Hours per day.	Lbs.	Hours per day.	Lbs.
10	100	7	$142\frac{6}{7}$
9	$111\frac{1}{9}$	6	166⅔
8	125	5	200

Experience also shows that at speeds between ¾ and 4 miles an hour, his force or draught will be inversely in proportion to his speed. Thus, at 2 miles an hour, for 10 hours of the day, his draught will be

$$\overset{\text{miles}}{2} : \overset{\text{miles}}{2\tfrac{1}{2}} :: \overset{\text{℔s}}{100} : \overset{\text{℔s}}{125} \text{ draught}$$

At 1½ miles, it would be 166⅔ ℔s; at 3 miles, 83⅓ ℔s; and at 4 miles, 62½ ℔s; as per table in Traction.

Therefore, in this case also, the entire amount of his day's work remains the same;§ and within

---

* To enable a horse to work with ease **in a circular horse-walk,** its diam should not be less than 25 ft, 30 or 35 would be still better.

† **A nominal horse-power** is 33000 ft-℔s per minute; this being the rate assumed by Boulton and Watt in selling their engines: so that purchasers wishing to substitute steam for horses, should not be disappointed. Their assumption can be carried out by a very strong horse day after day for 8 or 10 hours; but as the engine can work day and night for months without stopping, which a horse cannot, it is plain that a one-horse engine can do much more work than any one such horse. Hence many object to the term horse-power as applied to engines; but since everybody understands its plain meaning, and such a term is convenient, it is not in fact objectionable. Boulton and Watt meant that a one-horse engine would at any moment perform the work of a very strong horse. An *average* horse will do but 22000 ft-℔s per min.

‡ It is plain that although the *day's* labor will be the same, that of an hour, or of a min, will vary with the number of hours taken as a day's work. It must be remembered that a *working day* of a given number of hours, by no means implies, in every case, that number of hours of *actual work;* but includes intermissions and rests.

§ **This remark about speed will not apply to loads towed through the water.** Thus, if his draught at 2 miles an hour be 125 ℔s; and at 4 miles, 62½ ℔s; he will *on land* draw loads in these proportions; but in hauling a boat *through the water* at the greater speed, he has to encounter the increased resistance of the *water* itself; which resistance at 4 miles is much more than twice as great as at 2 miles; probably 4 times as great. Therefore, at 4 miles on a canal, his draught of 62½ ℔s would not suffice for *a load* half as great as he could tow with his draft of 125 ℔s at 2 miles.

all the foregoing limits of hours and speed, may be practically taken to be about 13 200 000 ft-lbs per day; or 22000 ft-lbs per min of a day of 10 hours. But it does not follow that the horse can always in practice actually *lift loads* at that rate, because generally a part of his power is expended in overcoming the *friction* of the machinery which he puts in motion; and moreover, the nature of the work may require him to stop frequently; so that in a *working day* of 8 or 10 hours, the horse may not actually be *at work* more than 5, 6, or 7 hours.

As a rough approximation, to allow for the waste of force in overcoming the friction of hoisting machinery, and the weight of the hoisting chains, buckets, &c, we may say that **the useful or paying daily net work of a horse, in hoisting by a common gin,** is about 10 000 000 ft-lbs. That is, he will raise equivalent to 10 000 000 lbs net of water, or ore, &c, 1 foot. The load which he can raise at once, including chains, bucket, and an allowance for friction, will be as much greater than his own direct force, as the diam of the horse walk is greater than that of the winding drum, and it will move that much slower than he does. His own direct force will vary according to the number of hours per day that he may be required to work, as in the foregoing table. With these data, the size of the buckets can be decided on, and of these there should be at least two, so that the empty one at the bottom may be filled while the full one at top is being emptied; so as to save time. The same when the work is done by men.

Art. 2. A practised laborer hauling along a level road, by a rope over his shoulders; or in a circular path, pushing before him a hor lever, at a speed of from $1\frac{1}{2}$ to 3 miles per hour, exerts about $\frac{1}{6}$ part as much force as a horse; or 2 200 000 ft-lbs per day; or $3666\frac{2}{3}$ ft-lbs per min of a day of 10 hours of actual hauling or pushing.

But laborers frequently have to work under circumstances less advantageous for the exertion of their force than when hauling or pushing in the manner just alluded to; and in such cases they cannot do as much per day. Thus in turning a winch or crank like that of a grindstone, or of a crane, the continual bending of the body, and motion of the arms, is more fatiguing. **The size of a winch should not exceed 18 ins,** or the rad of a circle of 3 ft diam; and against it a laborer can exert a force of about 16 lbs, at a vel of $2\frac{1}{2}$ ft per sec, or 150 ft per min, making very nearly 16 turns per min; for 8 hours per day. To these 8 hours an addition must be made of about $\frac{1}{4}$ part, for short rests. Or if a *working day* is taken at 8 or 10, &c, hours, $\frac{1}{5}$ part must generally be taken from it for such rests. On the foregoing data an hour's *work* of 60 min of *actual hoisting* would be

$$\overset{\text{lbs}}{16} \times \overset{\text{ft}}{150} \times \overset{\text{min}}{60} = 144000 \text{ ft-lbs};$$

or, deducting $\frac{1}{5}$ part for rests, 115200 ft lbs per hour of *time, including rests*. In practice, however a further deduction must be made for the fric of the machine, and for the wt of the hoisting chains; and in case of raising water, stone, ore, &c, from pits, for the wt of the buckets also. As a rough average we may assume that these will leave but 100 000 ft lbs of paying, or useful work per hour; that is, that **a man at a winch will actually lift equivalent to 100000 lbs of water, ore, &c, 1 foot high per hour's time, including rests.** This is equal to $1666\frac{2}{3}$ ft lbs per min of a day of 10 hours including rests. Therefore, in a day of 10 working hours he would raise 1 000 000 lbs net, 1 foot high, **or just $\frac{1}{10}$ part of what a horse would do with a gin** in the same time. We have before seen that in hauling along a level road, he can at a slow pace perform about $\frac{1}{6}$ of the daily duty of a horse. He may also work the winch with greater force, say up to 30 or even 40 lbs, but he will do it at a proportionately slower rate; thus, accomplishing only the same daily duty. **With a gin, like those for horses,** but lighter, with 2 or more buckets, a practised laborer will in a working day of 10 hours, raise from 1 200 000 to 1 400 000 ft-lbs net of water, ore &c. With a shallow well or pit, more time is lost in emptying buckets than in a deep one; but the deep one will require a greater wt of rope. To save time in all such operations on a large scale, there should be at least two buckets; the empty one to be filled while the full one is being emptied. It is also best to employ 2 or more men to hoist at the same time, by winches, at both ends of the axis; and the men will work with more ease if the winches are at right angles to each other. Each winch handle may be long enough for 2 or 3 men. An extra man should be employed to empty the buckets. He may take turns with the hoisters. The same remarks apply in some of the following cases.

On a treadwheel a practised laborer will do about 40 per cent more daily duty than at a winch; or in a working day * of 10 hours, including rests, he will do about 1 400 000 ft-lbs. And he can do this whether he works at the outer circumf of the wheel, stepping upon foot-boards, or tread-boards, on a level with its axis; or walks inside of it near its bottom. In both cases he acts by his wt, usually about 130 to 140 lbs, and not by the muscular strength of his arms. When at the level of the axis, his wt acts more directly than when he walks on the bottom of the wheel; but in the first case he has to perform a slow and fatiguing duty resembling that of walking up a continuous flight of steps; while in the second he has as it were merely to ascend a very slightly inclined plane; which he can do much more rapidly for hours, with comparatively little fatigue: and this rapidity compensates for the less direct action of his wt. Therefore, in either case, as experience has shown, he accomplishes about the same amount of daily duty. Treadwheels may be from 5 to 25 ft in diam, according to the nature of the work. They are generally worked by several men at once, and may at times be advantageously used in pile-driving, as well as in hoisting water, stone, &c.

By a good common pump, properly proportioned, a practised laborer will in a day of 10 working hours, raise about 1 000 000 ft lbs of water, net.†

Bailing with a light bucket or scoop, he can accomplish about 200 000 ft lbs net of water. **By a bucket and swape,** (a long lever working vertically, and weighted at one end so as to balance the full bucket hung from the other; often seen at country

---

* The working day must be understood to include necessary rests, and such intermissions as the nature of the work demands; but does not include time lost at meals. A *working day* of 10 hours may, therefore, have but 8, 7, or 6, &c hours of *actual labor*. This will be understood when we hereafter speak of a working day, or simply a day.

† Desaguliers's estimates of daily work of men and horses exceed the above, but are evidently too great

wells,) 600 000 to 800 000. In the last he has only to pull down the empty bucket, and thereby raise the counterweight. **By 2 buckets at the ends of a rope suspended over a pulley,** 500 000 to 600 000. Here he works the buckets by pulling the rope by hand.

By a tympan, or tympanum,* worked by a treadwheel, about 1 200 000 to 1 400 000.

By a Persian wheel,† a chain-pump, a chain of buckets,‡ or an Archimedes screw, all worked by a treadwheel, from 800 000 to 1 000 000 ft-lbs. Of these four, the first three lose useful effect by either spilling, leaking, or the necessity for raising the water to a level somewhat higher than that at which it is discharged.

When any of the five foregoing machines are worked by men at winches, the result will be about ⅕ less than by treadwheels. They are all frequently worked also by either steam, water, or horse-power.

By walking backward and forward, on a lever which rocks on its center, a man may, according to Robison's Mech Philosophy, perform a much greater duty than by any of the preceding modes. He states that a young man weighing 135 lbs, and loaded with 30 lbs in addition, worked in this manner for 10 hours a day without fatigue; and raised 9¼ cubic feet of water, 11½ ft high per min. This is equal to 3 984 000 ft lbs per day of 10 hours; or 6640 ft lbs per min; or nearly $\frac{4}{10}$ of the net daily work of a horse in a gin.

A laborer standing still, can barely sustain for a few min, a load of 100 lbs, by a rope over his shoulder, and thence passing off hor over a pulley. And scarcely as much, when (facing the load and pulley) he holds the end of a hor rope with his hands before him. He cannot push hor with his hands at the height of his shoulders, with more than about 30 lbs force.

Weisbach states from his own observation, that 4 practised men raised a **dolly** (a wooden beetle or rammer, of wood; with 4 hor projecting round bars for handles) weighing 120 lbs, 4 ft high, at the rate of 34 times per min, for 4½ min; and then rested for 4½ min; and so on alternately through the 10 hours of their working day. Therefore, 5 of these hours were lost in rests; and the duty performed by each man during the other 5 hours, or 300 mins, was

$$\frac{120 \times 4 \times 34 \times 300}{4} = 1\,224\,000 \text{ ft-lbs.}$$

In the old mode of driving piles, where the ram of 400 to 1200 lbs suspended from a pulley, was raised by 10 to 40 men pulling at separate cords, from 35 to 40 lbs of the ram were allotted to each man, to be lifted from 12 to 18 times per min, to a height of 3½ to 4½ feet each time, for about 3 min at a spell, and then 3 min rest. It was very laborious; and the gangs had to be changed about hourly, after performing but ½ an hour's actual labor.

Hauling by horses. See Traction. When working all day, say 10 working hours, the average rate at which a horse walks while hauling a full load, and while returning with the empty vehicle, is about 2 to 2½ miles per hour; but to allow for stoppages to rest, &c, it is safest to take it at but about 1.8 miles per hour, or 160 ft per min. The time lost on each trip, in loading and unloading, may usually be taken at about 15 min. Therefore, to find the number of loads that can be hauled to any given dist in a day, first find the time in min reqd in hauling one load, and returning empty. Thus: div twice the dist in ft to which the load is to be hauled; or in other words, div the length in ft, of the round trip, by 160 ft. The quot is the number of min that the horse is in motion during each round trip. To this quot add 15 min lost each trip while loading and unloading; the sum is the total time in min occupied by each round trip. Div the number of min in a working day (600 min in a day of 10 working hours) by this number of min reqd for each trip; the quot will be the number of trips, or of loads hauled per day.

Ex. How many loads will a horse haul to a dist of 960 ft, in a day of 10 working hours, or 600 min?

Here, $960 \times 2 = 1920$ ft of round trip at each load. And $\frac{1920}{160} = 12$ min, occupied in walking. And $12 + 15$ (in loading, &c) $= 27$ min reqd for each load. Finally, $\frac{600}{27} = \frac{\text{min in 10 hours}}{\text{min per trip}} = 22.2$, or say 22 trips, or loads hauled per day.

Table of number of loads hauled per day of 10 working hours. The first col is the distance to which the load is actually hauled; or half the length of the round trip. The cost of hauling per load, is supposed to be for one-horse carts; the driver doing the loading and unloading; rating the expense of horse, cart, and driver at $2 per day.

---

* The tympan revolves on a hor shaft; and is a kind of large wheel, the spokes, arms, or radii of which are gutters, troughs, or pipes, which at their outer ends terminate in scoops, which dip into the water. As the water is gradually raised, it flows along the arms of the wheel to its axis, where it is dischgd. The scoop wheel is a modification of it. It is an admirable machine for raising large quantities of water to moderate heights. We cannot go into any detail respecting this and other hydraulic machines.

† A kind of large wheel with buckets or pots at the ends of its radiating arms; revolves on a hor axis; discharges at top. The buckets are attached loosely, so as to hang vert, and thus avoid spilling until they arrive at the proper point, where they come into contact with a contrivance for tilting and emptying them. The noria is similar, except that the buckets are firmly held in place, and thus spill much water. It is therefore inferior to the Persian wheel.

‡ An endless revolving vert chain of buckets. D'Aubuisson and some others erroneously call this the noria. It is an effective machine.

Dist Feet	No. of Loads.	Cost per Load	Dist. Feet.	No. of Loads.	Cost per Load	Dist Miles	No of Loads.	Cost per Load
		Cts			Cts			Cts
50	38	5 26	1500	18	11 11	1	7	28 57
100	37	5 41	2000	15	13 33	1¼	6	33 33
200	34	5 88	2500	13	15 39	1½	5	40 00
300	32	6 25	3000	11	18 18	2	4	50 00
400	30	6 67	3500	10	20 00	3	3	66 67
600	27	7 41	4000	9	22 22	4	2	100 00
1000	22	9 09	5000	7	28 57	9	1	200 00

If the loading and unloading is such as cannot be done by the driver alone, but requires the help of cranes, or other machinery, an addition of from 10 to 50 cts per load may become necessary. Hauling can generally be more cheaply done by using 2 or 3 horses, and one driver to a vehicle. The neat load per horse, in addition to the vehicle, will usually be from ½ to 1 ton, depending on the condition, and grades of the road. From 13 to 15 cub ft of solid stone; or from 23 to 27 cub feet of broken stone, make 1 ton. **In estimating for hauling rough quarry stone for drains, culverts, &c,** bear in mind that each cub yard of common scabbled rubble masonry, requires the hauling of about 1.2 cub yds of the stone as usually piled up for sale in the quarry, or about ⅔ of a cub yd of the original rock in place. **A cub yd of solid stone, when broken into pieces, usually occupies about 1.9 cub yds perfectly loose;** or about 1¾ when piled up. A strong cart for stone hauling, will weigh about ¾ ton, or 1500 lbs, and will hold stone enough for a perch of rubble masonry, or say 1.2 pers of the rough stone in piles. The average weight of a good working horse is about ½ a ton.

Morin gives the following results from careful experiments made by him for the French Government. The draft of the same wheeled vehicle on a road, may in practice be considered to be,

1st. On hard turnpikes, and pavements: in proportion to the loads; inversely as the diams of the wheels; and nearly independent of the width of tire. It increases to uncertain extents with the inequalities of the road, the stiffness (want of spring) of the vehicle, and the speed; (considerably less than as the square roots of the last.)

2d. On soft roads, the draft is less with wide tires than with narrower ones; and for farming purposes he recommends a width of 4 ins. With speeds from a walk to a fast trot, the draft does not vary sensibly.

TRUSSES.

INTRODUCTION.

General Principles.

1. Truss Design a Specialty. The design, construction and erection of trusses have become a specialty, to which persons confine themselves more or less exclusively, and thus attain a degree of expertness beyond the reach of the general engineer.* The latter, however, should have a knowledge of the subject, sufficient at least to enable him to form a well-grounded opinion of the general merits of a design and to guard him against the adoption of one involving serious imperfections. In a volume like this we can discuss only general principles.

2. The Truss Principle. Theoretically, a truss consists of a number of straight bars, joined, near their ends, by perfectly flexible joints, loaded only at these joints, and so arranged that all its internal stresses are sustained by its members, and only the vertical † pressures, due to the weights of the truss and its load, are transmitted to the abutments.

3. Distinction between Beams and Trusses. When a solid beam (Fig. 2, ¶ 7, Transverse Strength) bends, under its own weight or under that of its load, all the fibers above the neutral axis are compressed, while all those below are extended; and the resulting change of length, in each fiber, is proportional to the distance of the fiber from the neutral axis; but, in a truss, the loads (including the weight of the truss itself) are theoretically regarded as divided into portions which are concentrated at the joints between the members and which act through the cens of grav of their cross-sections. So placed, the stresses caused by them could not act transversely of the members, as in a beam, causing so-called secondary stresses, but must act longitudinally or axially of the members, and must be uniformly distributed over their entire cross-sectional areas. This is the distinguishing feature of all trusses.

4. In such a truss the material would be used most economically, and the stresses in each piece and in each part of such piece could be readily and accurately determined.

5. In the truss of a well-designed bridge or roof, this ideal condition is approximated by using, for the principal members, straight and rather slender pieces, and by so distributing the extraneous load that it shall be applied only at the joints between the members, thus subjecting them chiefly to forces acting at their ends and in the directions of their lengths. In pin-connected trusses (see ¶ 175) the joints are practically flexible.

Most of the trusses in common use consist of two long members, usually horizontal (but see ¶ 49), called **chords,** extending throughout the span and connected by **web members,** which are sometimes all inclined, and sometimes alternately vertical and inclined. Inclined web members are called **diagonals.**

6. Ties and Struts. A member sustaining tension is called a rod or tie. One sustaining compression is called a strut or post. One capable of sustaining both tension and compression is called a tie-strut or a strut-tie.

7. The dimensions of a truss are usually measured along the center lines of its members; and, in pin-connected trusses, the pins are placed at the intersections of these lines Hence, the measurements are usually made from "center to center of pins."

8. In a plate girder, the flanges are usually regarded as performing the function of the chords of a truss, and the web as performing that of the web members of a truss.

---

* Railroad companies and municipal corporations frequently prepare their own bridge specifications; but the general proportions, number of panels, etc., are often left to the judgment of the bidders.

† We here suppose the truss to be loaded vertically. If the load is otherwise applied, as in the case of the wind pressure upon a horizontal bracing truss, the pressure on the supports may be horizontal, or otherwise inclined to the vertical, but all the internal stresses are still sustained by the truss members.

Loading.

9. Dead and Live Load. In bridges, we distinguish between the "dead" and the "live" load; the dead load comprising the weight of the permanent structure—*i. e.*, of the bridge itself, with its trusses, bracing and floor system; while the live load comprises any temporary and extraneous loads, such as engines, cars, horses, vehicles, foot passengers, etc., which may come upon the bridge

10. The dead load is usually distributed uniformly along the span, but the loaded chord (that carrying the roadway) of course usually receives a greater share of it than the unloaded chord. The live load comes only upon the loaded chord. In determining stresses, it is usual to consider the weight of live load and of floor system as being on the loaded chord, and the rest of the dead load as divided equally between the two chords. It sometimes happens, however, that both the upper and the lower chords carry roadways. They must then, of course, both be treated as "loaded," though not necessarily *equally* loaded; for one may carry a railway while the other carries only a highway.

Unsymmetrical Loading. Counterbracing.

11. Unsymmetrical Loading. In Figs. 2 to 10, the loads are supposed to be placed symmetrically.

12. If this could be the case in practice, the compression members would never be called upon to resist tension, or the tension members to resist compression; and the trusses in Figs. 2 to 10 would suffice (supposing each member to have sufficient strength), even though the compression members were incapable of resisting tension and vice versa. Thus, the tension members might be flexible chains, and the compression members might be posts, merely abutting against supports at their ends.

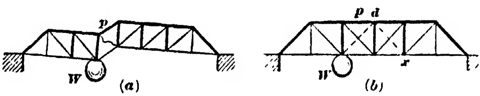

Fig. 1.

13. But in a truss, Fig. 1 (*a*), with a flexible tie in the panel, *p*, as shown, the load W, unsymmetrically placed, would cause failure, as indicated.

14. Counterbracing. To prevent this, those members which, under moving loads, may be subjected alternately to both tension and compression may be so constructed as to be able to resist both kinds of stress. That is to say, the tension members may be so stiffened as to be capable of acting as posts, and the ends of the compression members so connected to the chords that those members can also act as ties. This is the expedient usually employed in trusses without vertical web members.

15. Counters. In trusses with rectangular panels, the distortion, Fig. 1 (*a*), caused by unsymmetrical loading, is usually prevented by the introduction of additional members called counterbraces, or counters, in distinction from the "main" members, which last are designed to resist the normal stresses due to uniformly or symmetrically distributed loads. Thus, in Fig 1 (*b*) the unsymmetrical load, W, tends to convert the rectangle, *p*, into a rhomboid, by lengthening its diagonal, W *d*; and this may be prevented by the introduction of an oblique tension member (counter) in the line of that diagonal, as shown by dotted line. For a similar reason, such a counter is inserted also in the corresponding panel, *x d*.

16. Triangles. It will be noticed that the introduction of counters reduces the truss to a framework made up exclusively of *triangles*.

17. It might at first sight appear that the several parts of a bridge truss must be most strained when covered from end to end with its maximum load; but this is true only of the chord and of the *main* diagonals and verticals near the *ends* of the truss. The other web members may be more strained by a *part* of the load, placed unsymmetrically on the truss; so that, although correctly proportioned for a full load, they may be too weak for a

partial one. If all be made as strong as the end ones, they will, it is true, be safe for a passing load; but this would require an expense of material that would be justified only in the case of moderate spans, especially of wood, in which the additional trouble and expense of getting out and fitting together pieces of many different sizes may more than counterbalance the saving in material.

18. In large bridges, where the live load is small, relatively to the dead load, but little counterbracing is needed, and that at and near the center only; whereas, in a very light bridge, the counters should extend from the center, where they are most strained, to near the ends, where the strain upon them is least.

Cross-bracing.

19. Bracing between Trusses. Advantage is taken of the proximity of the two or more trusses of a bridge, standing side by side, to connect them by cross-bracing, thus giving to the entire structure far greater lateral stability than would be possible in the single trusses.

20. Thus, **lateral bracing,** Fig. 39, consists of horizontal trusses placed between the two upper chords of the main trusses, or between the two lower chords, or both; the chords of the main trusses acting also as the chords of the lateral trusses. The lateral bracing prevents lateral deflection of the chords.

21. Sway bracing, Fig. 64 (*c*) (called also diagonal, cross, vibration and wind bracing), consists of short trusses (usually vertical) crossing the bridge transversely and thus connecting the two trusses. The sway bracing has its own chords, but uses parts of the posts of the main truss as its end posts.

22. Portal bracing, Fig. 54 (*a*), consists of sway bracing (usually in an inclined plane) joining the tops of the end posts in trusses of sufficient depth to permit its use. The portal bracing, with the end posts, forms a portal through which trains, etc., enter the bridge.

Types of Trusses.

23. The simplest form of truss consists of a single triangle, Figs. 2 (*a*) and (*b*). In Fig. (*a*) the load produces compression in the rafters, tension in the chord or tie rod,* and compression (= the tension in the chord) between the heads of the rafters; in Fig. (*b*) vice versa.

24. The truss shown in Fig. 2 (*a*) is in common use for roofs of small span, as in dwellings. In practice, it is of course loaded along the rafters, and not only at the apex as in Fig. (*a*); but, in calculating the stresses in truss members, we commonly first assume that the loads are concentrated at the *intersections* of the members. The effect of their actual distribution *along* the members is then determined separately, treating the members as beams.

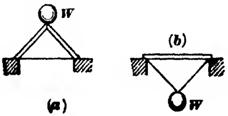

Fig. 2.

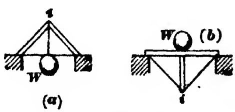

Fig. 3.

25. In Fig. 3 (*a*) (called a King truss), the vertical tie (improperly called a King post), and in Fig. 3 (*b*) the vertical post, simply carries the weight of the load to the apex, *i*, where it produces the same effect as in Figs. 2 (*a*) and (*b*).

26. Hence, neglecting the weights of the vertical tie and other members, the stresses, caused by a given load, W, in the diagonals, and in the horizontal tie, Fig. 3 (*a*), are the same (not only in character, but also in amount) as those produced by an equal load, W, in Fig. 2 (*a*). Similarly, those in Fig. 3 (*b*) correspond with those in Fig. 2 (*b*).

---

* In Figs. 2 to 12, and 14 to 17, double or heavy lines indicate posts or struts, and light lines indicate ties

27. Figs. 4, 5, and 6, giving modifications of the simple forms shown in Figs. 2 and 3, illustrate in principle most of the bridge trusses in common use for spans up to 300, 400 or even 500 feet. See Figs. 7 to 10, ¶¶ 35, etc.

28. In Figs. 4, 5, and 6, there is an upper chord, in compression; and a lower chord, in tension; the shorter chord sustaining the compression between the heads of the rafters, Figs. 2 (*a*) and 3 (*a*), or the horizontal tension between the feet of the diagonals, Figs. 2 (*b*) and 3 (*b*). Figs. 4 (*a*) and 5 (*a*) are modifications of Figs. 2 (*a*) and 3 (*a*); Figs. 4 (*b*) and 5 (*b*) of Figs. 2 (*b*) and 3 (*b*): Fig. 6 (*a*) of Fig. 2 (*a*), and Fig. 6 (*b*) of Fig. 2 (*b*)

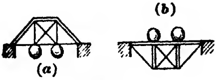

Fig. 4.

29. Figs. 4 (*a*) and 4 (*b*) may be regarded as showing Figs. 3 (*a*) and 3 (*b*) respectively, with the vertical member, as well as the load, split in two, and the two parts separated by horizontal straining pieces. If the loads are placed symmetrically, so that the horizontal pressures, Fig. 4 (*a*), or tensions, Fig. 4 (*b*), on the two ends of the shorter chord, are equal, the two diagonal counters in the center are unnecessary.

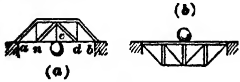

Fig. 5.

30. Howe and Pratt Systems. In Fig. 5 (*a*) the vertical web members are in tension, and the diagonals are in compression, embodying the "Howe" principle, used in bridges with wooden diagonals; while in Fig. 5 (*b*) the verticals are in compression, and the diagonals in tension, embodying the "Pratt" principle, used in bridges with metal diagonals. In such bridges long compression members are objectionable.

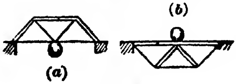

Fig. 6.

31. Warren or Triangular Trusses. In Fig. 6, illustrating the "Warren" or "triangular" truss, the web members are all diagonal, and are alternately in tension and in compression. They divide the truss profile into *isosceles* triangles.

32. Through, Deck and Pony Spans. Figs. 4 (*a*), 5 (*a*) and 6 (*a*), with the roadway on the lower chords, are called "through" spans, and Figs. 4 (*b*), 5 (*b*) and 6 (*b*), with the roadway on the upper chord, are called "deck" spans. The deck span permits the use of sway bracing (see ¶ 21) between, and throughout the depth of, the two or more trusses forming the bridge, while the through span of course does not; but the use of the through span is often required, in order to give sufficient head-room for boats, floods, trains on crossing roads, etc., below the bridge. A truss, loaded on the lower chord, but too shallow for lateral bracing (see ¶ 20) between the upper chords, is called a "pony" truss (or "pony through" truss).

33. Panels. The points where the vertical web members meet the chords, in Figs. 4 and 5, are called **panel points;** and the rectangular spaces, *a n, n c. c d*, etc., Fig. 5 (*a*), between the verticals, are called panels.

34. The Warren truss, Fig. 6, has no verticals, as essential parts of it. See ¶¶ 45 and 46. Its subdivisions are called simply triangles; and a panel is a length of truss equal to the width of a triangle. A panel of either chord, however, is that portion of it between two panel points.

35. Further modifications of these designs, with more numerous panels, are shown in Figs. 7 to 10. Figs. 7 (*a*) and 8 (*a*), with verticals in tension, represent the Howe truss of Figs. 4 (*a*) and 5 (*a*), while Figs. 7 (*b*), 8 (*b*), 9 (*a*) and 9 (*b*), with diagonals in tension, represent the Pratt truss of Figs. 4 (*b*) and 5 (*b*). Figs. 10 represent the Warren truss of Fig. 6.

36. Fig. 8 (*a*) represents simply Fig. 7 (*a*), lowered so as to become a deck, instead of a through bridge; while Fig. 8 (*b*) represents Fig. 7 (*b*) converted from a deck to a through span by being carried on vertical end posts.

37. In Fig. 8 (*a*), the **vertical end posts, and the horizontal piece at each end of the loaded chord**, form no part of the truss proper. The latter simply act as beams, supporting the load during its passage from the abutment to the truss and vice versa. The end post in Fig (*a*) supports only one end of this beam, while that in Fig. (*b*) supports half the *truss*.

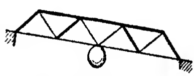
Deck Warren.



(*b*)

Fig. 10. **Through Warren.**

38. In Figs. 8 the middle vertical carries no part of the load. Theoretically it serves merely to prevent deflection of the two unloaded middle chord panels under their own weight; but in practice such members are often inserted for the purpose of obtaining convenient connections for lateral pieces, such as floor beams.

39. In Figs. 9 (modifications of Fig. 7 (*b*)) and in Fig. 10 are shown, in principle, the most common forms of metal bridge truss, used as deck and as through spans respectively.

40. In Fig 9 (*a*), as in Fig. 8, the vertical end posts and the horizontal pieces at the ends of the loaded chord form no part of the truss; and in Fig. 9 (*b*), as in Figs. 8, the middle vertical supports only the unloaded middle chord panels.

41. Intersections. In deep trusses, two or more sets of web members are sometimes combined in one truss, with one pair of chords. Thus the two simple Pratt trusses shown in Figs. 11 (*a*) and (*b*) combine to make the "Whipple" or "double intersection Pratt" truss, Fig. 11 (*c*), recently in general use.

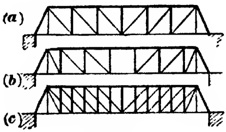


Fig. 11.

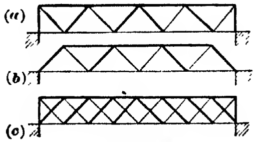

Fig. 12.

42. Similarly the two simple Warren trusses, in Figs. 12 (*a*) and (*b*), combine to form the double intersection Warren of Fig 12 (*c*).

43. A combination of *four* systems is called a "quadruple intersection" truss. See Fig 59 (*t*).

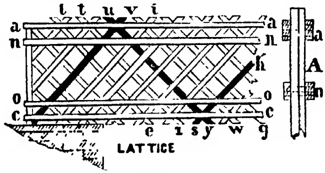

Fig. 13.

44. The old Towne "lattice" truss, Fig 13, consisting of planks crossing each other (usually at right angles) and bolted or tree-nailed together at their intersections, may be regarded as a combination of several Warren trusses.

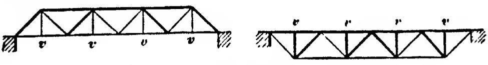

Fig. 14.

45. Sub-verticals. In deep trusses, where the horizontal spread of the panels is considerable, sub-verticals, *v*, Figs. 14 and 15, are often used, especially in Warren trusses, to support the segments of the loaded chord. See also Figs. 59 (*i*), (*r*), and (*s*).

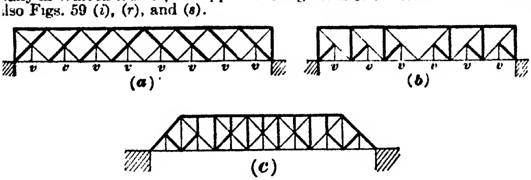

Fig. 15.

In the **"Baltimore" truss,** Fig. 15 (*b*), each diagonal is braced, at its middle point, by a short diagonal strut inclined in the opposite direction, and a sub-vertical is suspended from their junction. With very long panels, sub-verticals are sometimes used for the panels of the unloaded chord also. See Fig. 15 (*c*).

46. Collision struts, or collision posts, S, Figs. 59 (*k*), (*m*), (*o*), and (*t*), and 73 (*a*), are used for bracing long diagonal end posts against a blow from a derailed train.

Fig. 16.

47. Fink and Bollman Trusses. Figs. 16 show two obsolete modifications of Fig. 3 (*b*), viz.. the Fink, Fig. 16 (*a*), and the Bollman, Fig. 16 (*b*). The large bridge over the Ohio River at Louisville, Ky., completed 1870, is of the Fink type. The Bollman was largely used on the Baltimore and Ohio Railroad years ago.

48. In the Fink and in the Bollman truss there was but one chord, as shown. This chord usually carried the roadway. Where the roadway was placed lower, it gave the truss the appearance of having two chords. Under uniformly distributed loads, in the Fink, and under all circumstances in the Bollman, the stress in this chord was uniform throughout. In the Bollman (see Fig.), the longitudinal stresses in the chord were all applied at its ends. Each type may be regarded as a combination of several suspension trusses like Fig. 3 (*b*). In the Bollman, the simple trusses were all of the same span and depth; and each vertical post, except the central one, divided its simple truss eccentrically. The Fink principle is still largely used in metal roo trusses. See Figs. 26.

Fig. 17.

49. Curved Chords. Trusses with curved or "broken" chords, Fig. 17, are frequently used for long spans. The members themselves, between panel points, are always straight. In the **bowstring**, Fig. 17, the panel points of the upper chord lie in a curve, convex upward. In the **crescent** truss, the lower chord also is convex upward. The bowstring truss has the advantage, over those with horizontal upper chords, of making all the chord and web stresses more nearly equal, thus simplifying the construction and reducing the weight of the trusses. It has the disadvantage of permitting no overhead bracing near the ends of the span. If the curve of the upper chord is made parabolic, the dead load stress is uniform throughout the lower chord, and in each vertical (now in tension) the stress is equal to the dead load on the lower chord. The diagonals receive no dead load stress, but are called into action only by eccentric loads.

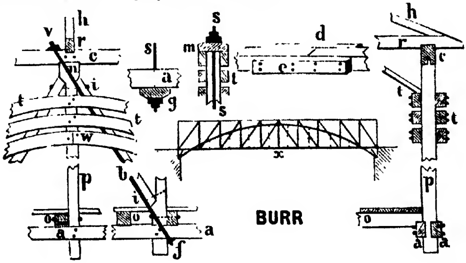

Fig. 18.

50. The Burr truss, Fig. 18, at one time much used for wooden bridges was a combination of a Howe truss and an arch.

Camber.

51. Camber. In practice, the members of the upper and lower chords of bridges are not placed perfectly in line, but so that the chords curve slightly, with the convex side upward. This curve is called the camber. Its object is to prevent the truss from bending down below a horizontal line when heavily loaded. When the chords are cambered (see *y s* and *c d*, Fig. 19),

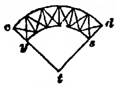

Fig. 19.

they become approximately concentric arcs of two large circles, of which the center is at *t*; and the upper one plainly becomes longer than the lower. The verticals, instead of remaining truly vertical, become portions of radii of the arcs mentioned; and, although their lengths remain unchanged, yet their tops are farther apart than their feet; and this renders it necessary to lengthen the diagonals. See ¶¶ 211–214.

Cantilevers.

52. The cantilever principle is shown in Fig 20, where A and B

Fig. 20.

represent counterweights or anchorages. Fig 21 shows the Niagara cantilever bridge. It consists of two cantilever trusses, *ab*, *a′ b′*, connected by an ordinary truss, *ba′*, which is suspended, by a vertical link at each end, from the ends of the cantilever trusses. The weight of the truss is counterbalanced by anchorages, A and B, or by weights, or both. The principal advantage of the cantilever is that it may be built outward from the piers across the channel. It thus greatly facilitates erection in cases where false-work cannot well be used.

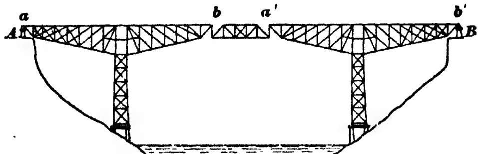

Fig. 21.

Movable Bridges.

53. Movable bridges, including draw, swing and lift bridges, are of three general classes; one in which the movable part slides horizontally, one in

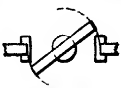

Fig. 22.

which it swings horizontally, and one in which it swings vertically. Ordinarily, the movable span is pivoted near the middle, and swings horizontally on the central "swing" or "pivot" pier, as in Fig. 22. In such cases it is

usually mounted on a central pivot, or on a nest of rollers or wheels running on a circular track. Such a bridge must be so designed that, when it is swung open, or if it is not brought to a bearing at the ends when closed, it shall sustain not only its own weight, but also any other loads that may come upon it. In addition, each half must be able to act as a bridge supported at both ends, with all possible live loads; for, as an unbalanced live load comes on either end, that end will be brought to a bearing. In elaborate bridges, provision is made for raising the ends of the draw span, when closed, thus bringing both ends to a firm bearing, and the floor flush with that on the adjacent abutment or fixed span. This raising is usually made sufficient to relieve the middle pier of only a portion of the load. The bridge then acts like a "continuous" girder (see Transverse Strength, ¶¶ 78, etc.) supported at three or at four points, depending upon the arrangement of the bearing on the pivot pier.

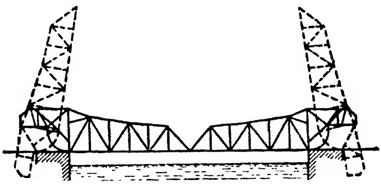

Fig. 23.

54. Drawbridges in which the movable part swings vertically (the shore end carrying a counterweight) may either revolve about a pivot, or they may roll, as in the Scherzer rolling lift bridge, Fig. 23. In the Scherzer Bridge the center of gravity of each of the two moving wings remains at a constant elevation, so that no lifting or lowering of such wing occurs, and the work done consists merely in overcoming the rolling friction of the curved end of the wing upon its support.

55. Skew bridges are used where a channel, road, etc., is crossed obliquely, and where it is inconvenient to have the abutments perpendicular to the trusses. For simplicity in making floor connections, etc., the truss is usually so designed as to bring the panel points opposite each other, as in Figs. 24 and 25. Where the skew is but slight, this necessitates a difference

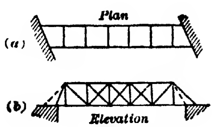

Fig. 24.

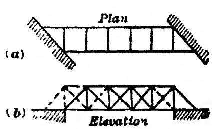

Fig. 25.

in inclination between the two end posts, as in Fig. 24, involving complication in the connections for the portal bracing. But where the skew is greater, it may be possible to make it just equal to one or more even panels, adjusting the panel length to suit, and thus leaving each truss symmetrical, as in Fig. 25. In each figure, those members which belong only to the *farther* truss (the upper one in the plan) are shown by *dotted* lines.

Roof Trusses.

56. Roof trusses are made in a great variety of forms. Those shown in Figs. 26 are common. In Fig. 26 (*a*), part of load, at *d*, compresses the rafter from *d* to *a*, while the remainder compresses the strut, *d h*, and pulls the rod *h i* and the part-chord *h a*. Similarly, part of *c* passes through *c a* to *a*, and the remainder through *c k d h i* to the apex *i*. Thus each load is eventually carried by the members, part to the apex and part along a rafter to an abutment. It will be seen that the greatest stresses in the rafters and in the chord occur near the ends.* Sometimes the members shown

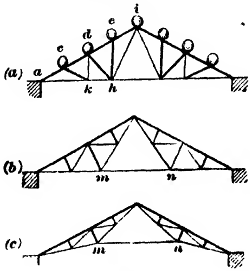

Fig. 26.

vertical in Fig. (*a*) are inclined, or the lower chord is "broken," being usually convex upward. Roof trusses are often composed, as in Figs (*b*) and (*c*), of two Fink trusses, inclined, and leaning against each other, their feet being held in position by a tie, *m n*, and the rafters forming the upper chords of the Fink trusses.

STRESSES IN TRUSS MEMBERS.

General Principles.

57. Conditions of Equilibrium. In trusses, as in beams, it is necessary and sufficient, for equilibrium, that the internal stresses, and their moments, shall balance the external forces and their moments The external forces (viz., the loads and the end reactions) and the resulting moments and shears, are discussed under Statics, ¶¶ 285, etc. We here discuss the determination of the internal stresses For the fundamental distinction between beams and trusses, see Trusses, ¶ 3.

58. In general, the stresses in the members are found by means of the principles of moments (Statics, ¶¶ 301, etc.), and of Shears (Statics, ¶¶ 325, etc.); making use of the force parallelogram (Statics, ¶¶ 35, etc) or force triangle (Statics, ¶¶ 46, etc.), the force and cord polygons (Statics, ¶¶ 72, etc., 86, etc) and the influence diagram (Statics, ¶¶ 339, etc).

59. A very convenient method, and one in common use, is that described more fully in ¶¶ 67, etc , below, where the truss is considered as being cut through by a section. We then seek to ascertain what stresses, in the members so cut, would be required to preserve equilibrium.

60. Before the stresses can be calculated, and the truss proportioned to those stresses, its weight must be known; for this constitutes a load, and therefore affects the stresses. But, on the other hand, we cannot learn its weight until we know the sizes of its different members. In this dilemma we must assume for it an approximate weight, based upon our knowledge of somewhat similar trusses already built. This becomes the more necessary as the truss increases in size, so that its own weight becomes greater in proportion to that of the load.

---

* If the diagonals were parallel, their stresses, and those in the verticals, would be greatest at the center of the span and least at the abutments.

61. To distinguish between ties and struts; from the point, o, Figs. 27, where the force is applied, draw $o\,c$ to represent the applied force, in the direction in which that force tends to move the point, o; and upon $o\,c$ as a diagonal construct the force parallelogram, $a\,b$. Through o draw $i\,i$ parallel to the other diagonal $a\,b$. Then, if a piece be on the same side of $i\,i$ with $o\,c$, it is a strut; while, if it be on the opposite side, it is a tie.

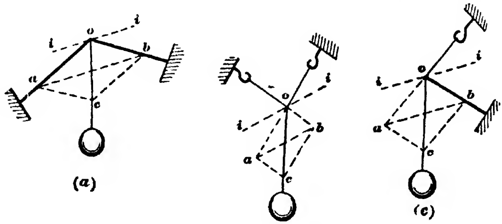

Fig. 27. (b)

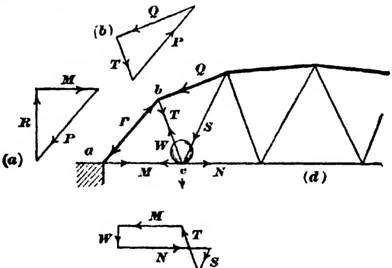
62. Ties and struts may often (as in Fig. 27) be readily distinguished by inspection, by imagining the piece to be flexible, like a rope or chain. If it is seen that it would then resist the force acting upon it, the member is a tie; if not, it is a strut. Or, suppose that the piece is not secured at its ends. If, then, it is seen that it would resist the force acting upon it, the member is a strut; if not, it is a tie.

63. Or we may proceed as follows: In Fig. 28 (a), representing joint a, we begin with the known net vertical reaction, R *; and find the unknown stresses in the chord and in the end post by means of the force triangle, making their arrows follow the known direction of R. Transferring these arrows to the respective truss members, Fig. (d), we find that the chord pulls away from a, and is therefore a tie; while the end post pushes toward a, and is therefore a strut.



(c) **Fig. 28.**

64. In Fig. (b), representing joint b, we draw P upward to represent the pressure of the end post toward b; and the other two sides of the force triangle give the pressure in the chord member, Q, and the tension in the tie, T.

65. In Fig. (c), representing joint c, we know T, M, and the load, W, and we obtain the tension, N, and pressure, S, in the corresponding members.

---

* Inasmuch as half of each end panel rests directly upon a support, and thus adds nothing to the stresses in the members, we must, in determining those stresses, use only the

net reaction = reaction — half panel load.

66. *Tensile* stresses, because they tend to *elongate* a member, are conventionally regarded as *positive*, and designated by +, while *compressive* stresses are regarded as *negative*, and designated by —.

Method by Sections.

67. Let Fig. 29 (*a*) represent a roof truss, with three equal loads, W, of 2 tons each, applied at *a*, *c* and *b*, respectively, and let it be required to find the stresses produced, by those loads alone, in the members *a c* and *a d*. Suppose the portion shown in Fig. 29 (*b*) to be separated from the rest of the truss, as shown, by cutting through the members *a c* and *a d*. The lower portions of those members, shown in (*b*), are, however, supposed to be held in their original positions by the stresses S_c and S_d, exerted in these members themselves. Taking moments about the right support, *b*, Fig. 29 (*a*) we have, for the upward reaction of the left abutment, *a*,

$$R = \frac{3\,W}{2}.$$

68. We have, then, at *a*, Fig. 29 (*b*), four forces, as follows: two known forces, viz.: W, vertically downward, = 2 tons, and R, vertically upward, $= \frac{3\,W}{2}$; and two unknown forces, S_c and S_d. Now S_c makes a known angle, A, and S_d a known angle, B, with the vertical. The vertical forces, W and R, have, of course, no horizontal resolutes (see Statics, ¶¶ 54, etc.); and their vertical resolutes are the forces themselves.

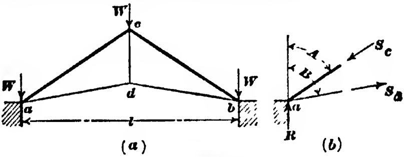


Fig. 29.

69. The horizontal resolutes of the inclined forces, S_c and S_d, are, respectively: S_c.sinA, and S_d.sinB; and their vertical resolutes are: S_c.cosin A, and S_d.cosin B.

70. We see, by inspection, that the stress, S_c, in the rafter, *a c*, is compression, and that the stress, S_d, in the lower member, is tension; but, for convenience, we may at first assume, in advance, that all of the unknown stresses are tensions or +. Then those which finally appear as + are known to be tensions, and vice versa. Their horizontal resolutes, in this case, are therefore both taken, for the present, as being right-handed, or positive; and their vertical components upward or positive also. It will be remembered (see ¶ 66) that we regard tensions as positive, and compressions as negative.

71. Now, in order that the four forces at *a*, viz.: W = 2 tons, downward, $R = \frac{3\,W}{2}$ upward, S_c and S_d, may be in equilibrium, it is necessary;

(1) that the sum of their horizontal resolutes be zero, or
S_c.sin A + S_d.sin B = 0;
(2) that the sum of the vertical resolutes be zero, or
R — W + S_c.cosin A + S_d.cosin B = 0.

Thus, let A = 45°, sin A = 0.707; cosin A = 0.707.
B = 75°, sin B = 0.966; cosin B = 0.259.

Then $0.707\,S_c + 0.966\,S_d = 0;$

$$R - W + 0.707\,S_c + 0.259\,S_d = 0;$$

$$S_c = \frac{-0.966\,S_d}{0.707} = \frac{-0.259\,S_d - R + W}{0.707}$$

$$0.966\,S_d - 0.259\,S_d = 0.707\,S_d = R - W.$$

72. Again, in Fig 30, with section $u\,v$, stress in $ed = W_1 - R = 6 - 15 = -9$. With section vy, stress in $ef = \frac{W_1 - R}{\cos\theta} = \frac{-9}{\cos\theta}$. With section ux, stress in $gd = \frac{W_1 + W_2 - R}{\cos\theta} = \frac{-3}{\cos\theta}$. It will be seen that these forces, all acting *downward* on the part truss to the *left* of the section, give *tension* in *ed*, and *compression* in *ef* and *gd*

With section *uz* we cut *two* web members, *gd*, and *gc*; but the stress in *ga* has already been found $= \frac{3}{\cos\theta}$, the vertical component of which is $= 3$. Hence, stress in $gc = W_1 + W_2 + W_3 + 3 - R = 6$.

73. It is, however, evident from inspection that the middle vertical bears simply the middle load, $W_3 = 6$, for, cutting the truss by a curved section, as at *c*, and examining the small portion thus cut out, we see that we have but two vertical forces—viz, the central load, W_3, and the stress in the vertical member; and, for equilibrium, these two must be equal.

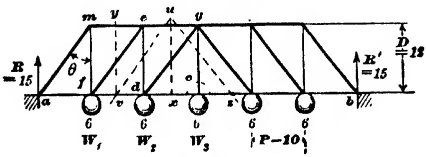

Fig. 30.

Chord Stresses, Moments.

74. For the chord stresses, Fig. 30, let P = panel length = 10 ft. Then the bending moment at the panel point, *d*, is

$$\begin{aligned} M &= 2\,R\,P - W_1\,P \\ &= 15 \times 20 - 6 \times 10 \\ &= 300 - 60 = 240. \end{aligned}$$

Cutting the truss by section $u\,v$, we find that, of the three members cut, only the upper chord member, *eg*, has a moment about *d*. Call its stress S. Its leverage is the depth, D, of the truss, = 12; and, for equilibrium, S D = M. Hence, $S = \frac{M}{D} = \frac{240}{12} = 20$.

75. Similarly, taking moments about *e*, we find the stress, in the lower chord member, *f d*, cut by the section, $u\,v$, to be $\frac{240}{12} = 20$, or the same as the stress in the upper chord panel cut by the same section. Inspection shows the correctness of this result; for the diagonal strut, *e f*, evidently delivers to the upper chord panel, *e g*, a compressive stress or "chord increment" (see ¶ 77) = the tensile stress which it delivers to the lower chord panel, *f d*.

76. If the chord members are inclined, their lever arms must of course be measured *perpendicularly to them;* and we can no longer use the vertical depth of the truss as the lever arm.

77. Chord Increments. Fig. 30. Each diag delivers a comp stress to the upper chord, and, in trusses with parallel chords, an equal tensile stress to the lower chord Find the shear, or vertical component, V_1, V_2, etc, of the stress in each diagonal, beginning with the end post. Then the "chord increments," h_1, h_2, etc, or the stresses in the chord members, *af* and *me*, *fd* and *eg*, etc., due to the several diagonals separately, are

$$\begin{aligned} h_1 &= V_1 \tan\theta \\ h_2 &= V_2 \tan\theta \\ h_3 &= V_3 \tan\theta \end{aligned}$$

and, for the *total* stress in each chord member, we have, $H_1 = h_1$ $H_2 = h_1 + h_2$; $H_3 = h_1 + h_2 + h_3$; and so on.

Shear.

78. Any portion of a shear diagram applies to all those members through which its shear travels, up to the *panel point* where the shear undergoes a change. Thus, in Fig. 31 the shear diagram on the right of the Fig. includes the vertical, *tu;* that on the left includes the diagonal, *mo;* and that between the loads includes the diagonal, *t n*, and the vertical, *m n*.

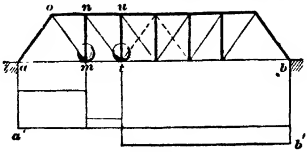

Fig. 31.

79. Shear Influence Diagram. See Statics, ¶¶ 325, etc. In a truss, Fig. 32, the ordinates, *c' g*, etc., to the line *a'' b'* (constructed as in Fig 156, Statics, ¶ 349), give the left end *reactions;* and those, *c' h*, etc., to the line *a'b''*, give the right end *reactions*, for *any position* of the load; and the resulting *shears* for a load, W (not shown), *at any panel point;* but the *shears in a panel, cd*, for a load, W, *between the panel points*, are modified by the action of the stringers in distributing the load between said adjacent panel points, as indicated by the influence lines, *gh*, etc., for the several *panels*. Thus, with W at *c* and at *d*, respectively, the shear, in the panel *cd*, is represented respectively by *c'h* (negative) and by *d'q* (positive); and, as the load passes from *c* to *d*, the shear in the panel changes from *c'h* to *d'q*.

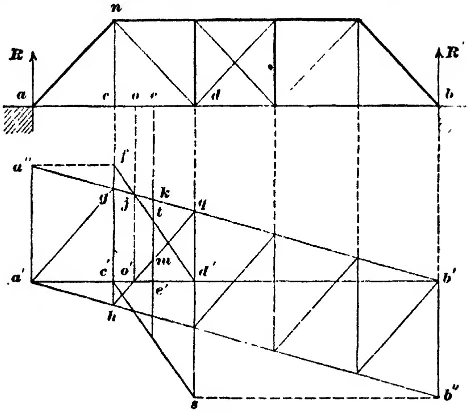

Fig. 32.

But when W is placed at any point, *e*, between *c* and *d*, its load is distributed between the panel points, *c* and *d*, by the stringer, acting as a beam.

80. Thus, drawing, for this beam, *c d* (as for the whole beam in Statics Fig. 156), the *panel* influence lines *fd'* and *c's*, we see that, as W moves from *d* into the panel *cd*, as to *e*, the truss reaction at *a* is thereby slightly increased from *d'q* to *e'k;* but at the same time a portion of W, represented by *e't*, is

carried by the stringer to c, where it diminishes the shear $e'k$ (due to the truss reaction at a), leaving tk as the value of the shear in the panel. As we place W successively at other points, farther from d, and approaching o, the load carried by the stringer to c, and represented by the ordinates from $c'd'$ to fd', continue to increase faster than does the left end truss reaction, R, represented by the ordinates from $a'b'$ to $a''b'$; and the resulting shears in the panel are represented by the ordinates from jd' to jq. At o, the part load, $o'j$, carried to c, is = the left truss reaction, and the shear in the panel is zero. With the load between o and c, the part loads carried to c, and represented by the ordinates from o' c', to jf, are *greater* than the corresponding left end truss reactions; and the result is a *negative* shear in the panel, indicated by the ordinates from j g to jf. It will be noticed that the resulting shears throughout, both positive and negative, are indicated by the ordinates from $c'd'$ to hq.*

Reversing the process, a similar argument may be applied to the panel influence line $c's$, beginning with the load at c, with negative shear in panel = $c'h$, and supposing it moved across the panel to d, where positive shear in the panel becomes = $d'q$.

81. In the case of a **uniform load,** extending on to the span from the right support, b, the point o is the position of head of load for maximum positive shear in the panel, cd; for, in the case of a uniform load, the shear, with head of load at e, is represented by the *area* (sum of all the ordinates) $e'mqb'e'$; and manifestly this area increases as the head of the load approaches o; but when it reaches o, the area above $a'b'$ can increase no further, and when it *passes* o, the *negative* shears, represented by the ordinates from $o'c'$ to $o'h$, begin to *reduce* the resultant positive shear.

82. Having found, by any method, the maximum shear, $d'q$, due to a concentrated load at d, for the diagonal, d n, Fig. 32, and the reverse maximum shear, c' h, due to the same load at c, we may draw an influence line, h q, which gives, as before, the point, o, of position of head of uniform load for maximum stress in the diagonal, d n, from which (as above) we find the corresponding position of the head of a series of concentrated loads.

In practice, the influence line for shear is of value chiefly in thus finding the position of load producing maximum stress, and the resulting stresses, in trusses with *curved* chords, such as Fig. 17. In such a truss, owing to the inclination of the members of the upper chord, those members take some of the shears in their respective panels, and the stress in the diagonal is therefore less than the shear in the panel.

Graphic Determination of Dead Load Stresses.

83. Construct first a diagram of the truss, as in Fig. 33 (a), lettering the spaces between the members, and those between the arrows representing the dead loads. Call the end post, 1–3, between A and B, "AB," the stress in it "ab," the load at 2, "cd," etc., using capital letters for panels and truss members, and small letters for loads and stresses. Adopt a suitable scale of forces, and construct the diagram, Fig. 33 (b), as follows:

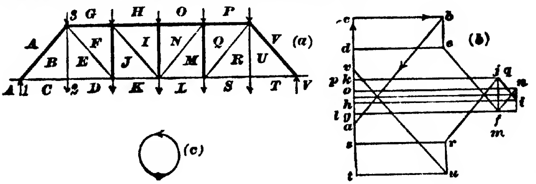

Fig. 33.

84. Consider first the point 1, Fig. 33 (a). There are here three forces in equilibrium, viz., ac, ab and bc. Find the net end reaction, R = ac, and lay it off upward (since it acts upward on 1) from any convenient point, a, to c, Fig. 33 (b). From a draw an indefinite line ab parallel to AB and from c

* Since fh, jo', qd' and ke' are parallel, me' = kt, and $c'h$ = gf.

draw cb parallel to BC, obtaining the force triangle acb of the point 1. The lengths of cb and ba then give the stresses by scale.

85. In Fig. 33 (b), the arrow on ac indicates the upward direction of that force. Following around the triangle, we affix arrows (in the same direction) to cb and ba. Supposing these arrows now to be transferred to the corresponding members in Fig. 33 (a) we see that $b\,c$ pulls from the point 1, showing that $b\,c$ is tensile, or +, while $b\,a$ pushes toward 1, showing that $b\,a$ is compressive, or —.

86. The characters of the stresses may be found more quickly as follows: Draw a circle, Fig. 33 (c), and place on it arrows pointing around in the direction (counter-clockwise in this case) followed around the truss in constructing the load line. See ¶ 92, below. Then consider any panel point, Fig. 33 (a), and follow the letters in the spaces around that point in the direction of the arrows on the circle. Note the order of the letters, and follow the corresponding equilibrium polygon, Fig. 33 (b), around in the same direction. This will give the directions in which the forces respectively act on that point.

87. Thus, consider the panel point 2. Following around 2 in the direction of the circle, we read B, C, D, E. Turning now to Fig. 33 (b), and reading b, c, d, e, we find that on bc we go from right to left (or opposite to the direction indicated by the arrow drawn for point 1); hence bc acts to the left on 2, and BC is therefore in tension, and its stress bc is +.

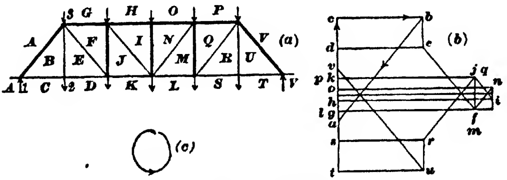

Fig. 33 (repeated).

88. Given now the stress, bc, in BC, construct, on bc, the force polygon $bcde$ for the four forces acting on the point 2. Thus, from c lay off cd downward, to represent the dead load on the lower chord at 2. Since bc acts as a pull from the left on 2, and since the forces must follow each other around the polygon, cd must evidently be drawn downward from c and not from b. From d draw an indefinite line parallel to DE, and from b another, parallel to BE. They will intersect at some point, as e, and eb and de will then represent the stresses in BE and DE.

89. Inspection would show that $be = cd$, since cd is the only force acting on 2 with a vertical component, and that $bc = de$; but the construction of the force polygon $bcde$ is necessary for the completion of the diagram.

90. Having now found the stresses in DE, BE, and AB, and knowing the panel load ($= g\,a$) at the point 3, construct the polygon $g\,a\,b\,e\,f\,g$. This gives $e\,f$ and $f\,g$, and from these the process may be continued and the diagram completed.

91. It will be noticed that, in some cases, a point on the diagram, Fig. 33 (b), is given more than one letter. Ordinarily this is simply a coincidence, arising from overlapping of the force polygons. In some cases, however, the coincidence of the letters shows that the stress in the member is zero.

92. In practice it is usual to construct first the entire load line ct, thus. draw first the net reaction, ac, upward; then, following around the truss counter-clockwise, draw all the other exterior (dead load) forces in their proper order, thus cd, dk, kl, ls, st, tv, vp, po, oh, hg, ga. The stress diagram may then be constructed, as before.

Live Loads.

93. It might at first be supposed that each member of the truss would receive its maximum stress when the train completely covered the bridge; but this is true only of the chord members. In the truss shown in Fig. 33 (*a*) each web member receives its maximum stress when the greatest possible shear occurs in a section cutting that member.

Fig. 34.

94. In Fig. 34, the *main* diagonals to the *left*, and the *counters* to the *right* of the center, C, are shown. Any one of these members receives its maximum stress from a uniformly distributed load when the load extends from it to the *right* support *b*, with head of load at a point, *o*, Fig. 32 (*a*), found as in ¶ 81; and *vice versa* for the diagonals inclined in the *opposite* direction. Each *vertical* receives its maximum stress when the load extends from the *farther* support to a point, *o* (see ¶ 81), in the panel beyond the vertical. This statement must be slightly modified when the concentrated wheel loads are considered. See ¶¶ 97, etc.

Fig. 35.

95. Assumed Uniform Live Load. As a crude approximation, the engine and train are sometimes considered as a uniform load crossing the bridge, Fig. 35; but this method, ignoring, as it does, the great concentration of weight in modern locomotives, is apt to be either unsafe or wasteful of material. This assumption is proper in connection with wind pressure on train. See ¶ 121.

Fig. 36.

96. Concentrated Excess Loads. Again, to provide for the locomotive loads, one or more concentrated excess loads, Fig. 36, are sometimes employed. The stresses due to these loads may be computed separately, and added to the stresses produced by the uniform live loads. To produce the maximum chord stresses, the excess loads should be in the middle of the span, and the train load should cover the entire bridge. This method is fairly approximate, and engineers are divided as to whether this method of concentrated excess loads should be used, or that of the actual or "typical" locomotive wheel loads as explained below.

97. Standard or Typical "Wheel" Loadings. In the method of wheel loads, the actual stresses, produced by the heaviest engines likely to cross the bridge, are considered. Even in engines of nearly the same weight, the loads may be differently spaced, and spaced at intervals of odd fractions of an inch, rendering computation very laborious. For this reason, and in order to provide for the use of heavier engines in the future, it is customary to consider an imaginary or "typical" engine, with loads and spacing given in round numbers, the stresses from which shall at least be equal to those produced by the heaviest engines likely to be used during the life of the bridge.

The live loads are ordinarily taken as consisting of two typical locomotives with their tenders, followed by a uniform train load. See Digests of Specifications.

98. The following is an example of the computation of live load stresses by the method of locomotive wheel loads:

Fig. 37 (*b*) represents the loads on one rail, corresponding to Cooper's Standard,* Class E 40, which consists of two coupled consolidation locomotives, followed by a train considered as equivalent to a uniform load of 4000 lbs. per linear foot. In the diagram, Fig. 37 (*a*), all loads are figured in thousands of pounds, moments in millions of foot-pounds, and distances in feet.

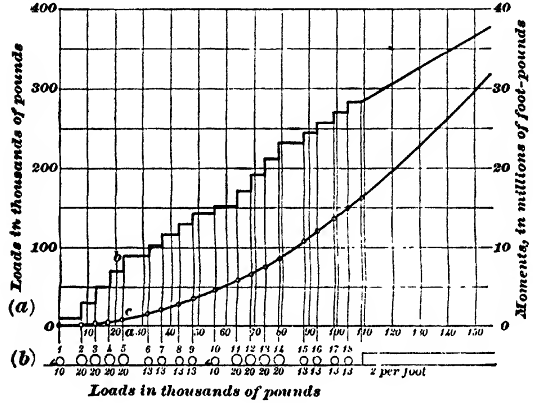

Fig. 37.

99. Live Load Web Stresses. The maximum live load stresses will occur in the web members of any panel of the truss in Fig. 34 or 38, when the live load produces the maximum shear in that panel. It can be shown that this will occur when $P = \frac{W}{n}$, where P = the live load on the panel cut by the section; W = the total live load on the truss, and n = the number of panels in the truss. This equation is called the criterion for maximum shear.

100. The following table is based upon this relation. The second column is obtained by adding successive wheel loads to P. In this case, W = 6 P, since our truss has 6 panels. Let any wheel be at a panel point Then, by moving the wheel a little to the left or right, it will be included in or excluded from P. Hence P and W have each a minimum and a maximum value for each wheel at the panel point.

No. of wheel at any given panel point.	Value, P, of load on panel to left of given point.	Corresponding value of W for maximum shear in panel.
1	0 to 10,000	0 to 60,000
2	10,000 to 30,000	60,000 to 180,000
3	30,000 to 50,000	180,000 to 300,000
4	50,000 to 70,000	300,000 to 420,000
5	70,000 to 90,000	420,000 to 540,000

101. The correct position of live load, for maximum shear in any panel, is found by successive trials. When the correct position is found, the

* "Transactions Am. Soc. Civ. Engrs.," vol. XLII, No. 858. Dec., 1899, p. 227. See Digests of Specifications.

moment about the right support is computed, and from this the shear is obtained. For example, see below.

102. These operations may be performed by computation, with or without the aid of graphic methods. As the method of computation alone is rather tedious, particularly when the form of the truss is complicated by curved chords or sub-panels, and as the graphic method is abundantly accurate for all practical purposes, and has the advantage of direct appeal to the eye, only the latter is given herewith.

103. The "wheel diagram," Fig. 37 (*a*),* gives (1) a stepped "load line" or "shear diagram," and (2) a curved "moment diagram" or "equilibrium polygon." See Statics, ¶¶ 359, etc.

104. The load line gives the total live load to the left of, and including, any point.

105. The moment line gives, at any point, the (left-handed) live load moment, about that point, of all loads to the left of and including that point. Thus, to the left of and including wheel No. 5 we have

Wheel.	Load.	Distance from wheel 5.	Moment about 5 in ft.-lbs.
1	10,000	23	230,000
2	20,000	15	300,000
3	20,000	10	200,000
4	20,000	5	100,000
5	20,000	0	0
Total,	90,000		830,000

and the ordinates, *ab* to the load curve, and *ac* to the moment curve under wheel 5, measure 90.0 and 0.830 respectively.

106. Fig. 38 represents the truss, to the same scale as Fig. 37. We may call this a "truss diagram." †

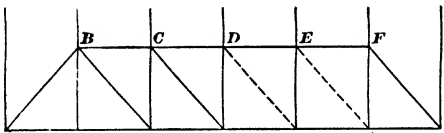

Fig. 38.

107. Example. To compute the maximum shear in the panel *bc*, Fig. 38, first find that position of the load which will produce that maximum shear. As a guess, place the truss diagram, Fig. 38,† with its point *c* under wheel 2, Fig. 37. Examining the load diagram, over the right end, *g*, of the span, we see that we now have a total load, W, of 284,000 lbs. on the span; and the load diagram, over wheel 2 (placed at point *c*) shows (see also table, ¶ 100) that the load, P, on the panel, *b c*, is now somewhere between 10,000 and 30,000 lbs.; but, for maximum shear in the panel, *b c*, the load, P, on that panel must be (see ¶¶ 99 and 100) $= W \div n =$ $284{,}000 \div 6 > 30{,}000$ lbs. Hence, P must be increased by moving the train diagram, Fig. 37, to the left (or, which is the same thing, by moving the truss diagram, Fig. 38, to the right) until wheel 3 is over *c*. We now have W = 292,000 lbs.; P = anywhere between 30,000 and 50,000; and required value of P, for maximum shear, $= W \div n = 292{,}000 \div 6 =$ 48,667 lbs. Hence, the conditions are satisfied, and panel *b c* receives its

* Method published by Ward Baldwin, "Engineering News," vol. XXII Sept. 28, 1889, p. 295. See also letter, "Eng. News," Dec. 28, 1889, p. 615

† For the following discussion it will be found convenient to make a copy of Fig. 38, or simply of the lower chord, on a separate piece of paper which may be applied, in different positions, to Fig. 37.

maximum shear, when wheel 3 is at c. The moment diagram shows, vertically over g, the live load moment about the right support = 17,516,000 ft.-lbs.; and the moment at c = 233,000 ft.-lbs.

108. Let M = the (left-handed) live load moment at the right abutment, due to all the loads on the span

L = the span.

m = the (left-handed) live load moment at the panel point on the right of the panel in question

l = the length of the panel.

V = the shear in the panel.

$$\text{Then } V = \frac{M}{L} - \frac{m}{l} = \frac{17{,}516{,}000}{150} - \frac{230{,}000}{25} = 107{,}600 \text{ lbs}^{*}$$

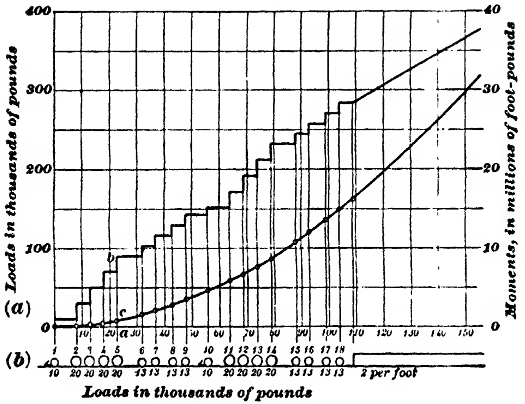

Fig. 37 (repeated).

109. The maximum live load shears in the other panels, similarly computed, are as follows, the load being, in each case, so placed as to give said maximum shear:

Panel, No and Position of Wheel.	Mom M at Rt End of Truss Ft.-lbs.	Mom m at Rt. End of Panel. Ft.-lbs.	Shear, Pounds. $V = \frac{M}{L} - \frac{m}{l}$	Member.	Stress, Pounds. $S = \frac{V}{\cos\theta}$†
ab 4 at *b*	27,176,000	480,000	162,000	*a*B	−217,200
bc 3 at *c*	17,516,000	230,000	107,600	B*c*	+144,200
cd 3 at *d*	10,816,000	230,000	63,000	C*c*	−63,000
				C*d*	+84,500
de 2 at *e*	4,936,000	80,000	29,700	D*d*	−29,700
				D*e*	+39,800
ef 2 at *f*	1,743,000	80,000	8,400	E*f*	+11,250

* Because $\frac{M}{L}$ = the reaction of the left support, a, and $\frac{m}{l}$ = so much of the panel load as goes to the left end of the panel.

† θ = angle between diagonal and vertical.

110. The live load stress in the hip suspender, Bb, is due entirely to loads upon the two lower-chord panels, *a b* and *b c*. Thus, with wheel 4 at *b*, panel length = *a b* – *b c* = 25 ft., we have:

On *a b*				On *b c*			
Wheel.	Load, W.	Dist, *d*, from *a*.	Stress on B*b* = *wd* ÷ 25.	Wheel.	Load, W.	Dist, *d*, from *c*.	Stress on B*b* = *wd* ÷ 25.
1	10,000	7	2,800	5	20,000	20	16,000
2	20,000	15	12,000	6	13,000	11	5,720
3	20,000	20	16,000	7	13,000	6	3,120
Total,	50,000		30,800	Total;	46,000		24,840

Total load on *a b*	50,000	Stress in B *b* from *ab*	= 30,800
" " " *b c* =	46,000	" " " " *b c*	= 24,840
Wheel 4 =	20,000	" " " " wheel 4	= 20,000
Total load on *ac* =	116,000	" " " Total,	75,640

111. For any given set of loads on *a c*, the *maximum* stress in B *b* occurs when the load on *a c* is *equally* divided between *a b* and *b c;* and this ordinarily occurs while some wheel (to be found by trial) is passing *b*. Thus, with wheel 4 just to the *right* of *b*, we have, on *a b*, wheels 1, 2 and 3, = 50,000; and, on *b c*, wheels 4, 5, 6 and 7, = 66,000 lbs.; but, with wheel 4 just to the *left* of *b*, we have, on *a b*, wheels 1, 2, 3 and 4, = 70,000; and, on *b c* (neglecting wheel 8, which now enters *b c*), wheels 5, 6 and 7, = 46,000 lbs. Hence, while wheel 4 is passing *b*, there is an instant when the loads on *a b* and on *b c* are equal, and at that instant the stress in B *b* reaches its maximum (75,640 lbs., see ¶ 110) for the given set of loads.

112. Live Load Chord Stresses. The criterion, for position of load for maximum bending moment in any section, and hence for maximum stress in the chord members at that section, is $\frac{W}{w} = \frac{L}{l}$, or $l = L.\frac{w}{W}$; where W = total load on the truss, w = load to the left of the section, L = span of bridge, and l = length of segment to the left of the section.

113. To find the position of load for maximum moment in any panel, by means of the moment diagram, Fig. 37; place a wheel, say wheel 2, at the panel point at the right of the given panel. From the intersection on the load line (usually coinciding with the x-axis) vertically over the left support, lay a ruler or stretch a thread to the intersection of the load line with a vertical from the right support. If the line so constructed recrosses the load line at a point vertically over the section in question, the position is a correct one; if not, it is incorrect. To facilitate this work, it is well to use a truss diagram, Fig. 38, drawn on a sheet of tracing paper, with the verticals carefully extended from the panel points as far up as the load or moment lines are likely to extend.

114. It will often be found that more than one position satisfies the criterion, and that some one of these may give greater moments than the others Hence it is well to look for all possible positions. When these are found, determine the moments, thus: On the moment curve find the two points corresponding (vertically) with the left and the right support respectively, and join these points by a straight line. When the head of train has not reached the left support, the point corresponding with the left support is in the x-axis, produced.

115. The required moment is measured by the vertical ordinate distance along the section, between the moment curve and the straight line just constructed. The stress in the chord members affected is equal to the moment divided by the depth or the truss. Using these methods, the following results are obtained:

Section.	Wheel.	Moment, ft.-lbs.	Stress, lbs.	Members.
B*b*	4	4,049,333	144,600	*ab* = *bc*
C*c*	7	6,211,667	221,800	*cd* = —BC
C*c*	8	6,207,667	Not max.	
D*d*	11	7,044,000	Not max.	
D*d*	12	7,056,500	252,000.	—CD = —DE

Wind Loads.

116. A complete bridge is subjected not only to *vertical* loads, due to dead load, to live load, and to impact caused by inequalities in track and in rolling stock, but also to *horizontal* loads. These horizontal loads are due to the transverse action of wind, or of centrifugal forces produced by the train in passing around a curve on the bridge, and to the longitudinal traction or "drag" caused by stopping or starting a train on the bridge. Hence it is necessary to supply horizontal bracing, which, with the two upper chords or the two lower chords of the two vertical trusses, form horizontal trusses, known as the upper and lower lateral systems, Figs 39 (*a*) and 39 (*b*), and sway and portal bracing, ¶¶ 21 and 22.

117. The wind is considered as blowing at right angles to the bridge.

118. The wind produces several effects, and these must be ascertained separately, and their joint effect then determined. Among these effects are:

(1) Direct stresses in both the upper and lower lateral systems, by pressing directly upon the chords; acting horizontally as a uniformly distributed load.

(2) Additional direct stresses on the lateral system of the loaded chord when a train is on the bridge, owing to pressure of wind against the train.

(3) An overturning moment upon the bridge as a whole, thus increasing the dead and live load stresses in the leeward and diminishing those in the windward vertical truss.

(4) A similar overturning effect upon the train and its wheels, which similarly modifies their pressures upon the floor beams and thus the stresses in the main trusses.

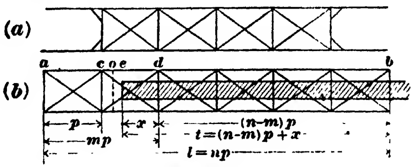

Fig. 39.

119. The wind load, acting directly upon the bridge, is assumed to be equally divided between the upper and lower chords, and between the windward and leeward trusses

120. (1) The direct wind stresses in the lateral bracing, due to the pressure of the wind on the truss, are found as are the stresses in the main trusses, due to dead load; the horizontal transverse struts of the lateral bracing corresponding to the verticals of the main trusses.

121. (2) Direct stresses in lateral system of loaded chords, Fig. 39 (*b*), due to wind on train.

Examining any panel, as $c\,d$, let

w = wind pressure, in lbs. per lineal foot of train;
p = panel length, in feet;
$w\,p$ = wind pressure, in lbs., per panel fully occupied by train;
n = number of panels in span (= 6 in this case);
l = $n\,p$ = span, in feet;
m = number of panels from left support, a, to and including the panel, $c\,d$, under consideration;
$m\,p$ = distance, $a\,d$, in feet;
x = length, in feet, of that portion of the panel, $c\,d$, which is occupied by train;
t = $(n - m)\,p + x$ = that portion of the span which is occupied by train, in feet;
= wind pressure on train for a pressure of 1 lb. per lineal foot;
R = truss wind reaction,* at a, = $w\,t^2 \div 2\,l$;
r = panel wind reaction,* at c, = $w\,x^2 \div 2\,p$;
S = wind shear * in panel, $c\,d$, = $R - r = w\,t^2 \div 2\,l - w\,x^2 \div 2\,p$.

---

* See foot-note (†), ¶ 2.

The horizontal *truss* reaction,* at a, due to a concentrated horizontal pressure, $= 1$, acting at any distance, y (not shown), from d, is $= \frac{(n-m)\,p+y}{n\,p}$; and the horizontal *panel* reaction, at c, due to the same pressure, is $= \frac{y}{p}$. The maximum wind shear,* in the panel, $c\,d$, due to wind on train, occurs (see ¶¶ 79 to 81) when the head of the train reaches that point, o, at which, if the concentrated load be placed, these two reactions will be equal, or $\frac{y}{p} = \frac{(n-m)\,p+y}{n\,p}$. With head of train at o, we have $x = y = \frac{(n-m)\,p}{n-1}$.

Under any conditions, the wind shear,* S, in the panel, is $= R - r$, where $R = \frac{w[(n-m)\,p+x]^2}{2\,n\,p}$; and $r = \frac{x^2}{2\,p}$.

Substituting here the value of x, just found, for maximum shear, we obtain, as the maximum value of the wind shear* in the panel,

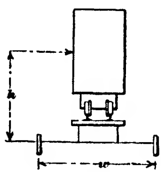
$$S_{max} = \frac{w\,p}{2\,(n-1)}\,(n-m)^2.$$

122. (3) Stresses in main truss members, due to overturning moment of wind on truss.

Overturning moment = (wind panel load at top chord) × (number of panel points in span) × height of truss.

$$\text{Vertical reaction at one support} = \frac{1}{2}\,\frac{\text{overturning moment}}{\text{width between trusses}}.$$

Since the upper lateral system carries all wind loads to the ends of the bridge, the end posts and the chords (which take the horizontal components of the end post thrusts) are the only main truss members affected.



(a)

Fig. 40.

123. (4) Stress in main truss members, due to overturning moment of wind on train, Fig. 40. Let h = height from center of gravity of lateral system of loaded chord to center of pressure of wind on train, p = wind pressure per lineal foot of train, w = width between centers of gravity of trusses, m = overturning moment, per lineal foot of train, v = added vertical load on leeward truss, per lineal foot of truss. Then $m = h\,p$, and $v = \frac{m}{w}$.

Impact, Etc.

124. The effects of impact, due to inequalities of the track; those of "drag," due to the starting and stopping of trains; and those of centrifugal force of the train on curves, are not susceptible of rigorous calculation, and engineers differ in their requirements respecting provision for them See Digests of Specifications.

---

* See foot-note (†), ¶ 2.

Determination of Maximum and Minimum Stresses.

125. Where specifications make allowable unit stresses depend upon the relation between the maximum and minimum stresses in any given member, both must be computed

In computing the maximum and the minimum stress in any member, bear in mind that a condition which, of itself, would have a certain effect upon the stress, may bring with it other conditions which produce a greater effect of the opposite kind. Thus, although the action of wind on train would, of itself, reduce the stresses in certain members, this action can take place only with train on bridge, and the vertical action of the train load would ordinarily increase those stresses more than the wind action would diminish them.

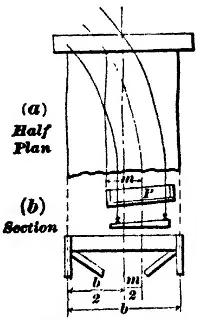
In computing minimum stresses, although the live load is usually to be neglected, we must of course not neglect the dead load, which is always present.

Curves on Bridges.

126. When the track on a bridge is curved, it is usually so laid that the center line of the bridge bisects the middle ordinate, m, of the curve. See Fig. 40 (a). The center of gravity of a panel load, P, at the center of the span (supposing it to stand over the center of the track) is thus thrown out a distance $= \frac{1}{2}\,m$ from the center line of the bridge, or a distance $= \frac{1}{2}\,b + \frac{1}{2}\,m$ from the inner truss, where b = width of bridge between centers of trusses. Taking moments about the center of the inner truss, we have, therefore, for the load, W, on the outer truss, due to P,

$$W = P\,\frac{\frac{1}{2}\,b + \frac{1}{2}\,m}{b} = P\,\frac{b + m}{2\,b}.$$

It is customary (see Digests of Specifications) to proportion the outer truss on the safe assumption that its share of the live load, at each panel point, is determined by the formula just given, and to design the inner truss like the outer one.



Figs. 40 (a) and (b).

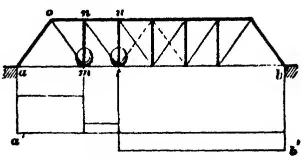


Fig. 31 (repeated).

Counterbracing.

127. In a truss of any ordinary form (like that in Fig. 31), under the action of a uniformly distributed dead or live load, or of a live load distributed symmetrically as regards the center of the span, the shears in each panel on the *left* of the center of the span are *positive*, while those in the panels on the right are *negative;* and the stresses throughout the truss are such that the ties sustain tension, and the struts, compression; the tendency, in each panel, being to *elongate* that diagonal occupied by a *tie*, and to *shorten* that diagonal occupied by a *strut*.

But the tendency of an *eccentric* load, such as those shown in Fig. 31, is to *reverse* the shears in the panels between it and the center; and, if this effort, relatively to the other forces is of sufficient magnitude to reverse the

final shear in any panel, the tendency will be to *shorten* the diagonal occupied by a *tie*, see Fig. 1 (*a*), and to *lengthen* any diagonal occupied by a *strut*.

As explained in ¶¶ 14 and 15, this condition is met, in the Warren or triangular truss, by making each web member capable of resisting both tension and compression; and, in trusses with both vertical and diagonal web members, by inserting counters.

In a drawbridge or swing bridge, not only the web stresses, but also the chord stresses, are reversed when the draw is opened or closed.

To provide against possible further increase in live loads, over those now in use, specifications sometimes require that, wherever the live and dead load stresses are of opposite character, only 70 per cent. of the dead load stress shall be considered as effective in counteracting the live load stress. For other methods of making similar provision, see Digest of Specifications for Steel Railroad Bridges.

Roof Trusses.

128. In roof trusses, **the dead load,** *i. e.*, the weight of the truss itself and that of the purlins, roof covering, etc., and the snow load, are usually taken as uniformly distributed. In many cases the sum of the dead and snow loads is divided equally between the two supports. In other words, the end reactions are equal.

129. The weights of steel trusses, in pounds per square foot of building space covered, may be taken, for preliminary estimate, at (0.05 to 0.08) × span in feet, according to design and loading. Those of **wooden trusses,** with wooden, iron or steel tension members, may be taken at from one-tenth to one-fifth less.

If it is found that the weight of a truss, as designed, considerably exceeds the weight assumed for it in advance, it should be redesigned, assuming a new weight slightly greater than that obtained from the design.

130. The weights of purlins, of steel or wood, may be taken at from 2 to 3 lbs. per square foot of building space covered.

131. The weight of roof covering may be taken approximately as follows:

Corrugated iron,	2 to 3	lbs. per sq. ft. of roof surface.
Slate,	7 to 9	" " " "
Shingles, on laths,	2 to 3	" " " "
If on boards, add	3	" " " "
If plastered below the rafters, add,	6	" " " "

132. The snow load, in States north of lat. 35°, may be taken as varying (chiefly with latitude) from 10 to 30 lbs. per sq. ft. of horizontal projection of roof surface.

133. The purlins, stringers, etc., should be so arranged as to carry the weight of roof covering and of snow directly to the panel points, and thus avoid transverse stresses in the rafters.

134. Each truss bears, besides its own weight, half the weight of roof and snow between the two trusses (or truss and wall), adjacent to it, and each panel point bears half the load between two panel points (or panel point and end support) adjacent to it.

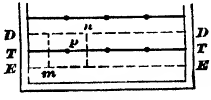

Fig. 41.

Thus, Fig. 41, truss TT carries a weight = that on the surface between the two dotted lines, DD and EE; and panel point *p* carries a weight = that on the rectangle *mn*.

135. The wind is regarded as blowing horizontally upon one side of the roof and as exerting a uniformly distributed normal pressure upon that side. In the following table of assumed normal pressures against sloping surfaces, under horizontal wind pressures of 40 lbs. per sq. ft., the values in the last column are based upon Hutton's experiments. Here *a* is the angle between the sloping roof surface and a horizontal plane.

Assumed normal wind pressure, P, in lbs. per sq. ft. Horizontal wind pressure = 40 lbs. per sq. ft. a = angle between roof surface and horizontal plane.

a.	sin a.	P 40.sin a.	P Hutton.	a.	sin a.	P 40 sin a.	P Hutton.
5°	0.087	3.5	5.1	35°	0.574	22.9	30 1
10°	0.174	7.0	9.6	40°	0.643	25 7	33.3
15°	0 259	10.4	14.2	45°	0.707	28.3	36.0
20°	0.342	13.7	18.4	50°	0.766	30.6	38 1
25°	0.423	16.9	22.6	55°	0 819	32.8	39 4
30°	0.500	20.0	26.5	60°	0 866	34.6	40 0

136. The directions and amounts of the end reactions and of the stresses in the members, due to wind, depend upon whether one or both supports are fixed. If both ends are fixed, their reactions are parallel to the normal wind pressure—*i. e.*, they are at right angles to that side of the roof upon which the wind is blowing; but, if one end is free to slide longitudinally of the truss, its reaction is taken as vertical and that of the other is more nearly horizontal than the normal wind pressure. When one end is free, the stresses must be determined for wind blowing on the fixed side (in which case it tends to flatten the roof) and also for wind blowing on the free side, in which case its horizontal component tends to shorten the tie-rod and to raise the apex. The stresses in the members of roof trusses are conveniently found by means of the method by sections, ¶¶ 67, etc., or graphically, as below.

137. Fig. 42 (a) illustrates the graphic treatment of wind stresses for Fig. 42 (b), under the three conditions named, viz :—case 1, with both ends fixed; case 2, wind blowing against the fixed side; and case 3, wind blowing against the free side *

In Fig. 42 (a), the segments ab, bc, cd and de represent the normal wind pressures at the panel points AB, BC, CD and DE respectively, and ae therefore represents the total normal wind pressure on the roof, all being exerted against the left side.*

138. In case 1 (both ends fixed) the segments fa and ef of the solid line ea represent the left and right reactions respectively.

139. In case 2 (wind blowing against fixed side) the reactions are represented by the dash line $ef'a$; and in case 3 (wind blowing against free side) by the dash-and-dot line $ef''a$.

140. The segments $f'f$ and ff'' represent the horizontal components of the right and left wind reactions respectively in case 1; and $f'f''$ that of the wind reaction of the fixed end in case 2 or case 3, or that of the total wind reaction.

141. Having found, by moments, the end reactions ef and fa for case 1; where, Fig. 42 (b),

$$ef = ae \frac{A\,s}{\text{Span}};$$

the vertical reactions, ef' and af'', for cases 2 and 3 respectively, are found by dropping perpendiculars from e and from a, Fig. 42 (a), upon gf produced. The reactions of the fixed ends are then given by the closing line, $f'a$, in case 2, and by ef'' in case 3.

* To avoid the necessity of showing two skeleton figures and two diagrams, we have supposed the wind to blow always in one direction (viz , against the left side) and first one end of the truss and then the other end to be fixed. In practice, of course, the reverse of this is the case; *i. e.*, one end or the other of the truss (if not both) is fixed, and remains so; and the wind may blow against either side. The figure and diagram will, however, answer for this latter condition also. Thus, if the wind blow against the left side, as shown, and if, as in case 2, that side is fixed, then the diagram, using the broken lines, $e\,f'\,a$, gives the stresses in the members, as they are lettered. But now (the left end remaining fixed) suppose the wind to blow against the free side; *i. e*, from the right. We may nevertheless suppose the right end fixed, and the wind blowing against the left side, as in Fig. (b), and find the stresses in the members from Fig. (a) as it stands, using the dash-and-dot diagram, $e\,f''\,a$; but we must then remember that the stresses thus found for BG, GF, etc., on the left of the truss, Fig. (b), really apply to the corresponding members, QE, QF, etc., on the right, and vice versa

142. The stresses in the web members, GH, MN, etc., Fig. (*b*), and those in the several members, BG, EM, etc., of the rafters, are given by the corresponding lines, *gh*, *mn*, *bg*, *em*, etc., in the diagram, Fig. (*a*).

143. In the leeward rafter, in this case, the stress in the three segments, ME, PE, QE, is uniform throughout, and moreover it is the same in each of the three cases, being = *me* = *pe* = *qe*.

In the four web members, LM, MN, NP, PQ, to the leeward of the center the stress, in this case, is zero, being represented by the point, *lmnpq*, Fig (*a*).

144. The stresses in the several segments, GF, JF, LF, NF, and QF, of the horizontal tie rod, Fig. (*b*), are represented, in Fig (*a*),

in case 1 (both ends fixed) by *gf*, *jf*, *lf*, *nf* and *qf*;
in case 2 (wind against fixed side) by *gf'*, *jf'*, etc.;
in case 3 (wind against free side) by *gf"*, *jf"*, etc

In each of the three cases there is uniform tension in the three leewar

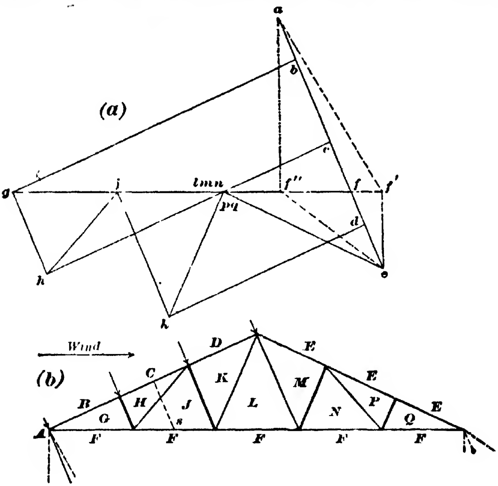

Fig. 42.

segments, LF, NF and QF, of the horizontal tie rod. This uniform tension is

in case 1 (both ends fixed) = *lf* = *mf* = *nf*;
in case 2 (wind against fixed side) = *lf'* = *mf'* = *nf'*;
in case 3 (wind against free side) = *lf"* = *mf"* = *nf"*.

145. It is thus seen that, in our Fig., with horizontal tie rod, the difference in the manner of supporting the ends affects only the horizontal stresses in the members of that rod, and, through them, the manner in which the horizontal component *f'f"* of the wind stress is distributed between the two supports.

146. If the lower chord were not straight, however, the stresses in the rafter and web members would be affected by the difference between the three cases.

147. The final or resultant stress, in any member, is the algebraic sum of the dead, snow and wind loads for that member. In some cases, the wind load may diminish or even reverse the stresses due to dead and snow loads.

148. In timber roof trusses of short span, Figs. 43 to 47, for roofs of dwellings and other small buildings, we may, with sufficient accuracy, make a liberal assumption for load, to include wind pressure. In discussing these figures, we investigate the stresses by means of the force parallelogram. For dimensions of such trusses, see ¶ 266.

149. In the wooden roof truss, Fig. 43, uniformly loaded along each rafter, let H I = the weight of one rafter and its load. Then E I = the horizontal pressure of the head and of the foot of that rafter (the latter being the tension in the chord), and H E = the inclined pressure at its foot.

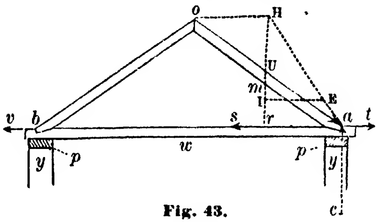

Fig. 43.

150. In Fig 44, make G R = H I. Then G L is the transverse pressure of the load against the rafter as a beam, and L R is a longitudinal pressure along the rafter, forming a *part* of the *total* longitudinal pressure

151. If G R were concentrated at G, L R would be uniform from G to *a*, and would not be exerted above G; but, as G R represents a load uniformly distributed along the rafter, from top to foot, the pressure represented by L R increases uniformly, from nothing, at the top, *o*, to L R, at the foot, *a*.

152. Of the transverse pressure, G L, one half, = *o p*, is sustained at the top, *o*, of the rafter, and the other half, = *a q*, at the foot, *a*. At the top, *o p* is resolved into the horizontal pressure, *o b* = E I, against the head of the other rafter, and a uniform thrust, *o z*, along *o a*.

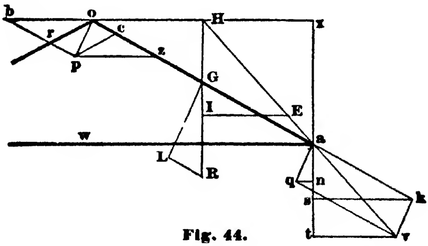

Fig. 44.

153. It is immaterial whether we thus resolve *o p directly* into *o b* and *o z* (as though the head of the rafter rested against a *vertical wall* at *o*), or whether we first resolve it between the two rafters, into *o c* and *o r*. For in the latter case we must add to *o c* a thrust (= *o r* = *c z*) produced in *o a* by the transverse pressure (similar to *o p*) of the head of the *other* rafter; and the sum of these two (*o c* and *o r*) is = *o z*.

154. The total longitudinal thrust in the rafter increases uniformly from *o z*, at the top, to *o z* + L R = *a k*, at the foot, where it combines with *a q* (= half the transverse load) to form *a v* = H E.

155. Tension in chord = I E = *t v* = *s k* — *n q*. Vertical pressure on support = H I = *a t* = *a s* + *a n* = *a s* + *s t*.

156. In Fig. 45, having found, as for Fig 44, the stresses, etc., due to the rafters and their loads, remember that the king rod, $o\ n$, supports its own weight plus the portion $y\ y$ of the chord = ½ the chord. Making $o\ t$ = this combined weight, we have $o\ m = o\ d$ = an additional pressure, uniform throughout each rafter, and $c\ m = c\ d$ = an additional tension on the chord.

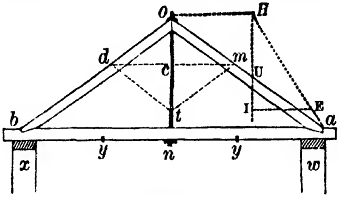

Fig. 45.

157. In Fig. 46, assuming, for safety, that the rafter, $j\ b$, is divided at its center, U, make $e\ o$ = the weight of $z\ r$ and its load ($z\ r$ = half the rafter).

158. Then $e\ i$ = an additional pressure on U b, $e\ k$ = pressure on U c; $s\ i - s\ k$ = additional tension on half chord, $c\ b$, and $e\ o = 2\ e\ s$ = load of and on $z\ r$, = additional tension on king post due to both struts. Then make $a\ g = e\ o$ + weight of king rod + weight of two struts + weight of and on $y\ y$, and proceed as in Fig 45.

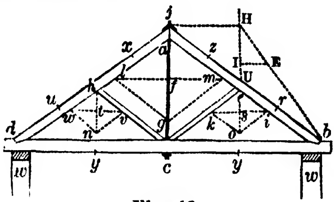

Fig. 46.

159. Each strut will thus bear *half* of the weight of and on $z\ r$, or $x\ u$, only when, as in Fig. 46, the inclination of the strut is the same as that of the rafter. If the strut is steeper than the rafter, it will bear more than half; but if it is less steep than the rafter, it will bear less than half; the remainder being in every case borne by the rafter.

160. The introduction of the struts converts each rafter, considered as a beam, into two beams of shorter span and bearing less loads.

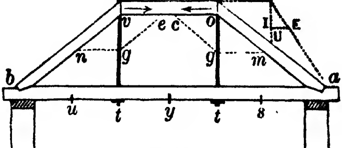

Fig. 47.

161. In the queen truss, Fig. 47, make $o\ g$ = total tension in queen rod + half weight of and on the "straining beam," $z\ w$. Longitudinal pressure on $z\ w$ = tension in chord, $b\ a$, = I E + $o\ c$.

Deflections.

162. The total deflection of a truss * comprises (1) the elastic or temporary deflection, due to the stretch† of its several members under the loading applied to the truss, and (2) the non-elastic or permanent deflection, due to looseness of its joints. In good construction the latter is relatively negligible in moderate spans.

The total elastic deflection, D, of a truss, at any point, *c*, is made up of partial elastic deflections, *d*, *d*, etc., at *c*, each due to the stretch, *k*,† in some member.

Let it be required to find the deflection at a panel point, *c* (usually the center of a span or the end of the arm of a swing bridge or other cantilever); and, for any load or system of loads, let

D = the total elastic deflection at *c*;
d = the partial elastic deflection, at *c*, due to the stretch, *k*,† in any member;
p = the unit stress in that member;
P = the total stress in that member;
l = the length of that member;
k = the stretch † in that member $= \frac{p\,l}{E}$;
W = that load which, applied at *c*, would produce the stress, P, in that member;
$u = \frac{P}{W}$;
E = the modulus of elasticity of the material, $= p \div \frac{k}{l} = \frac{p\,l}{k}$.

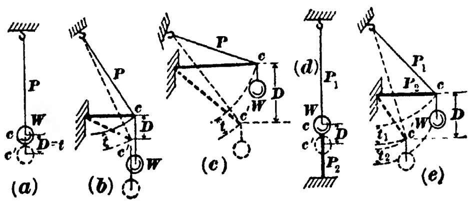

Fig. 48.

163. Equivalence of Work. In Fig. 48, let any load, W, be applied at any point, *c*, of a truss or bar. Then, for a small deflection,‡ such as may

---

* See "The Application of the Principle of Virtual Velocities to the Determination of the Deflection and Stresses of Frames," by Geo. F. Swain, Jour. of the Franklin Institute, vol. LXXXV, 1883; "Trusses with Superfluous Members," by Wm. Cain, Van Nostrand's Magazine, vol. XXVII, No. 4, October, 1882; "The Graphical Solution of the Distortion of a Framed Structure," by David Molitor, Jour. Ass'n Eng'ng Societies, vol. XIII, No. 6, June, 1894; and "The Theory and Practice of Modern Framed Structures," by J. B. Johnson, C. W. Bryan and F. E. Turneaure, New York, John Wiley & Sons.

† For brevity we here use the word "stretch" to signify any change of length, including the shortening due to compression, as well as the elongation due to tension.

‡ For the sake of clearness, the stretches and deflections, in our Figs., are exaggerated beyond the limit within which the ratio, $\frac{P}{W}$, would remain even approximately constant.

be permitted in trusses, the external work, W d,* of a partial deflection, d, due to the stretch, k, in any member, is practically = the internal work, P k, of overcoming the resisting stress, P, in that member, through the distance, k; or

$$W\ d = P\ k.$$

Hence,

$$d = \frac{P}{W}\ k = u\ k; \quad \text{or} \quad \frac{k}{d} = \frac{W}{P}.$$

In words, the stretch, k, in any one member, is, to the resulting partial deflection, d, at c, inversely as is any stress, P, in that member, to a load, W, which, if applied at c, would cause that stress.

Thus, in Fig. 48 (a), where k is in the same direction as D,† P = W, and D = k.

In Figs. (b) and (c),‡ suppose the strut incompressible. Then D is due solely to the elongation of the tie, and $D = \frac{P}{W}\ k = u\ k$.

In Fig. (c), $\frac{P}{W}$ is greater, and (for a given stretch, k, in the tie) D is therefore greater, than in Fig. (b).

164. Deflection Independent of Nature of Cause of Stretch. Now it is evident that the deflection, d, at c, depends solely upon the amount and character of the stretch, k, in the member, and is independent of the nature of the cause of that stretch. That is to say, any change, k (however caused), in the length of the member, necessarily contributes its fixed quota, $d = \frac{P}{W}\ k$, to the total deflection, D, at c. In other words, since d and k are mere distances, and since u is simply a ratio, the relation between d and k is a purely geometrical one, and is therefore not confined to deformations produced by applied loads, but is applicable also to those produced by changes of temperature, to intentional lengthening or shortening of members, or to any other cause

Hence, if a member be *in any way* lengthened or shortened, by a length, k, a corresponding change, $d, = \frac{P}{W} . k = u\ k$, takes place in the deflection at c.

For instance, if we place any system of loads upon a truss, and, by the principles of statics, determine the resulting total stress, P, and unit stress p, in any member; we have, for the partial deflection, at c, due to the stretch, k, in that member, under the given system of loads,

$$d = u\ k; \qquad \text{(For } u\text{, see ¶ 165.)}$$

and, since $k = \frac{p\ l}{E}$,

$$d = \frac{p\ u\ l}{E}.$$

165. To obtain the ratio, $u, = \frac{P}{W}$, for each member, we suppose a concentrated load applied at c; and, by the principles of statics, find the resulting total stresses, P, P, etc., in the several members. If the supposed load, at c, be taken = unity, the stresses, P, P, etc., so found, are the desired ratios, u, u, etc.

---

* Strictly speaking, with a load increasing gradually from 0 to W, and with resulting stress increasing gradually from 0 to P, we should deal with the *mean* load, = ½ W, and with the *mean* stress, = ½ P, in each member; but it will be seen that this would not affect the equations derived.

† Where, as in Figs (a), (b) and (c), only one member is supposed to change its length, D = d.

‡ See note (‡) on preceding page.

166. Summation of Deflections. The total deflection, D, at c, under the given system of loads, being = the sum of the partial deflections, d, d, due (but not necessarily equal) respectively to the stretches, k, k, in the several members, we have

$$D = \Sigma\, d = \Sigma \frac{p\, u\, l}{E}.$$

Thus, in Figs. (d) and (e), we assume the tie extensible and the strut compressible. In Fig. (d), $W = P_1 + P_2$; and $W\,D = P_1\,k + P_2\,k = (P_1 + P_2)\,k$. Hence $D = \Sigma\, u\, k = \frac{P_1}{W} \cdot k + \frac{P_2}{W} \cdot k = \frac{P_1 + P_2}{W} \cdot k = \frac{W}{W} \cdot k = k$. In Fig. ($e$), $D = \Sigma\, u\, k = \frac{P_1}{W} \cdot k_1 + \frac{P_2}{W} \cdot k_2 \quad u_1\, k_1 + u_2\, k_2$.

167. Positive and Negative Stretches. In some cases it may happen that the change of length of a member diminishes, instead of increasing, the total deflection at the point, c, in question, and must therefore be taken as negative in summing up the values of $u\,k = \frac{p\,u\,l}{E}$; but when c is the middle point of a span, or the end of a cantilever, all the changes in length of the members ordinarily contribute to the deflection, and must therefore be taken as positive.

Theoretically, the formula, $D = \Sigma \frac{p\,u\,l}{E}$, applies also to the deflections of arches, dams and other structures composed of blocks; but, owing to the uncertainty of the values of E, and to the relative inaccuracy of finish in masonry work, it is of but little practical utility in such cases.

168. Redundant or Statically Indeterminate Members. Trusses frequently contain members whose stresses cannot be found by the principles of statics. Thus, in Fig. 11 (c), the two diagonal tension members meeting at the top of either end post are said to be redundant, or statically indeterminate, because the principles of statics do not enable us to determine what proportion of the total load goes to the supports through each of the two systems, Figs. 11 (a) and (b), composing Fig. 11 (c). But the deflection formula, just given, enables us to determine the stresses in such members; for, by means of it, we may find, separately, the deflection in each of the two systems, Figs. 11 (a) and (b); and the part load, transmitted to the supports through each of these two systems, is inversely proportional to their deflections.

BRIDGE DETAILS AND CONSTRUCTION.

General Principles.

169. In general, a truss **bridge** consists essentially of two or more vertical **trusses**, AB, CD, Fig. 49, placed side by side, and connected by the **floor system**, which, in turn, they support; and bracing (forming a "**lateral system**") is supplied between opposite chords, where practicable, in order to maintain the trusses parallel.

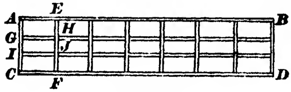

Fig. 49.

170. The **floor system** consists ordinarily of **floor beams** and **stringers.** The floor beams, AC, EF, etc., Fig. 49, are placed transversely to the bridge, and are attached to the trusses at opposite panel points. Connected with these and perpendicular to them or parallel to the trusses, are the stringers, GH, IJ, etc. In railroad bridges, there are usually two or more stringers placed side by side and running the length of the bridge, to support the ties. In city highway bridges, these stringers are usually spaced at smaller intervals, and support buckled plates or other form of flooring, on which the

paving is laid. For country highway bridges, the stringers are frequently of wood, placed quite near together, and the planks of the floor are nailed or spiked directly to them.

Solid floors (see Pencoyd floor sections) add to the rigidity and permanence of a bridge, and give increased protection to traffic below, against injury from falling bodies or in case of derailment. Their shallowness is an advantage where head-room is an object.

171. Any load, then, **is carried** first from the ties or floor, etc., to the stringers, then by the stringers to the floor beams, and finally by the floor beams to the panel points of the bridge, where it is carried through the trusses to the supports.

172. Pedestals, shoes or bed plates, Fig. 62, bolted to the piers, support the ends of the trusses. When the bridge is of long span, so that the expansion and contraction due to heat and cold are considerable, **expansion bearings,** Figs. 60, 62, must be provided at one end. See ¶¶ 205, etc. For cross-bracing, see ¶¶ 19, etc.

General Character of Design.

173. Flexible and Rigid Tension Members. Adjustable Counters. Until recently, **eye-bars** have generally been used for the tension members of trusses. These are long flat bars, liable to yield laterally under compression, and furnished, at their ends, with eyes or openings, through which pass pins connecting them with the other members of the bridge; but rigid built members, capable of sustaining some compression, as well as tension, are now much used for tension members. **Counters** were usually made in two lengths, and were **adjustable,** the two lengths being connected by turnbuckles; but these rendered it possible to bring undue and dangerous stresses in the panels, and they are now giving place to counters made each in one length.

174. Compression members are ordinarily **"built up"** of angles and plates, or of channels and plates with latticing, in hollow shapes, bringing most of the material as far as possible from the neutral axes of the cross-section and thus increasing its resisting moment.

175. Pin and Riveted Connections. The web members are connected with the chords either by pins or by rivets. In the former case the truss is said to be pin-connected; in the latter case, riveted.* Until recently, pin-connected trusses have been typical of American practice; but the Americans are now largely using riveted trusses, for spans up to from 150 to 175 ft., while the Europeans are in some cases using pins. The principal advantage claimed for the riveted joint is that it makes a stiffer bridge and one that will not rattle, and that a riveted truss, computed as if pin-connected, will have an additional margin of safety on account of added stiffness. In the pin-connected bridge, on the other hand, the stresses can be much more accurately determined, and deflection may take place without producing twisting or bending stresses in the connections themselves.

176. Tendency to Greater Rigidity. There is a growing tendency to use stiffer bracing, to design at least all short braces for compression, and to make even the longer tension members of channels or angles, forming a rigid member. Unless pin-connected eye-bars are of exactly equal length, some of them will receive more than their share of the total stress.

177. Floor-beam Connections. In the United States, floor-beam connections were formerly made by hanging the floor beams from the pins by means of hangers; but now, where possible, the ends of the floor beams are riveted directly to the inner sides of the posts.

178. In tension members, rivets are so arranged as to reduce the net effective section as little as possible.

179. Compression members are so designed as to place most of the material as far as possible from their neutral axes, and they are sometimes strengthened by auxiliary ties or posts supporting them at their middle points, in cases where the resulting saving in material for the member will be considerably greater than the expenditure of material in the auxiliary member.

---

* Riveted trusses are unfortunately called, also, "lattice girders," "lattice trusses," "riveted lattice girders" and "riveted lattice trusses." The term "lattice" is often applied to shallow trusses with numerous panels.

180. So far as possible, compression members are made equally strong against bending about either of the two principal axes, AB and XY, Fig. 52, of their cross-sections.

181. Where the same member occurs many times in a bridge, and where, therefore, an excess of material in the design of such member would involve a large total waste, the computation of the member is repeated many times until the most economical section is found.

182. In metal trusses the shorter members are usually made to withstand compression, and the longer ones tension, this being more economical of material. Thus, the Pratt truss, with diagonal tension members, is used for steel bridges, while the Howe truss is now built only with wooden diagonals.

Tension Members.

183. In eye-bars, area of cross-section $= \dfrac{\text{maximum tensile stress}}{\text{allowable unit tension}}$.

184. The dimensions of the heads of eye-bars are usually determined by the manufacturers, and are so designed as to give ample excess of strength at the pin-holes, so that, if tested to destruction, fully two-thirds of the number of bars tested shall break in the body of the bar, this being usually required by specifications. It is important that the proportions of eye-bar heads should be such as to ensure thorough working of the metal in the upsetting process.

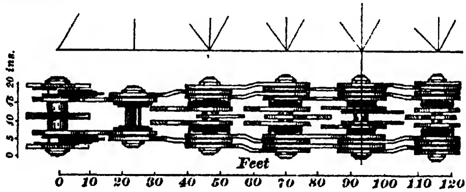

Fig. 50.

185. Fig. 50 shows, to two different scales, the "packing" (arrangement of pins and eye-bars) in the left half of the lower chord of a 150 ft. through (skew) span built by the Phœnix Bridge Co. in 1900 for the Philadelphia and Reading Railway Co. near Reynolds, Pa.

186. Built Sections. Hip vertical hangers, non-adjustable counters and their corresponding mains, are usually built up of rolled steel shapes. A section in common use shown in Fig. 51, consists of four angles, connected, at intervals, by small narrow flat bars, riveted to the angles and running across zigzag from one to the other. When single, as in Fig 51, this is called "lacing"; when double, as in Fig. 52 (*b*), "latticing." The shaded area of the angles, Fig. 51, minus that of the rivet holes, is taken as the effective section.

187. Minimum Sections. Specifications (see Digests) usually require the use of some minimum section. Thus, in a counter in which the stress is 58,000 lbs., 3.5 square inches of cross-section would suffice; but specifications frequently forbid the use, in such sections, of any angle smaller than $3\frac{1}{2} \times 3\frac{1}{2} \times \frac{3}{8}$, which gives 9.20 square inches gross; or, deducting one rivet hole from each angle, 7.68 square inches net section.

Compression Members.

188. The computation of a compression member consists of a series of approximations; for the unit stress depends upon the radius of gyration, the radius of gyration on the area of section and disposal of material with regard to the axes, and this, in turn, on the unit stress. See Columns, under Strength of Materials.

189. Fig. 52 (*a*) shows a form often used for posts, and consisting of **two channels,** placed with their backs outward and riveted together by lacing. In Fig. 52 (*b*) the channels are placed with their backs inward. For economy, the channels should be so spaced as to make the radius of gyration the

same about either axis, A–B or X–Y. The radius of gyration is given in the hand-books of mfrs of structural shapes. See pp. 1174, etc.

190. The upper chord section is frequently **built up** of two channels and a plate, or in some such form as shown in Fig 53, consisting of two vertical plates or "webs," a horizontal top plate or "cover," four "angles," and flat pieces or bars on each side of the bottom Lattice bracing, or lacing, is provided along the bottom, except at panel points, where it is omitted in order that the post and the ties may enter the chord from below. In pin-connected trusses the axis of the pin lies in the line AB.

191. The interior width, *w*, depends chiefly on the space required by the post and ties which meet at the panel point, and also upon the height of the inside rivet heads. Usually, for convenience of construction, the greatest width, *w*, required is kept constant throughout the upper chord. The height, H, depends chiefly on the size of eye-bar head, and is kept constant. The thicknesses of the web plates, and sometimes also those of the bars and angles, are varied, along the chord, in order to provide, at each point, sufficient area to withstand the stress.

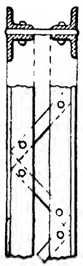

Fig. 51.

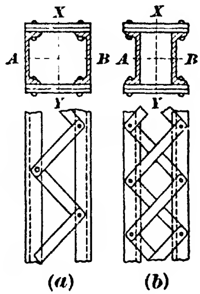

Fig. 52.

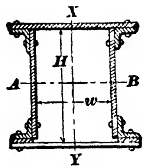

Fig. 53.

192. The **end post** is to be considered not only as a column, but also as a beam subject to shear, on account of the wind blowing against the top of the side of the truss. The design of this built-up form is much the same in principle as that given above for a post. Certain sections are tried, and then changed if necessary.

193. The end post must be safe, not only against bending about the axis, A–B, Fig 53, under compression, but also against bending about the other axis, X–Y, under the combined effect of compression and the bending moment, due to the wind blowing against the top of the truss. See Fig. 54 (*a*).

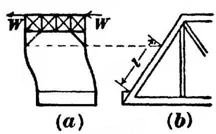

Fig. 54.

194. The portal bracing, above, and the floor beam, below, are assumed to prevent bending of the parts of the posts adjacent to them; and we may consider either half of either post ($= \frac{1}{2}\, l$) as a vertical cantilever, fixed at one end, and loaded, at the other end (which is at the middle of the post) with a load = wind pressure on half the upper portion of one truss.

195. The maximum stresses, due to compression, of course occur about the middle of the post, while those due to the wind occur near the ends. Hence it would be unreasonable to require the post to resist all of both effects simultaneously throughout its length; and specifications therefore usually allow the unit stress, due to dead, live, impact and wind loading combined, to be increased to 21,000 lbs. per sq. in., properly reduced by formula for compression.

196. Long compression members are designed with a view to their liability to failure by buckling sideways. The formulas in common use are the Rankine (often miscalled the Gordon): $p = s/(1 + m\,K^2)$, and the "straight-line": $p = s - c\,K$. Here

p = mean unit load on column = total load ÷ solid cross-section area;
s = max unit stress in cross-section;
$K = L/r$ = unsupported length ÷ least gyration radius;
m and c = coefficients.

See also pp 495, etc, 760-761, 764, 1194-1195, 1143-1148.

197. The formula for extreme fiber stress due to combined compression and bending, is

$$S = \frac{P}{A} + \frac{M_b\,T}{I - \dfrac{P\,l^2}{E\,c}}.$$

Where
P = longitudinal compressive force;
A = area of section;
M_b = bending moment due to transverse load;
T = distance from neutral axis to extreme fibers;
I = moment of inertia;
l = length of beam;
E = modulus of elasticity;
c = coefficient. See Transverse Strength, ¶ 103.

Joints.

198. Pin Plates. Where a pin passes through one or more shapes of some member, if often happens that the combined surfaces of the truss members alone, in contact with the pin, are insufficient to transmit, by bearing, all of the stresses to be delivered to the member. There is then danger of crushing the material which presses against the pin. To obviate this, other shapes, usually flats and called pin plates or reinforcing plates, are riveted to the member; giving, in all, sufficient bearing surface for the pin. See Fig. 55; where the letters denote:

AA, angles,	W, web,	F, filler,
C, cover,	P, pin,	O, outside pin plate,
B, bar,	J, jaw,	T, batten plates.

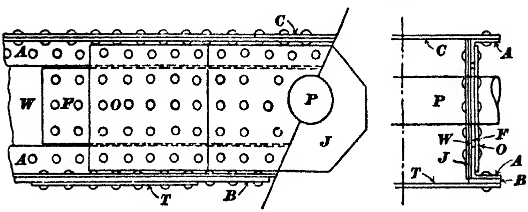

Fig. 55.

199. In Fig. 56, the two channels form the *whole* member (except the latticing, which cannot be included to resist compression) and the pin passes through both channels. In the case of a built-up chord section, or of an end post; Fig. 53, however, the webs form only a part of the section;

while the cover, the angles and the flats can receive no stress directly from the pin, but must receive it indirectly from the web and from the pin plates attached to it.

200. Where a pin plate is placed on each side of the web, the outside one must, according to most specifications, cover the angles; and there must, in addition, be a "**filler**" between it and the web.

201. Engineers differ as to the manner in which the stresses are actually transferred through the several parts of a pin connection. We may assume that the stresses in the pin plates are delivered almost directly to the shapes of the member. Thus, the outer reinforcing plate probably delivers most or all of its stress to the angles, and little or none to the web.

202. In each angle, those rivets which pass through the inner pin plate must transmit, by means of their bearing against the angle, the sum of the stresses which they take by shear from inside and from outside. In other words, these rivets are in double shear.

Pins.

203. The pin must be designed to resist bending stresses from the members through which it passes. It is also subject to shear, but this is seldom a critical point.

204. The pin requiring the greatest cross-section is usually either the one at the middle of the span and in the lower chord, where the chord stresses are greatest, or the one at the joint between the end post and the top chord; but, as the pins are relatively small members, all the other pins are, for the sake of uniformity, usually made of the same size with it.

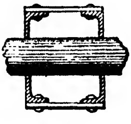

Fig. 56.

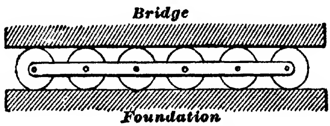

Fig. 57.

Expansion Bearings.

205. Expansion bearings usually consist of a nest of carefully turned rollers placed between two planed surfaces, shown in principle in Fig. 57.

206. The rollers are steel cylinders, from 3 to 6 ins. diam.; and 1 to 4 ft. long; planed smooth. From 4 to 8 or more of these are connected together by a frame, and one such frame is placed under at least *one end* of the truss. The rollers rest upon a strong planed cast bed-plate; bolted to the masonry below. Under the end of the truss is a similar plate by which it rests on the rollers. Since a truss of even 200 ft. span will scarcely change its length as much as 3 ins. by extremes of temperature, the play of the rollers is but small. They are kept in line by flanges cast along the side of the bed-plate. Flanges should also project downward from the upper bed-plate, so as completely to protect the rollers from dust, rain, etc.

207. The total displacement, allowed for the free end of the truss, is usually specified (see Digests); otherwise it may be taken as

$$D = \frac{(T - t)\ \text{span}}{145{,}000},$$

where T and t = the max. and min. temps. respectively, in degrees F. The min. temp. to be expected may be obtained from Weather Bureau records of temps. in the shade, but the max. should be taken 20° or 30° higher than that of the Weather Bureau; because, in bright sunshine, the bridge will become much hotter than the air.

208. Rockers. In order to restrict the length of the bearing, where the displacement is moderate, rockers, Fig. 62, are often used instead of rollers.

209. For other regulations and suggestions regarding design of roller bearings, see Digests of Specifications, and Figs. 60 and 61.

Loads, Etc.

210. Loads, Clearance, etc., for Highway Bridges. See also Digests of Specifications for Bridges.

Weights of crowds. At the Chelsea bridge, London, picked men, packed upon the platform of a weigh-bridge, gave a load of only 84 lbs. per sq. ft. At Buckingham Palace, men, wedged as closely as possible upon a space 20 ft. in diameter, the last man lowered from above, among the others, gave 120 lbs. per sq. ft. But modern experimenters have easily obtained loads of from 140 to 150 lbs. per sq. ft. With picked men, averaging 163.2 lbs. each, all facing one way, carefully packed, and confined within an enclosure 6 ft. square (0.9 sq. ft. per man), Prof. L. J. Johnson, at Harvard University, obtained a maximum of 181.3 lbs. per sq. ft.* See also pages 755, etc.

Where the enclosure of the space is such that portions of the persons, standing against the enclosure, may project beyond it, the load, per unit of space, is of course increased; and, with small areas, this increase may be relatively important.

Camber.

211. Amount of Camber. If we divide the span in feet, by 50, the quot. will ordinarily be a sufficient camber, in inches. This amounts to 1 in 600. The camber to be used is, however, usually stipulated in the specifications. See Digests. A well-built bridge, of good design, should not, under its greatest load, deflect more than about one inch for each 100 feet of its span, or 1 in 1200. Indeed, the deflection is frequently much less than this

212. The excess of length of the upper chord over that of the lower one, given the span, the depth of truss and the camber, will be =

$$\frac{8 \times \text{depth} \times \text{camber}}{3\ \text{span}}.$$

This rule applies closely with any camber not exceeding 0.02 of the span.

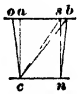

Fig. 58.

213. Length of diagonal cb, Fig. 58, $cb = \sqrt{ac^2 + ab^2}$; where ac = depth of truss, and $ab = cn + \frac{ob - cn}{2}$.

214. Sometimes the elongation or shortening, produced by the loading, is computed for each member, and the length of each member affected is correspondingly changed. See Deflections, ¶¶ 162, etc.

Examples.

215. Figs. 59 (*a*) to (*u*), to a uniform scale of 1 inch = 60 feet, serve to indicate current practice respecting the types selected for different spans, the relation between span, panel length and depth, the spacing of stiffeners in plate girders, the arrangement of chord and web members, the use of rigid and flexible members, counters and turnbuckles, in trusses, and, approximately, the dimensions of rigid members and of gusset plates, as seen in elevation.

216. In each case the left half of the span is shown, and the center line of the span is indicated by a dot-and-dash line. Through spans and deck spans are distinguished by the elevation of the roadway, as approximately indicated at the left support.

217. In Figs. *h* to *q*, representing trusses, rigid members are indicated by double lines, flexible members in verticals and main diagonals by single lines, and counters by dotted lines. In pin spans, to avoid confusion, the rigid members are shown cut off near the pins.

218. Figs. (*a*) to (*o*) represent standard designs, from 25 to 200 ft. span, by Mr. Ralph Modjeski, C.E., for the Northern Pacific Railway Co.; Fig. (*p*) a 250 ft. railroad span designed by the Pencoyd Works of the American Bridge Co.; Fig. (*q*) a 308 ft. railroad span by the Phœnix Bridge Co.; Figs. (*r*) to (*t*) designs for riveted trusses by the Elmira Works of the American Bridge Co.; and Fig. (*u*) a riveted railroad bridge, of 102 ft. span, designed by the Pencoyd Works

* Journal, Ass'n Engng Socs, Jan., 1905.

219. Fig. (*a*) represents a beam girder; Figs. (*b*) to (*g*) plate girders; and Figs. (*h*) to (*q*) riveted and pin trusses; Figs. (*h*) and (*i*) being riveted, and Figs. (*j*) to (*q*) pin.

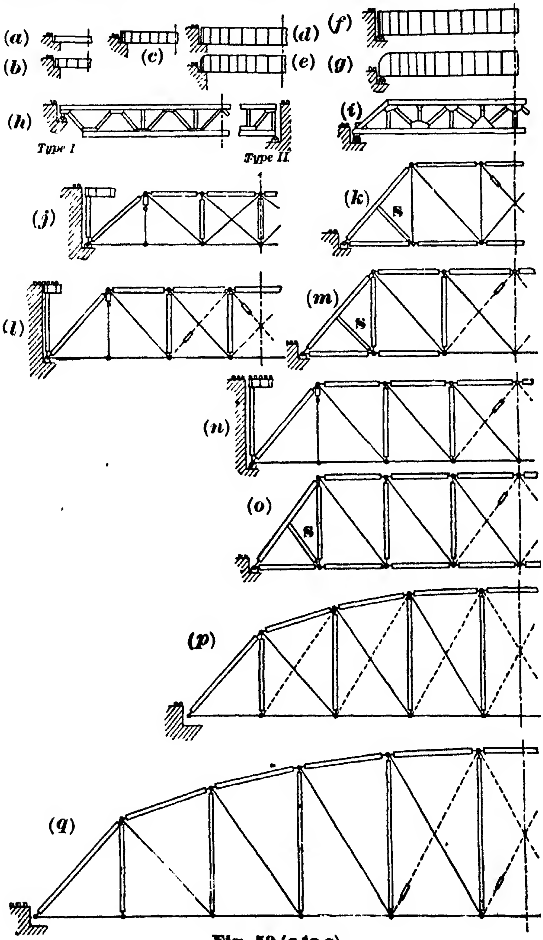

Fig. 59 (a to q).

220. Fig. (*r*) represents a 128 ft. span for the New York Central and Hudson River R. R., and Figs. (*s*) and (*t*) spans of 143 ft. and 160 ft. respectively for the Delaware, Lackawanna and Western R. R. Figs. (*r*) and (*s*) are modifications of the Baltimore truss, Fig. 15 (*b*), and Fig (*t*) is a quadruplex Warren truss. Fig. (*s*) is a skew span. Fig. (*u*) is a "pony" span.

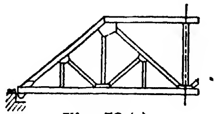

Fig. 59 (*r*).

225. Weights of Steel Railroad Bridges. Fig. 66, based upon the practice of the Northern Pacific Railway, 1902,* shows the approximate

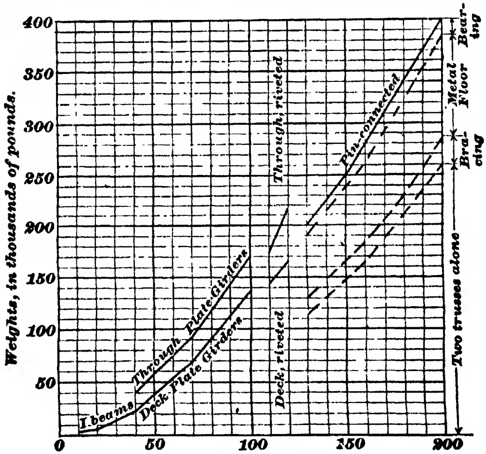

Fig. 66.

* See paper by Ralph Modjeski, C.E., in "Journal of the Western Society of Engineers," Chicago, Feb., 1901, vol. vi, No. 1.

weights of steel railroad bridges designed for two locomotives, of 146 tons each, and a uniform train load of 4000 lbs. per foot of track. The weights include the two beams, girders or trusses of one single-track span, with their bracing, metal floor system and end bearings. For wooden floor system, add 400 lbs. per lineal foot. For pin-connected spans (130 to 200 ft.), the three dash diagrams show, respectively, the weights of two trusses alone, of two trusses and bracing, and of two trusses, bracing and metal floor. The solid curve includes weights of end bearings.

For weights of combination (wood and iron) railroad bridges, see ¶ 249.

Highway bridges differ so widely, as to service and design, that it is scarcely practicable to give here useful data as to their weights.

List of Large Bridges.

Each bridge here given is believed to be (1902) the largest of its type in the world.

Type	Spanning	At	Span, ft	Built
Truss, ...	Ohio River	Louisville	553	1893
Swing, ...	Missouri River	Omaha	520	1894
Suspension, ...	East River ("Brooklyn")	New York	1595	1883
Suspension, ...	East River ("New")	New York	1600	*
Arch (metal), ...	Niagara River	Niagara Falls	840	1898
Arch (stone), ...	Petruff Valley	Luxembourg	277	*
Cantilever, ...	Firth of Forth	Queensferry	1700	1890

The highest viaduct is the Gokteik Viaduct, in Burmah, with a maximum height of 320 ft., and a total length (composed of short spans) of 2260 ft. built in 1901.

Timber Trusses.

226. Timber is now becoming so expensive, except in unsettled regions, and the labor of designing so cheap, that it is no longer found to be good practice to use unnecessarily heavy timbers, simply for the sake of being "on the safe side" and avoiding computations. Hence, in important bridges, every part of each member under stress is usually computed. On the other hand, the strength of wood is so uncertain an element that, when in doubt, it is best to adopt that assumption which will require the larger section; and ample factors of safety should be used.

227. Compression members are designed as columns (see Columns, pp 495, etc., and Wooden Columns, pp 963, etc.); and, if subjected to transverse stresses as well, these also should be carefully taken into account. All holes and other reductions of section must of course be deducted from the gross section.

228. In the **tension members** also, all reductions of section must be considered; but iron or steel rods are now generally used, in place of wood, in tension members.

229. In addition, care should be taken that the timber can withstand any **crushing or shearing** stresses that may come upon it or be set up in it. Thus, the ends of posts should be investigated, to see that they are safe against crushing. Where a post meets another member at an inclined angle and is to be notched into it, it is economy to compute the depth of notch required; as, the deeper the notch, the greater the gross section required for the notched member. Where bolts are fastened to timbers by nuts, washers should invariably be placed under the nuts, and the size of washer, necessary to prevent crushing the wood, computed.

230. Where the wood is subjected to shearing, as where a bolt, passed through a timber, transmits stress by the bearing of its side against the inside of the hole, or where there is a step or table which may be sheared off by the pressure of another piece against it, it should always be seen that there is sufficient surface along the grain of the wood to take the shear, and some allowance should be made for the possibility that the grain may run out to the surface or to some hole before all the stress can be transferred.

* Under construction. 1902.

231. Cross-section of Upper Chord. Since it would be inconvenient, in practical construction, to change the section of a timber upper chord at different points, it is designed throughout to withstand the *maximum* stress occurring between any two panel points. Assume width of chord member. Find r^2 = (least radius of gyration)$^2 = \frac{(\text{width})^2}{12}$. Find allowable unit stress according to column formula given in specifications or adopted, using the given maximum stress. Find area required for this unit stress. Find the resulting depth, which for a horizontal or inclined member is preferably somewhat greater than the width, to allow for bending moment due to its own weight. If this does not give a good commercial size, it may be well to revise, in order to obtain a better section.

232. Struts are preferably made as wide as the upper chord. Each strut must be designed separately. Obtain r^2, allowable unit stress, etc., as for the upper chord. For economy, the struts should average nearly square, even though it should be necessary to alter the section of the upper chord in order to prevent wide deviation from a square section.

233. The **vertical ties** (of iron) may now be designed. Area of cross-section $= \frac{\text{maximum stress}}{\text{allowable unit stress}}$. But see Minimum Section, ¶ 187. The size of a nut is usually fixed by the diameter of the rod, but the washers should be so designed as not to crush the wood.

234. The **bearings** or **indentations**, required in the upper and lower chords to hold the inclined members in place, may now be computed. The component (in the strut) perpendicular to the face or faces against which it presses, is computed, and the necessary depth obtained, assuming the width of the lower chord the same as that of the upper chord and the struts.

235. The section of the **lower chord** may now be decided upon, since the reduction of section, due to indentations, is known.

$$\text{Area of net cross-section} = \frac{\text{maximum stress}}{\text{allowable unit stress}}.$$

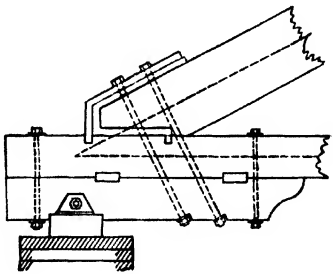

Fig. 67.

236. End Joint. Fig. 67. Many different designs for end joints have been made, proposed and discussed. The ends of the straps should enter notches in the lower chord, to such a depth that the total stress, taken by the end fibers of the sides of the notches, is equal to the stress that the ends of the straps can resist by bending. This depth can be found by successive trials, or by means of two algebraic equations, in which the maximum allowable pressure and the depth of notch are the two unknown quantities.

Determine the shearing surface required to transmit this stress to the body of the lower chord. This will also determine the space between the notches and the end of the lower chord. Compute the stress (if any) that remains to

be transferred, and design the long inclined bolts and their washers accordingly. Compute also the compressive area and depth of vertical face of lower end of upper chord, required to transmit the horizontal component of its thrust. See also that the lower bearing presents sufficient surface to resist the vertical component. The keys, between the bolster and the lower chord, must be designed to carry the horizontal component of the wind. For safety, **friction** between the two parts should be neglected.

237. Figs. 68 show **joints** adapted to most of the cases that occur in practice with wooden beams, etc. They need but little explanation. Fig. (*a*) is a good mode of splicing a post; in doing which the line *o o* should never be inclined or sloped, but be made parallel to the axis of the post; otherwise, in case of shrinkage, or of great pressure, the parts on each side of it tend to slide along each other, and thus bring a great strain upon the bolts. When greater strength is required, iron hoops may be used, as at *b*, *h* and *j*, instead of bolts. Fig. (*b*) shows a post spliced by 4 fishing pieces; which may be fastened either by bolts, as in the upper part; or by hoops, as in the lower. The hoops may be tightened by flanges and screws as at *s*; or thin iron wedges may be driven between them and the timbers, if necessary. Fig. C shows a good, strong arrangement for uniting a straining-beam *k*, or rafter *l*, and a queen-post *u*; by letting *k* and *l* abut against each other, and confining them between a double queen-post *t t*; *n n* are two blocks through which the bolts pass. A similar arrangement is equally good for uniting the tie-beam *w*, with the foot *v*, of the queens; with the addition of a strap, as in the figure. Fig. (*e*) is a method of framing one beam into another, at right angles to it. **An iron stirrup,** as at *f*, may be used for the same purpose; and is stronger. Figs. *g h*, *i j* are **built beams.** When a beam or girder of great depth is required, if we obtain it by merely laying one beam flat upon another, we secure only as much strength as the two beams would have if separate. But if we prevent them from *sliding* on one another, by inserting transverse blocks or keys, as at *g*; or by indenting them into one another, as at *i j*; and then bolt or strap them firmly together to create friction; we obtain nearly the strength of a solid beam of the total depth; which strength is as the *square* of the depth. See Horizontal Shear, ¶ 51, under Transverse Strength.

238. The strength of a built beam is increased by increasing its depth at its center, where it is most strained; as in the upper chords of a bridge. This may be done by adding the triangular strip *y y* between the two beams.

239. A piece of plate-iron may be placed at the joints of timbers when there is a great pressure; which is thus more equally distributed over the entire area of the joint; or cast iron may be used.

240. Frequently a simple strap will not suffice, when it is necessary to draw the two timbers very tightly together. In such cases, one end of each strap may, as at *x*, terminate as a screw; and after passing through a cross-bar Z, all may be tightened up by a nut at *x*. Or the principle of the *double key*, shown at K, may be applied. Sometimes, as at A, the hole for the bolt is first bored; then a hole is cut in one side of the timber, and reaching to the bolt-hole, large enough to allow the screw nut to be inserted. This being done, the hole is refilled by a wooden plug, which holds the nut in place Then the screw-bolt is inserted, passing through the nut. By turning the screw the timbers may then be tightened together.

241. When the ends of beams, joists, etc., are inserted into walls in the usual square manner, there is danger that, in case of being burnt in two, they may, in falling, overturn the wall. This may be avoided by cutting the ends into the shape shown at *m*.

242. When a strap *o*, Fig. R, has to bear a strain so great as to endanger its crushing the timber *p*, on which it rests, a casting like *v* may be used under it. The strap will pass around the back *r* of the casting. The small projections in the bottom, being notched into the timber, will prevent the casting from sliding under the oblique strain of the strap. The same may be used for oblique bolts, and below a timber as well as above it. When below, it may become necessary to bolt or spike the casting to the under side of the timber. When the pull on a strap is at right angles to the timber, if there is much strain, a piece of plate-iron, instead of a casting, may be inserted between the strap and the timber, to prevent the latter from being crushed or crippled; see I and I

Fig. 68.

243. Lower Chord Splice. Owing to the length of the lower chord, it may be necessary to splice it, as in Fig. 69, where the splice is a tabled fish-plate joint. The number of tables to be used is largely a matter of trial. The use of too many tables involves too much carpentry, and consequent uncertainty as to distribution of pressures, while the use of too few requires deep notches, which may too greatly reduce the section. These tables must be designed to resist bearing against their ends, and to resist being sheared off. Bolts should be passed through, especially at the ends of the fish-plates, to prevent them from bending outward; and the washers should be so designed as to transmit safely to the wood all the stress that can come on the bolt.

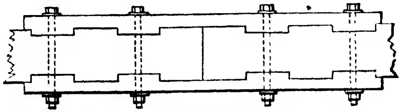

Fig. 69.

244. Fig. 70 shows a lower chord splice used in connection with the standard combination (timber and iron) Howe truss bridges of the Chicago, Milwaukee & St. Paul Railway See ¶¶ 249-251, Figs. 73 Four of the clamp-blocks shown are required for each joint, a block being placed upon each side of each stick to be spliced The two opposite blocks forming a pair are held together, and against the stick, by four through bolts; and the cylindrical lugs, cast on the surface of each block, enter corresponding holes, bored in the face of the stick. The two blocks on the same side of a stick are held together by the hooked clamp-bar. The clamp-key is driven between the left hook and the beveled key-seat on the left block.

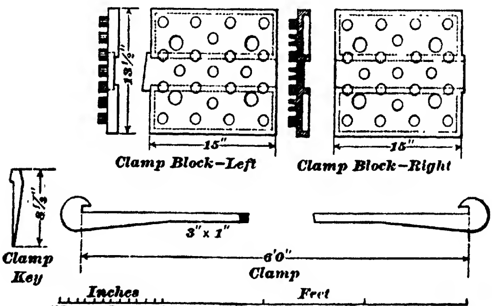

Fig. 70.

245. Figs. 71 illustrate a small wooden **Howe truss bridge.** The top and bottom chords are each made up of three or more parallel timbers *c c c*, placed a small distance apart, to let the vertical tie-rods *r r* pass between them. The main braces, *o o*, are in pairs or in threes. The pieces composing them abut, at top and at bottom, against triangular **angle blocks**, *s*; which, if of hard wood, are solid; and, if of cast iron, hollow, Fig. (*d*), and strengthened by inner ribs. These blocks extend across the three or more chord pieces. Against their centers abut also the counterbraces *c*. These are single pieces in small bridges; or in pairs, in large ones; and pass between the pieces which compose a main brace. Where the wooden braces and

counters cross, they are bolted together. In Fig. (*d*), the dotted lines show the strengthening ribs; and the lug, *x*, keeps the block in place. The vertical tie-rods *r r*, of iron, are in pairs, threes, or fours, etc., according to size of bridge; with a screw and nut at each end. The heads and feet of the braces and counters abut square against the angle blocks; and are often kept in place only by tightening the screws of the vertical ties. The end posts, *p* and *d*, the end ties, *i c* and *b y*, and the horizontal extensions, *g i* and *w b*, of the upper chord, form no part of the truss proper.

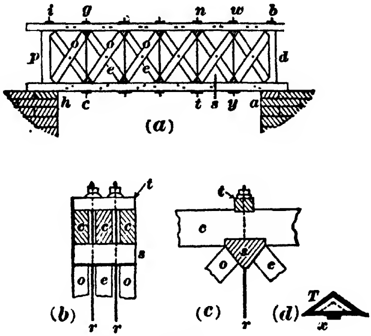

Fig. 71.

246. In **large spans**, to prevent the pressure at the ends of the diagonals from crushing the chords, the angle blocks are sometimes cast with deep projecting flanges under their bases. These flanges, passing between the pieces which compose a chord, extend to the opposite face of the chord. There the flanges bear upon broad washers at the ends of the vertical rods.

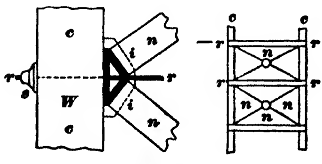

Fig. 72.

247. A common form of **lateral bracing**, Fig. 72, resembles a Howe truss laid flat on its side. In it the diagonals of the cross are struts of timber; and the pieces *r r* are round rods. One of the struts is whole, with the exception of a slight mortise on each vertical side, at its center, for receiving tenons cut on the inner ends of the two pieces which compose the other diagonal. At the sides of the chords, the ends of the diagonals rest upon a ledge (shown by the dotted line *i i*), about 1½ inches wide, cast at the bottom of the cast-iron angle block. The tie-rod *r r*, passing through the chords of both trusses, being tightened by means of the nut *s*, holds the diagonals firmly in place; and, in case of their shrinking a little in time, they can be again tightened up by the same means.

The cast angle block is as deep as a brace; its thickness need not exceed half an inch, in a large bridge. It has holes for the passage of the rod *r r*

248. Dimensions for each of two trusses of a single track **Howe bridge** for highway or suburban electric railway, with cars weighing 20 to 25 tons each. Timber not to be strained more than 800 lbs. per sq. inch; nor iron more than 5 tons per sq. inch. Iron supposed to be of rather superior quality, requiring from 25 to 27 tons (60,480 lbs.) per sq. inch to break it. The rods to be *upset* at their screw-ends. To each of the two sides of each lower chord is supposed to be added, and firmly connected, a piece at least half as thick as one of the chord pieces, and as long as three panels, at the center of the span.

249. Standard "combination" (wood and iron) **Howe truss railroad bridges,** Chicago, Milwaukee & St. Paul Railway, 1891-1902.

The bridges are designed for a train load of 4000 lbs. per lineal foot. Wind stresses are computed for a pressure of 500 lbs per lineal foot of train. Compressive stresses in braces, max. 505, min. 92 lbs per sq inch. Tensile stresses; in main truss rods, max. 12,450, min. 8500 lbs per sq. inch of net area at root of thread. Lateral rods, max. 15,000 lbs. per sq. inch of net section.

Timber. Cross-ties and guard rails, white oak; top chord packing blocks, white pine; all other timber, white or Norway pine or Douglas fir.

Combination Bridges, Chicago, Milwaukee & St. Paul Railway:

* Lengths and spans are given to the nearest foot. The panel length is 10 ft. 11¼ ins. Each span is longer, by one panel, than the next preceding. Depth, in all cases, 25 feet in clear of chords. Width, 14 ft. 6 ins. in clear between chords.

† For lower chord splice, see Fig. 70, ¶ 244.

‡ Owing to the fact that the spans have alternately odd and even numbers of panels, there is some ambiguity as to the dimensions of web members at center of span.

§ Weight includes the two trusses, bracing and floor system for one single-

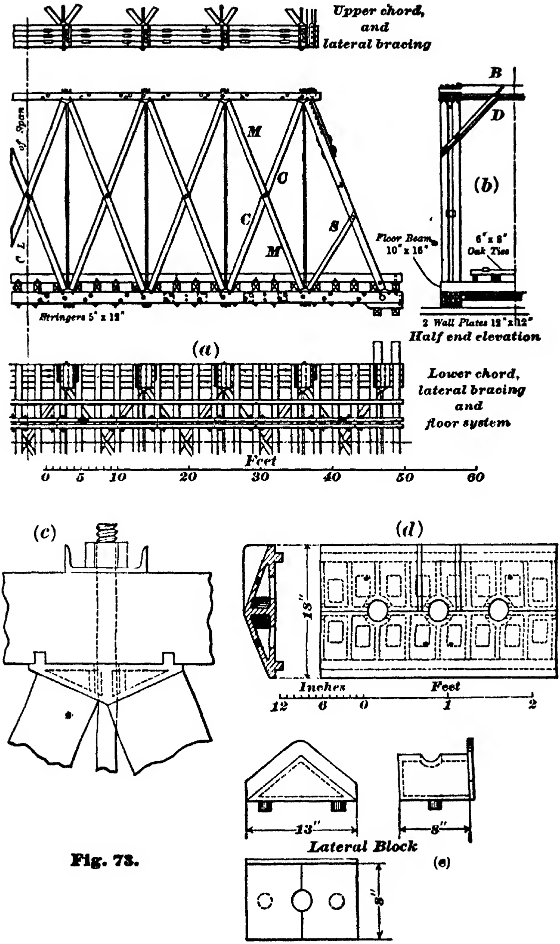

Fig. 73.

track span. Of the total weight of the bridge, the trusses have about 53 per cent., lateral systems 26, floor system 18, and wall plates 3 per cent.

250. In all spans, lateral bracing, 6 × 6 ins. at center, 8 × 8 ins. at ends, of span; lateral rods, 1¼ ins. at center, 1½ to 1¾ ins. at ends; collision struts, S (one at each end of each truss), 6 × 14 ins.; transverse portal brace, B, between ends of upper chords (one at each end of bridge), 10 × 12 ins.; diagonal portal braces, D (two at each end of bridge), 6×8 ins.

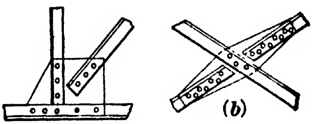
The floor beams are 10 × 16 ins., 20 ft. long, 14 ft. clear span, and 2 ft. 6 ins. apart center to center. The stringers are 5 ins. wide, 12 ins. deep, placed as shown in the end view, Fig. (*b*). Ties, 8 ins. wide, 6 ins. deep, 1 ft. apart, center to center. Guard rail, 8 ins. wide, 5 ins. deep. Under each end of the lower chord are two timber wall plates, 12×12 ins., 20 ft. long.

251. Figs. 73 show the 99 ft. span. Fig. (*a*) is a side elevation of half the span with top and bottom lateral bracing and floor system; Fig (*b*) a half end elevation, showing portal bracing; Fig. (*c*) a panel point connection (the same for upper and for lower chord); Fig. (*d*) a cast-iron angle block for same; and Fig. (*e*) a cast-iron angle block for lateral bracing.

Metal Roof Trusses.

252. Among the types commonly used for metal roof trusses are the triangular truss, Fig. 26, and the arch truss; the triangular truss being used for short spans, and the arch truss for long spans. See ¶¶ 255, etc., and Fig. 75.

253. In roof trusses of short span, carrying light loads, the minimum sections prescribed in bridge specifications will often suffice for all the members. The connections are made by means of rivets and flat plates, somewhat as shown in Fig. 74.



(*a*) (*b*)

Fig. 74.

254. In designing such trusses, no matter how light the stresses, care should be taken to avoid eccentric loadings, which are apt to occur where the members are not repeated symmetrically on both sides of the flat plates.

255. Train-shed Roof, Broad Street Station, Pennsylvania Railroad, Philadelphia. Figs. 75 (*a*) to (*f*). Built 1893 by Pencoyd Bridge and Construction Co., erected by Railroad Co. Span, 300′ 8″; rise, 108′ 6″; length, 589′ 2½″. Twenty trusses, arranged in 10 pairs, 2 pairs shown in Fig. (*c*).

256. Each truss consists of two arched **rafters**, A B and B C, and a horizontal chord, A C, with three pin joints, A, B and C, Fig (*a*).

Each rafter is composed of two chords, 14 radial braces and 26 diagonals. For the sake of appearance, the chords are extended across the top panels, occupied by the two triangular apex members, and are there connected by a sliding joint.

257. The horizontal chord AC, Fig. (*a*), lies below the floor of the train-shed, and is suspended, at intervals, from girders which support that floor and which are carried by iron columns in the lower story.

258. End bearings. One foot of each truss rests upon a fixed shoe, bolted down to the pier; the other on a nest of 11 steel rollers.

259. At each end of the roof, a horizontal wind truss, WW, Fig. (*a*), is suspended from the rafters, its ends resting upon brackets riveted to their lower chords.

260. Between these horizontal wind trusses and the rafters, and just behind the glass curtain closing each end of the roof, are placed vertical wind trusses (not shown), with horizontal and diagonal bracing, in planes normal to the main trusses. These vertical trusses are hung from the lower panel points of the rafters, Fig. (a). They resist the wind pressure on the curtain, and transmit it, through the horizontal wind trusses, to the lower chords of the rafters.

261. Two rafters, AB and BC, Fig. (a), of one truss, together weigh 138,000 lbs.; chord (two lines of eye-bars) 16,000, total 154,000 lbs. One pair of trusses, 308,000. Framework of entire train-shed, including trusses, purlins, rafters and wind bracing, about 7,000,000 lbs.

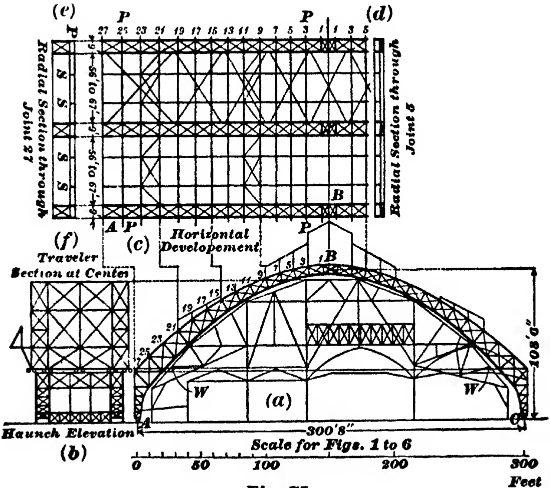


Fig. 75.

262. Assumed extraneous loads, in lbs. per sq. ft. of ground plan: rafters 9 5; laterals and purlins, 7.5; ventilator and skylight framing, 9.5; covering and skylights, 15; snow, 17; wind, 35.

263. The traveler, Figs. (a) and (f), was of timber, and was so designed as to permit the use of the old train-sheds while the new roof was being erected.

264. The top section, from apex to joint 9, Figs. (a) and (c), was riveted up at mill and placed in position as a whole, as was also the foot section from joint 27 to the top of the triangular foot. The remainder was riveted on the traveler. To erect one pair of trusses, with the purlins, etc., connecting it with the pair last erected, required about 10 days. Shifting the traveler through a distance about equal to its own length, to receive the next pair of trusses, required about 3 minutes, and was done by means of the engines used for hoisting.

265. Dimensions of Arched Roofs of Large Span.

	Arches.		Roof.

Timber Roof Trusses.

266. Dimensions for small timber roof trusses, Figs. 43 to 47, ¶¶ 148, etc., of white pine. Span = 4 × rise. Combined weight of trusses, roof and load, including snow and an allowance for wind, 40 lbs. per square foot of roof surface. Trusses 12 feet apart, center to center. Safety factor = 3; b = breadth; d = depth. For Fig. 46, struts 4.5 × 4.5 ins. would suffice; but, for practical reasons, the struts are generally made as wide as the rafters. For Fig. 47, the straining beam is 12 × 12 ins. For Figs. 45, 46 and 47, two sets of dimensions are given; the first for chord unloaded; the second for chord loaded with 100 lbs. per square foot.

Fig.	Span Ft.	Rise. Ft.	Rafters. Ins.		Chord. Timber. Ins.		Chord. Iron. Ins. Diam.	King or Queen Rod. Ins. Diam.	Chord.
			b.	d.	b.	d.

46	40	10	6	8	6	8	1.5	1	unloaded
			8	10	8	15	..	2	loaded
47	60	15	10	12	10	12	1.5	½	unloaded
			12	14	12	12	..	2	loaded

TRANSPORTATION AND ERECTION.

267. Girders should be loaded for **transportation** on flat cars, with web vertical, and with bearings at the points distant ¼ span from the ends. Where too long for two cars, one or more idle spacing cars are used and the points of support are pivoted.

268. Girders may be **erected** by means of gin poles, derricks, gallows, etc., or they may be skidded from the cars and lowered to place by jacks and blocking. Gin poles should have at least four guys, with tackles, for easy adjustment. Hoisting may often be done by means of a locomotive running on the tracks of that part of the structure which is already completed. Ropes are used at about ¼ their ultimate strength.

269. Viaducts are usually built from above, by means of an overhead projecting traveler. Sometimes by means of a cableway; but this method is slow In some cases the traveling tower is on the ground, and reaches to the top of the viaduct Or, the viaduct may be erected by means of false-work, or from an existing structure.

270. Long span bridges are usually built upon a platform of false-work or on a row of trestle bents, well braced.

271. Erection. Upon the false-works the lower chords are first laid, as nearly level as may be. The upper chords are then raised upon temporary supports which foot upon the one that carries the lower chord. The upper chords are first placed a few inches higher than their intended positions, in order that the web members may readily be slipped into place. When the web members are in place, the upper chords are gradually lowered until all rests upon the lower chords. The screws are then gradually tightened, to bring all the surfaces of the joints into their proper contact; and by this operation (the upper chord members having the necessary excess of length), the camber is formed, and the lower chords are lifted clear of the false-works; the truss now resting only upon its permanent supports.

272. False-work is ordinarily constructed of hemlock or pine, costing about $20 per 1000 ft. board measure. Allow about $15 per 1000 ft. B. M. for framing, etc. $5 to $15 per 1000 ft. B. M. may usually be obtained for old material ("salvage").

The main members are usually 12 × 12 ins., and the diagonals 3 × 12. Bolts, ¾ inch. Owing to the temporary nature of false-work and to the salvage which may be obtained for it if it is not too badly cut up, it is advisable to use plenty of material of good standard sizes, especially in longitudinal bracing, which may be placed between alternate pairs of bents, forming towers.

273. In soft bottoms, the false-work may rest upon piles, to which the uprights of the false-work may be notched and bolted, or banded. Not less than 4 piles per bent should be used. As many as 24 have been used. Piles should be braced below water-mark. Bents should be built in stories of from 12 to 30 feet each. Connections should be made by means of side pieces or fish-plates.

274. With rock bottom, in a strong current, it may be expedient to sink cribs filled with stone, as a foundation for the false-work.

275. The erection of **cantilevers and suspension bridges** requires much time; but their use is often necessitated by the impossibility of erecting false-work.

276. Renewal of bridges may be accomplished by displacement; either by protrusion, where the new span is skidded longitudinally along the track; by transverse displacement, where both old and new spans are placed on tracks running normally to the bridge; by vertical displacement, either rising or descending; or by pivotal displacement, the old span swinging out about a pivot, and the new span swinging into place about another pivot.

277. Cautions. In erection and renewal, consider dead weight of bridge, effect of impact of current of stream, impact of boats, ice, drift, etc.; especially when floods are to be apprehended, and strains of hoisting tackle

For rigidity, a liberal safety factor must be used. Drift may pile up and form a dam. Trestle bents, in the water, increase the velocity and scour of the current, and may thus cause undermining. False-work may be protected against drift by fender piles. Provide against eccentricities of wind stress. Numerous accidents have shown the expediency of guarding the unfinished truss itself against high winds. All lateral and other wind bracing should be in place, and secured, before the false-works are removed and the trusses allowed to rest upon their final bearings.

Avoid dropping tools, etc. Even very small pieces, falling from a great height, are dangerous to life and even to the bridge. Hooks in tackles are liable to break or to pull out. Travelers should be well guyed and clamped, and carefully watched.

TRUSS SPECIFICATIONS, PAGES 745–764. CONTENTS.

DIGESTS OF SPECIFICATIONS FOR BRIDGES AND BUILDINGS.

(1) Steel railroad, highway and electric railroad bridges.
(2) Combination (wood and steel) railroad bridges.
(3) Steel roof trusses, framework and buildings.

The following Digests of Specifications for Bridges and Buildings are intended primarily to give a general view of the essential features of current practice in such matters, and only secondarily to indicate the practice of any particular company.

(1) DIGEST OF SPECIFICATIONS FOR STEEL RAILROAD AND HIGHWAY BRIDGES.

List of Specifications Used.

A, American Bridge Company,
General Specifications for Steel Railroad Bridges, 1900.
Aa, American Bridge Company,
General Specifications for Steel Highway Bridges, 1901.
B, Baltimore & Ohio Railroad Company,
General Specifications for Railroad and Highway Bridges, Roofs and Steel Buildings, 1901.
C, Cooper, Theodore —,
General Specifications for Steel Railroad Bridges and Viaducts, 1901.
Cc, Cooper, Theodore —,
General Specifications for Steel Highway and Electric Railway Bridges and Viaducts, 1901.
D, Delaware, Lackawanna & Western R. R. Company,
Specifications for Steel Railroad Bridges, October, 1899; revised to July, 1900.
E, Erie Railroad Company,
General Specifications for Bridges, 1900.
G, General practice
Oo, Osborn Engineering Company,
General Specifications for Highway Bridge Superstructures, 1901.
P, Pennsylvania Railroad Company,
Standard Specifications for Steel Bridges, January 1, 1901.
R, Philadelphia & Reading Railway Company,
Specifications for Steel Bridges, 1898; revised February, 1901.
Y, New York Central & Hudson River R. R. Leased and Operated Lines,
General Specifications for Steel Bridges, 1900.

I. GENERAL DESIGN.

Limiting Spans for Different Types.

BEAMS AND GIRDERS.	A ft	Aa ft	B ft	C ft	Cc ft	D ft	Y ft
Rolled beams, solid floor, etc.,	up to 20	up to 40	up to 20	up to 20	up to 40	up to 20	up to 25

Pin trusses,	over 140	over 140	over 120	over 120	over 120	150 & over	200 & over

Riveted trusses,* under 100 ft; pin trusses, over 100 ft, **Oo.**
Depth of truss, min, = one-eighth of span, **Oo.**

* Unfortunately called "lattice girders," **A**; "lattice trusses" and "riveted lattice girders," **C**; "riveted lattice trusses," **D, Y.**

A, Aa, Am B Co; **B,** B & O; **C, Cc,** Cooper; **D,** D L & W; **E,** Erie;

Classification of Highway and Electric Railroad Bridges.

Aa	Cc	
A	A1*	City bridges having buckle-plate floors, and paving on concrete base.
	A2*	City bridges having plank flooring.
B	B*	Suburban or interurban bridges for heavy electric cars.
C	C	Town or country bridges for light electric cars or **heavy loads**
D	D	Country bridges for ordinary highway traffic.
E1	E1	Bridges for heavy electric or motor cars only.
E2	E2	" " light " " "

Camber.

Top chord panels longer than lower chord panels by one-eighth of an inch in 10 ft = 1 in 960, **A, B, C, E, R, Y.**

Highway bridges, three-sixteenths of an inch to every 10 ft, **Cc.**

About three-fourths of an inch in 100 ft = 1 in 1600, **D.**

Sufficient to bring joints of compression chord to a square bearing when truss is fully loaded. Each member built longer or shorter in proportion to the stress to which it is subject under a full dead and a full live load, so that under full loading it will have its normal length, **Oo.**

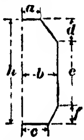
Cross Section of Bridge.

Gage, usually, 4 ft 8½ ins. **Distance, cen to cen of tracks,** 12 to 13 ft.

Width between trusses or girders in deck spans. Pin spans, min, 0.05 span. Riveted trusses (**D**), 10 ft. Plate girders (**G**), 5 to 7 ft. Spans not over 60 ft, 7 ft; 60 to 100 ft, 8 ft; over 100 ft, about one-twelfth of span, **D.** Plate girders (**Y**), over 60 ft, in proportion to height.

Clearance in through spans, on tangents, G.

a	3 to 3½ ft
b	7 ft
c	5 to 5½ ft
d	4 to 6 ft
e	10 to 14 ft
f	1 to 5 ft
h	20 to 22 ft



Minimum Clearance on Curves.
Same min clearance as on tangents, **A;** Ditto for car 74 ft long, 48 ft cen to cen of trucks, 10 ft wide, **B;** Ditto for car 75 ft long, 54 ft cen to cen of trucks. Additional clearance = 0 8 **d** ins on each side; = 1 6 **d** ins between tracks; where **d** = degree of curvature = central angle subtended by a chord of 100 ft, **C;** increase lateral clearance at top of car 2.5 ins for each inch of superelevation of outer rail, **C.** Cen line of bridge bisects middle ordinate and is parallel to chord, **Y.**

Highway Bridges. Headway, 14 ft, **Oo.** For classes A, B, C, and E, min = 15 ft, **Aa, Cc;** for a width of 6 ft over each track, **Aa.** For Class D, 12.5 ft, **Aa, Cc. Horizontal clearance.** Min 14 ins greater than width of roadway between wheel guards, **Aa.** For electric cars, 6 5 ft from cen of track, **Aa;** 7 ft, **Cc.** On curves, provide for a car of 45 ft extreme length, 8 ft wide, 20 ft between truck centers, **Aa.** Width between centers of trusses, min = 0.05 span, **G.**

Tension Members.

In general, hip verticals and one or two panels of lower chord at each end of span are required to be of rigid section, so as to resist both tension and compression.

Angles, used as tension members, must be fastened by both legs, **C, D;** or the section of one leg only will be considered effective, **C.**

Adjustment.
Avoid adjustable members, **A, Aa, D** (**P** except in counters). Avoid

* **Cc,** Classes A and B shall be designed to carry, at any future time, a double track electric railway.

G, gen'l; **Oo**, Osb'n; **P**, Pa; **R**, R'd'g; **Y**, N Y C; **Aa**, **Cc**, **Oo**, H'way.

adjustable counters, **C**, Counter rods and ties in pin spans adjustable, **Y**; screw ends upset, **C, E, Y**, screw threads U. S. Standard, **C, Cc, D, E**; diameter, at base of thread greater than in body of bar by one-sixteenth of an inch, **D**; about 10 per cent, **Y**; 17 per cent, **Oo**.

Rods with welded heads must be of wrought iron, **Oo**. Loops must develop full strength of bar, **Oo**.

Compression Members.

End posts and upper chords have 2 webs, a cover plate on top flange, batten or tie plate, and lacing on bottom flange, **G**

Not more than one plate, and that not thicker than one-half of an inch (in highway bridges three-eighths of an inch), shall in general be used as a cover plate, **C, Cc**. Cover plate must not extend more than 4 ins beyond outer row of rivets, **D**.

Joints between sections spliced on all sides with at least 2 rows of closely pitched rivets on each side of joint, **C**. Abutting surfaces faced **A** (**D, P**, except in top flanges of girders), **E, R, Y**. No reliance on abutting surfaces, **E**.

Lattice Bars.

Width, from 1.5 to 2 5 ins Thickness, in single lattice, one-fortieth, distance between rivets, in double lattice, one-sixtieth, **G**. If over seven-sixteenths of an inch, use angles, **Oo**. Angle with axis of member; in single lattice 60°, double 45°, **G**.

Pitch width of channel + 9 ins, **C, Cc**; 8 × least width of segment, **P, R**.

Double lattice bars riveted together at their intersections, **C, D**.

Batten Plates. (Tie Plates, Stay Plates) Min length generally = from 0.75 to 1 5 × its own width. Min width, 9 ins, or 0 66 × own length, or = least width of member, **Oo**. Min thickness = three-eighths of an inch or one-fiftieth to one-sixtieth of distance between centers of rivets, **G**. Rivet spacing (**D**) max 4 ins cens.

Pin Joints.

Eye Bars. Thickness, min, 0 625 inch, or 0.2 × width of bar, **Oo**. Heads upset, rolled or forged, **A, R**. No welds allowed **A, D**, except (**R**) to form loops of laterals, counters or sway rods, **R**. Upset and die-forged, **Y**. Heads not more than one-sixteenth of an inch thicker than body, **D, P**. Bars annealed, **G**; before boring, **D**. No forge work after boring, **R**. Bars to be placed side by side must be bored at the same temperature, **A, Aa, Y**. Pins must pass through without driving Eye bars working together must be clamped together, and bored at one operation, **Oo**.

Distance between pin-holes max variation, one sixty-fourth to one thirty-second of an inch; or one sixty-fourth of an inch in from 20 to 25 ft, **G**.

Built Tension Members. Net section through pin hole = 1.25 to 1.50 × net section through body of member Net section back of pin hole = 0.75 × net section through pin hole, or = 0 80 to 1 00 × net section through body of member, **G**; proportion for double shear on section from back of pin to end of plate, **Oo**; length of plate back of pin, min, 2 5 ins, **Oo**. Distance, back of eye to back of member, greater than radius of pin, **Y**.

Pin Holes. Clearance between pin and hole, from one-fiftieth to one thirty-second of an inch, **G**.

Pin Plates or Reinforcing Plates. At least one plate on each side must extend not less than 6 ins beyond edge of batten plate, **G**.

Pins. Up to 7 ins diam, rolled, **P**; over 7 ins, forged, **C**.

Diameter, min, from 0.66 × to 0.85 × largest dimension of any of its eye bars, **G**.

Plate Girders.

Min depth; about one-ninth to one-twelfth of span, **G**.

Proportions of Web and Flange. Bending moments resisted entirely by the flanges, shear resisted entirely by the web plate, **C, Cc, R**; except when the web is made in one length or is fully spliced to resist the bending stresses, in which case one-sixth of area of cross section of web plate may be considered effective as flange area, **Oo**.

A, Aa, Am B Co; **B,** B & O; **C, Cc,** Cooper; **D,** D L & W; **E,** Erie

---

One-eighth of gross area of web included in flange, **A, Aa, B;** if length = 90 ft or over, **E;** if length is less than 50 ft, only the cover plate and the horizontal legs of the flange angles are to be included in the flange area, **E,** no part of web included in flange, **C, Cc, D, P, R, Y.**

Web. Thickness, min, three-eighths of an inch, **G;** in highway bridges (**Cc, Oo**), five-sixteenths of an inch.
Total shear, acting on side next to abutment, to be taken as transferred into flange angles within distance = depth of girder, **A, Aa, B, E, Oo, P.**

Web Splices. A plate on each side of web, **G;** at least three-eighths inch thick, **A, B;** at least five-sixteenths inch, or three-fourths as thick as web, and wide enough for 2 rows of rivets on each side of splice, **Oo.**

Stiffeners. Generally required at ends and at points of concentrated load. Intermediate stiffeners required usually when unsupported distance between flange angles exceeds 50 to 60 × web thickness; when shear exceeds $10{,}000 - 75 \times \frac{\text{depth}}{\text{thickness}}$, **C;** in highway bridges when shear exceeds $12{,}500 - 90 \times \frac{\text{depth}}{\text{thickness}}$, **Cc;** when shear exceeds $\frac{20{,}000 \times 12\,t}{1 + \frac{d^2}{3{,}000\,t^2}}$, where t = web thickness, d = distance between flanges, **Oo.**
Spacing usually = depth, or = 5 or 6 ft.

Unit stress, max, $10{,}000 - 45\,\frac{l}{r}$, **C;** in highway bridges, $12{,}000 - 55\,\frac{l}{r}$, where l = length of stiffener, r = its least radius of gyration, **Cc.**
Dimensions of angles usually $3\frac{1}{2} \times 3 \times \frac{5}{16}$ to $5 \times 3\frac{1}{2} \times \frac{3}{8}$.

Flanges.
Unbraced length of flange (compression flange, **C, P**) max = 12 × width **B, P, R, Y;** 16 × width, **A, C, Cc;** 20 × width, **D;** in highway bridges = 20 × width, **Aa,** = 25 × width, **Oo.**
Comp. flange has same gross area as tension flange, **A, Aa, B, C, Cc, Oo, P.**
Cover plates must not extend more than 5 ins, or 8 × thickness of first plate, beyond outer line of rivets, **A, Aa, C, Cc.** If of unequal thickness, the heaviest plates are next the angles, and the lightest outside, **A, Aa, B, C, Cc, Y.** One must extend full length of girder, **B, E.** Others must be long enough to take 2 extra rows of rivets at each end, **C, P.**

Bracing, Riveting, Bearings. See Bracing, Riveted Joints, and Bearings, below.

Beam Girders.

Beams in groups of 2, 3 or 4 for each rail, 10-inch channel separators, about 3 ft apart, riveted to webs, **B.**

Bracing.

Composed of rigid members, riveted, **A, Aa, C, Cc, Y;** members intersect each other, and other members to which they are connected, on common center lines, passing through all centers of gravity. Attachments riveted symmetrically in all directions, **Y.**

For Beam Girders. Ten-inch channel strut at each end; with 2 or 3 beams, angle bracing between girders; with 4 beams, angle struts about 6 ft apart. Connections to have at least 3 rivets, **B.**

Lateral.

B, in through spans. Top bracing; portal struts at ends; intermediate struts as deep as the chords; single angles, $3\frac{1}{2} \times 3\frac{1}{2} \times \frac{3}{8}$, intersecting in each panel, for single track; double angles, latticed, for double track.

B, in through spans, bottom bracing; end bottom strut and intermediate angles, riveted to each other and to stringers at each intersection. Not less than 4 rivets at each intersection and at each end connection.

B, in deck bridges, complete upper and lower systems at each panel.

Oo, bottom end struts in all spans, whether deck or through.

Y, top and bottom lateral bracing in all deck bridges and in all through bridges having sufficient head room. Lower lateral bracing in all through

bridges. Upper system in all stringers framed between and riveted to floor beams where length of stringers exceeds 15 times width of stringer flange.

Y, in deck bridges without metal floor system, upper bracing of cross-struts at each panel point; composed of 4 angles latticed, with same depth as upper chord; stiff diagonals intersecting in each panel and riveted to each other at each intersection

For Plate Girders.

Deck. Between upper flanges, angles with at least 4 rivets at connections. Through; lower lateral bracing of angles, intersecting in each panel, riveted to each other and to stringers at each intersection, **B**.

Lateral bracing angles generally of same size as those in stiffeners, **R**.

Cc, in highway bridges, a buckle plate floor may be considered as the required system of lateral bracing at the floor level.

Sway (diagonal, cross, vibration or wind) and **Portal.**

Proportioned to resist unequal loading of trusses in double track spans, **E**, **R**; end sway bracing to transmit all horizontal forces to abutment, **E**; to carry half the max stress increment due to wind & centrif. force, **A**, **Aa**, **B**, **P**.

In deck spans, at each panel point, **A**, **Aa**, **D**, **E**, **P**, **R**, **Y**.

Overhead bracing in through spans whose depth exceeds 25 ft, **C**, **D**, **P**, **Y**; in highway bridges, 20 ft, **Cc**; 25 ft, **Oo**.

In pony trusses and through plate girders, at ends and at each floor beam or cross strut, **A**, **Aa**, **R**; at every panel point, **D**.

In through and half through plate girders, at each floor beam and at each end, or, if there is a solid floor, not over 8 ft apart, **Y**.

In deck plate girders, rigid cross frames at ends and max 20 ft apart, **Y**; sway frames of at least 4 angles at ends and at points 12 to 14 ft apart, **B**; through, not more than 12 × flange width along top flange, **B**.

Riveted Joints.

Rivet Holes. In I beams, must be drilled, **B**.

May be punched; in steel not over $\frac{5}{8}$ to $\frac{3}{4}$ inch thick, **G**.

Sub-punched one-eighth of an inch smaller, and reamed to one-sixteenth of an inch larger, than rivet, in steel over five-eighths to three-fourths of an inch thick; in connections for floor beams and stringers to main trusses or girders, **E**.

No drifting allowed, **A**, **B**, **C**, **D**, **E**, **R**.

No interchange of pieces after reaming, **D**, **P**.

Hole larger than rivet by one-sixteenth of an inch, **G**.

Die larger than punch by max one-sixteenth of an inch, **G**,

Distance from edge of plate to center of rivet. Min, 1 25 to 1.5 ins, or 1.5 to 2 diams of rivet. Max, 4 to 5 ins, or 8 × thickness of plate, **G**.

Pitch Min = 3 × diam of rivet, general; preferably 4 × diam, **Oo**.

Max pitch in line of stress, 5 to 6 ins, or 16 × thickness of thinnest outside plate connected; normal to stress, 30 to 50 × thickness of thinnest outside plate connected. At ends of compression members (or of built members in tension, **B**); for a length of 1.5 to 2 × width or depth of member, 3.5 to 4 × diam of rivet, **G**.

In plate girders, for rivets connecting web to a top flange supporting the track, max = 3 ins, **R**.

Rivets. Diam generally three-fourths or seven-eighths inch. Heads hemispherical, **G**. Height of head, min = 0.6 diam, **R**.

Driving. Avoid hand riveting. Machines, direct-acting, worked by steam, hydraulic pressure or compressed air, capable of maintaining applied pressure after upsetting, **G**.

Floor.

Floor Beams. Depth, min, = $\frac{1}{8}$ × length, **Y**. In railroad bridges and important highway bridges, riveted to posts of trusses or to webs of plate girders, **G**. Given also a bearing on lower flange of girder or on a bracket, **G**. In default of such bearing, increase number of rivets by 25 per cent, **R**.

Hangers, when permitted, not adjustable, **C**, **Cc**. Hangers made of plates or shapes, **Oo**.

Stringers. Depth, min, = $\frac{1}{8}$ × length, **Y**. In highway bridges, Classes

A, Aa, Am B Co; **B,** B & O; **C, Cc,** Cooper; **D,** D L & W; **E,** Erie;

A1 and A2, of steel; Classes B, C, and E, track stringers of steel; Class D, of wood or steel, **Cc.** In railroad bridges, and preferably in highway bridges, riveted to webs of floor beams and supported by their flanges or by brackets, **B, R.** Value of this bearing neglected in determining number of rivets required, **R.**

Spacing, cen to cen, 6 ft, 6 ins, **A, B, C, D, Y;** 5 ft, **E;** double track, through, generally 6 ft, **R;** single track, 8 ft, **R.**

Trough Floors. Troughs rectangular, built of plates and angles, and riveted to main girders or trusses by angles, and, when practicable, by bracket angles under the lower horizontal plates Gusset plates riveted to girders and troughs at distances of not over 8 ft, **Y.**

Bottom filled with a binder composed of 1 cu ft of clean, sharp gravel, screened to one-fourth of an inch, to 1½ gallons of No. 4 asphalt paving composition or enough to fill voids. Gravel first heated to 300° F and the whole mixed at that temperature, **Y.**

Wooden Floor. Continued over abutments, **A, B, C, R.**

Ties or Floor Beams. Long leaf yellow pine or white oak, **G.**

Width, 8 ins, **A, B;** 9 ins **R.**

Depth, 8 ins, for 7 ft span of tie, to 14 ins for 12 ft, **B;** 12 ins, **R;** 10 ins, **Y.**

Notched down one-half of an inch; max 1½ ins, **B.**

Spacing. Usually 6 ins clear; 16 ins cen to cen, **R.** Every 3d, 4th, or 5th tie fastened to stringer by ¾ inch bolt or lag screw, **G.**

Wooden Joists in Highway Bridges. Width, min 3 ins or 0 25 × depth; spacing, max, 2 to 2 5 ft Ends of joists lap past each other at bearings on floor beams, with 0 5 inch space between them for circulation of air.

Wooden Floor Beams for Electric Railroad Bridges, Classes E1 and E2 Min 6 × 6 ins, spacing max 6 ins, notched down one-half of an inch and secured to girders by three-fourths-inch bolts not more than 6 ft apart. From center of span toward end, so notched (**Cc**) as to reduce camber.

Guard Rails. 6 × 8 ins, yellow or white pine, **G.** Inner face not less than 3 ft 3 ins from center of track, **A;** 3 ft 7½ ins, **B;** 5 ft 4 ins, **Y;** 7 ft 1½ ins apart, clear, **R.** Notched ½ to 1½ ins over ties, **G.** Fastened to every 3d or 4th tie (to each tie, **R**) and at splices by three-fourth-inch bolt or lag screw, **G.** Splices over floor timbers, with half-and-half joints of 6 ins lap, **G.**

Wheel Guards and Curbs in Highway Bridges. Wheel guards 6 × 4 ins, blocked up from floor plank by blocks 2 × 6 ins, 12 ins long, not more than 5 ft apart, bolted to stringers through blocking pieces, three-fourths-inch bolts, **G.** In electric railroad bridges (**Cc**, Class E) guard timbers min 5 × 7 ins, notched 1 inch over floor timber and secured by three-fourths-inch bolt to every third floor timber and at each splice.

Buckle Plates. Min five-sixteenths of an inch thick for roadway, one-fourth of an inch for footwalk, crown 2 ins, for widths of 4 ft under roadway, 5 ft under footwalks. Preferably in continuous sheets of panel lengths. May be pressed or formed without heating.

Bearings on Abutments and Piers.

Permissible load on masonry foundations, max, pounds per sq inch. 400, **A, Aa, P;** 300, **B;** 250, **C, Cc, D, E, R;** dead load, 500; live load, 250, **Y.**

Bed Plates. Of medium steel, **C, Cc.** Min thickness, three-fourths to 1 inch; in highway bridges, one-half of an inch. Max fiber stress 12,000 lbs per sq inch, **E.**

Where ends of two spans rest on one pier, spans are tied together, or have bed plate, three-eighths to three-fourths of an inch thick, continuous under both, **G.**

Sheet lead, one-eighth to one-fourth of an inch thick, between bed plate and masonry, **G.**

Anchor bolts, 1 to 1 25 ins diam, 9 to 12 ins in masonry, **G;** fastened with sulphur, **R;** with cement, **C, Cc, Y.**

Pedestals. Of riveted plates and angles, **C;** or cast steel, **Y.** Base plate and connecting angles, min three-fourths to seven-eighths of an inch thick, **B, C, Y.** 2 rows of rivets in vertical legs, **C, Y.**

G, gen'l; **Oo**, Osb'n; **P**, Pa; **R**, R'd'g; **Y**, N Y C; **Aa**, **Cc**, **Oo**, H'way.

Expansion Bearings. Provide for temperature range of 150° F, **A, C, E, P, R**; for expansion of 1 inch in 100 ft, **D, Y.**

One end sliding, usually in spans less than 60 to 90 ft, **G.**

One end on friction rollers, usually in longer spans, **G**; in all trusses, **Y.**

Hinged bolster at each end, in spans from 80 to 100 ft, **G.**

Rollers rest on bars 3 × 1 inch, spaced 2 ins and riveted to bed plate, **B.** Free ends anchored against lifting and against moving sideways, **C. Y.**

Rollers. Of machinery steel, **C, Cc.** Min diam, 3 to 4 ins, **A, B, D, E, P, R**; 3 ins up to 100 ft span, 1 inch for each additional 100 ft, **C, Y.** Max pressure on rollers, in lbs per linear inch, 700 $\sqrt{d}$, **R**; 1200 $\sqrt{d}$, **A, B, P**; 300 d, **C, D, E**; 600 d, **Oo**; d = roller diam, ins. Length, ins, = 900 $\sqrt{d}$, **Y.**

II. MATERIAL.

Rolled and Cast Steel and Iron.

Rolled steel in superstructures in general.

Cast steel in bed plates in special cases, in machinery of movable bridges.

Rolled iron in loop-welded rods, **P**; in laterals and unimportant members, **R.**

Cast iron in bed plates in special cases and in machinery of movable bridges.

Rolled Steel, Grades.

Soft. In general, in all principal parts.

Medium. In pins, friction rollers, lateral bolts, bearing plates, eye-bars, sliding plates and bed plates; permissibly (**C**) in compression in chords, posts, and pedestals.

Rivet. In rivets.

Machinery. In expansion rollers, **C.**

Rolled Steel. Manufacture.

(See also Digest of Specifications of Internat'l Ass'n for Testing Materials.)

All to be made by open-hearth process.

Slabs for rolling plates are hammered or rolled from ingots of at least twice their cross-section, **A, B.**

Plates up to 36 ins wide rolled in universal mill, **D, R**; or have edges planed, **D.**

Rolled Steel. Manipulation.

Annealing. Eye-bars heated to uniform dark red and allowed to cool slowly, **P**; members worked at blue heat are heated to a uniform bright red (not exposed to direct flame) and allowed to cool slowly, **B.**

Steel must not be welded, **B.** No reliance upon welded steel, **C.**

No work put upon steel at or near blue heat, or between boiling-point and point of ignition of hardwood sawdust, **C.**

Rolled Steel. Shop Work.

Sheared edges of steel thicker than five-eighths inch shall be planed, **B.**

All sheared edges (in medium steel, **D**) shall be planed off to a depth of 0.25 inch, **D, Y**; except web plates of girders over 36 ins deep when covered by flange plates, and fillers where sheared edges are not seen, **D.** Grinding not accepted as equivalent of planing, except for lattice bars, **Y.**

No sharp or unfilleted re-entrant corners permitted, **D, Y.** Where a plate, angle or shape has been cut into, the fillet, as well as the cut, must be finished with sharp cutting tool, or with chisel and file, so that no sign of the punched or sheared edge remains, **D.**

Angles or bent plates, used as end connections on girders, floor beams or stringers, must be accurately fitted, so that when the member is milled to length not more than one-sixteenth of an inch will be taken off these connections at their roots, **D.**

Material bent by punching must be straightened before bolting up, **R.**

Web plates, if buckled, must be cold-rolled to remove the buckles, **D.**

Spliced chord sections must be assembled and strung out in shop in lengths of not less than three sections, and, after being drawn up into contact at

joints and lined up with splice plates in place, the field rivet holes shall be reamed to a fit before taking apart, and the assembled parts, with their splice plates, match-marked, **D.**

Riveted members must have all parts pinned up and drawn together before riveting up, **D.**

In cases of skew work, or of complicated connections, or of a large number of pieces of one and the same kind, the work shall be set up and fitted together in the shop, sufficiently to insure against any misfit, **D.**

Abutting surfaces at ends of sections of compression members, and ends of members to be framed together, are usually required to be faced.

Rolled Steel. Requirements.

See also Digest of Specifications of International Association for Testing Materials.

TENSILE TESTS.

Specimens of Medium, Soft and Rivet Steel. For tests of full size eye-bars see below.

Ultimate Strength, u, and Elastic Limit, el, in thousands of lbs per sq inch. Elongation, s (stretch), and reduction of area, a, in percentages of original dimensions. Elongation measured in a length of 8 ins

	Medium or "Pin" Steel.				Soft or "Bridge" Steel.				Rivet Steel			
	u	el	s	a	u	el	s	a	u	el	s	a
A, Aa ..	60–70	0.5 u	22	..	52–62	0.5 u	25	..	48–58	0.5 u	26	..
B	..	..	..	..	58–63	30	25	..	51–56	27	26	..
C, Cc ...	60–68	0.5 u	22	..	54–62	0.5 u	25	..	50–58	0.5 u	26	..
D	62–70	0.5 u	22	..	54–62	0.5 u	26	..	48–56	0.5 u	28	..
E ...	..	..	..	..	56–64	0.58 u	27	45	..	..	..	..
Oo ..	60–70	35	22	..	52–62	32	25	..	50–60	30	26	..
P	62–70	33	17	40	52–62	28	25	50	48–56	28	28	56
R ...	60–68	0.5 u	20	..	52–60	{ 0.5 u / 28 }	25	..	48–56	28	28	..
Y	62–70	0.6 u	25	45	56–64	0.6 u	26	50	48–56	..	28	55

Specimens from metal over five-eighths of an inch thick, el = 0.56 u, **Y.**
" " eye-bars, same requirements as for medium steel, **D.**
" " " u = 63, **B.**
" " " over 1.5 ins thick, deduct from el 1 for each one-eighth of an inch; el, min = 20, **C.**
" " " and pins u = 62–70, l = 0.6 u, s = 25, a = 45, **Y.**
" " pins, s = 15, **C, Cc.**
" " " (medium, soft or rivet) s, 5 per cent less, **A.**
" " " (soft) s = 20, **B.**
" " " and rollers, s = 10, **D.**
" " rollers and bearing plates, u = 70–78, s = 22, **Y.**

BENDING TESTS.

In medium steel, specimen to bend through an angle of 180° around a bar of diam = 1 to 1½ × thickness of specimen, without showing fracture on outside of bend; in soft and rivet steel, to bend flat upon itself.

NICKING TEST.

When nicked and bent around a bar of diam = thickness of rod, rivet steel shall show a gradual break and a fine, silky, homogeneous fracture, **D.**

DRIFTING TEST.

Center of hole as in ordinary practice, or 1.5 to 1.87 ins or 2 diams from edge of plate; enlarge to 1.25 to 1.50 diam, **G.**

G, gen'l; **Oo**, Osb'n; **P**, Pa; **R**, R'd'g; **Y**, N Y C; **Aa**, **Cc**, **Oo**, H'way.

ANGLE TEST.

Angles of all thicknesses must open flat. Angles not over one-half of an inch thick must bend shut, cold, under hammer blows without sign of fracture, **B**.

TEST PIECES.

Minimum section, usually one-half sq inch. Length, min, 8 to 12 ins Tests are usually required for each melt or blow.

TESTS OF FULL SIZE EYE-BARS.

	Ultimate lbs per sq inch min	Elastic limit lbs per sq inch min	Elongation per cent min
A, Aa	5,000 less than small specimen		10 between necks
B	55,000	0.5 ult	12 between necks § 10 between necks ‖
C, Cc	56,000		10 between necks
D	58,000	30,000	12 in 10 ft
E			15
Oo	55,000		12.5 in 15 ft
P	48,000	27,000	14¶ in 10 ft
R	58,000 * 56,000 †	0.5 ult	13 between necks 10 between necks
	48 000 ‡	27,000	15 between necks
Y	58,000	33,000	10 in 20 ft

In general not over 4 per cent of total number of bars in bridge will be tested, **R**; at least 4 per cent, and not less than 3 bars, **B**.

75 per cent of fracture must be silky, the remainder fine granular, **R**.

Break in head shall not be cause for rejection—

(a) if bar develops 10 per cent elongation (12.5 per cent in 15 ft, **Oo**) and the required ultimate strength (ultimate 56,000, **C**, 55,000, **Oo**) and if not more than one-third of all the bars tested break in the head, **A, C, Oo**.

(b) if bar stretches 14 per cent and if a second bar breaks in body and the average stretch of the two bars is not less than 16 per cent, **P**.

Company pays for bars which meet requirements, less scrap value, **G**.

TESTS OF COMPLETED STRUCTURE.

Specified loads, or their equivalent, passed over structure (in railroad bridges at a speed of not over 60 miles per hour, and brought to a stop at any point by means of air or other brakes) or maximum load rested upon structure for 12 hours. After test, structure must return to its original position and must show no permanent change in any part, **C**.

COMPOSITION

Phosphorus, max percentage.
In acid steel, 0.06 to 0.08; in basic steel, 0.04 to 0.06; in castings 0.08.
Sulphur, max percentage, 0.04 to 0.06.

MAXIMUM PERMISSIBLE VARIATION FROM SPECIFIED CROSS-SECTION OR WEIGHT.

2.5 per cent, **G**, except in extra wide plates, **D**, **Oo**, **P**.
In plates over 40 ins wide, in proportion to width, up to 5 per cent in plates 90 ins or wider, **D**.

1.5 per cent; where plates 36 ins and wider form 40 per cent of total, 2 per cent in excess, **Y**.

Long plates, ¼ inch out of line in 20 ft, ½ inch in 40 ft, **R**.

Shapes or plates, 3 per cent short in thickness; plates 80 ins wide, 5 per cent, **R**.

---

* † Medium steel. * Bars not over 10 sq ins. † 20 sq ins. Proportional values for intermediate areas. ‡ Soft steel. § In bars not longer than 20 ft between necks. ‖ In bars longer than 20 ft between necks. ¶ Max. 16.

A, Aa, Am B Co **B,** B & O; **C, Cc,** Cooper; **D,** D L & W; **E,** Erie

Steel Castings.

Manufacture. Open hearth, **A, Aa, D, P, Y;** acid, **Y;** annealed, **P R, Y.** Carbon, per cent, 0 25 to 0.40, **G.**
Phosphorus, per cent, max, 0.08, **B, Y.**

TENSILE TESTS.

	Size of test piece, ins.	Ultimate strength, lbs per sq inch, min.	Elastic limit, lbs per sq inch, min.	Elongation per cent, in 2 ins min.	Reduction of area per cent
C, D, E, P, R..	½ square or ¾ round	65,000 to 70,000	33,000 or 0.5 ult	10 to 15	20, **P**
Y	¾ round about 6 long	(a) 55,000 to 65,000	...	20	
		(b) 72,000 to 80,000	0.5 ult	15	25

BENDING TEST.

Y (a), for general purposes, bed plates, pedestals, etc , to bend 90°, to a radius = diameter of test piece.
Y (b), for drawbridge rollers, etc.

Rolled Iron.

Requirements in Osborn's specification for highway bridges, **Oo.** Made from puddled iron or rolled from fagots or piles of No. 1 wrought iron scrap, alone or with muck bar. Tensile strength, min, 48,000 lbs per sq inch (50,-000, **R**); yield point, 25,000 lbs per sq inch (26,000, **R**); elongation, 20 per cent in 8 ins; in sections weighing less than 0.654 lb per lineal ft, 15 per cent. Specimens cut from bar as rolled must bend through an angle of 180° under a succession of light blows, when nicked and bent, fracture shall be generally fibrous and free from coarse crystalline spots; not over 10 per cent of the fractured surface shall be granular; specimens heated bright red shall bend through an angle of 180° under a succession of light blows not delivered directly on the bend; must not show red-shortness. In flat and square bars, one-thirty-second of an inch, in round iron 0.01 inch, variation either way in size will be allowed, **Oo.**

Cast Iron.

Tough gray iron, **A, D, E, R;** unless otherwise specified, **A, R.**
Transverse strength. Bar 1 inch square, 12 ins span, to bear 2,500 lbs, center load. Must deflect 0 15 inch before rupture, **G.** Bar 1 inch square, 4.5 ft span, to bear 500 lbs center load, **E, R.**

Phosphor Bronze.

1 inch cube, under compression, elastic limit, 20,000 lbs. Under 100,000 lbs, permanent set max one-sixteenth of an inch, **B.**

Timber.

Sap wood not allowed in more than 10 per cent of the pieces of one kind, and no piece will be accepted showing sap covering more than 0 25 × the width of the piece on any face at any point, or more than half the thickness of any plank at its edge, at any point, **Oo.**

III. LOADS.

1. Vertical Loads.

(Dead and Live Loads and Impact.)

Dead Loads in Steam Railroad Bridges.

Dead load = weight of metal + n lbs per lineal ft of track, **C, D, E, R, Y.** n = 400, **C, D, E**; n = 500, **R**; n = 620, **Y.**
Timber taken at 4 5 lbs per ft, B M, **G.** Ballast, 110 lbs per cu ft, **C.**
Rails, splices, and joints taken at 100 lbs per lineal ft of track, **A, B, C.**
Rails, splices, guard rails, etc, at 160 lbs per lineal foot of track, **P.**
Two-thirds of dead load assumed to be carried by loaded chord, **Y**; in spans less than 300 ft, **B**; in longer spans calculate distribution, **B.**

Dead Loads in Highway and Electric Railroad Bridges.

Iron, 3 33 lbs per lineal ft of bar 1 sq inch **area, Oo.**
Steel, 3 40 " " " " " " 1 sq inch **area, Oo.**
Timber per ft board measure, 4, **Aa**; creosoted, 5, **Oo**; oak, 4 5, **Cc, Oo**; other hard woods, 4 5, **Cc**; yellow pine, 4, **Oo**; spruce and white pine, 3.5, **Cc**; white pine and cedar, 3, **Oo.**
Concrete, etc, lbs per cu ft, 130, **Aa**; stone concrete, 125, **Oo**; cinder concrete, 100, **Oo.** Stone, 150, **Oo**, granite, 160, **Aa.**
Brick, 150, **Aa**; 125, **Oo**; sand, 100, **Oo.** Asphalt, 130, **Aa**; 90, **Oo.**
Rails, fastenings, splices and guard timbers, 100 lbs per lin ft of track, **Aa.**

Live Loads for Steam Railroad Bridges.

THEODORE COOPER'S STANDARD LOADING.

The No. (27 to 50) following the letter E (Engine) in the class designation gives the load, d, on one pair of drivers, in thousands of pounds. In each class, $d = 2b = 40t \div 26 = 10\ U$. Since these ratios are constant for all classes, the stresses, due to any class, are proportional to the class number. The weight of metal, in bridges, is, in each class, about 10 per cent greater than in the class next lighter.

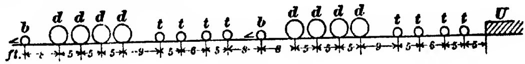


Fig. 1.

TWO CONSOLIDATION LOCOMOTIVES, WITH THEIR TENDERS AND TRAINS.

Class	Load in lbs. on one pair of wheels for each track. Truck (bogie) b	Driver d	Tender t	Train load, lbs. per lin ft. U.
E 27	13,500	27,000	17,550	2,700
E 30	15,000	30,000	19,500	3,000
E 35	17,500	35,000	22,750	3,500
E 40	20,000	40,000	26,000	4,000
E 50	25,000	50,000	32,500	5,000

A, Cooper's loading.
B, Cooper's Class E 50, unless otherwise specified
C, See above.
Y, Cooper's Class E 40.
D, E, P, R, spaces differing slightly from Cooper's. **Loads as below.†**

	b	d	t	U.
D	22,000	50,000	28,000	4,500
E	15,000	35,000	23,000	4,000
P	21,000	44,000	30,000	5,000
R	19,200	{43,200 / 48,000}†	{24,600 / 27,000}†	4,800

† Driver and tender axles unequally loaded. **R.**

A, Aa, Am B Co; **B,** B & O; **C, Cc,** Cooper; **D,** D L & W; **E,** Erie:

ALTERNATIVE LOADINGS.

Use Fig. 1 or the alternative, Fig. 2 or 3, whichever gives the greater stresses.

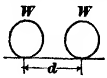

Fig. 2.

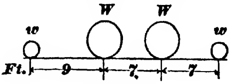

Fig. 3.

Load on one pair of wheels.

Fig. 2. { d = 6 ft; W = W = 50,000 lbs, Above E 40, 60,000 lbs, **C.**
d = 7 ft; W = W = 65,000 lbs, **D.**
d = 7 ft; W = W = 60,000 lbs; U = 4,500 lbs per lin ft, **Y.**

Fig. 3. W = W = 66,000 lbs; w = w = 30,000 lbs, **R.**

Add 30 per cent in figuring floor beams, stringers, hangers, suspenders, and other floor connections. Add 0 to 30 per cent for spans from 100 ft down to 25 ft, **D.**

ON CURVES.

Distribution of live load between the two trusses.

$W = P \frac{m + b}{2 b}$; where W = proportion of live load borne by the outer truss; P = live load at panel considered; m = middle ordinate of entire curve on span; b = dist betw cens of trusses. Make both trusses alike, **B, Y.**

SPECIAL LOADINGS.

For rivets connecting upper flange angles with web in deck girders carrying the floor directly on the top flanges, and in deck spans with wooden floor beams, when distance between trusses exceeds 6 ft, 50,000 lbs on one pair of drivers, distributed equally over three ties or floor beams, **P.**

For floors, the load on a single pair of engine wheels distributed over 4 ties, **B;** over 3 ties, **C.** For trough floors, 60,000 lbs on one pair of wheels, distributed over two troughs, **Y.**

THREE-TRUSS BRIDGES.

In double-track deck spans, all three trusses of equal strength, **C.**

In plate girder bridges of more than one track, center girder figured for 0.75 × the live load, **E.**

FUTURE INCREASE OF LIVE LOADING.

Only 70 per cent (50 per cent, **R**) of the dead load shall be considered effective in counteracting live load stress, **A, R.** Use 1.5 × live load, **E.**

"That the heavier of these engines (see 'C,' under 'Standard Loading,' above) is close to the possible maximum, considering the limitations of the permissible cross-section of existing railroads and the mechanical details of design and proportions, is not improbable. That the economical tendency toward heavier and heavier engines will in the near future reach the heavier class E 50 upon the most important roads is to be expected. The cars will also follow the same tendency for many kinds of traffic, as experience justifies the advance. There are now in use self-dumping coal cars of a nominal capacity of 100,000 pounds, which have, on four axles, a total load of 146,000 pounds (10 per cent increase over nominal capacity) on a wheel base, for two adjacent cars, of 17 ft, 2 ins. These cars on all ordinary bridges produce strains equivalent to those of E 33."—Theodore Cooper.

Members subject to reversal of stress must be so designed that a live load n per cent greater than that specified shall not increase their unit stresses more than n per cent. n = 25, C; 50, B; 100, P.

G, gen'l; **Oo**, Osb'n; **P**, Pa; **R**, R'd'g; **Y**, N Y C; **Aa**, **Cc**, **Oo**, H'way.

Live Loads for Highway and Electric Railroad Bridges.

Aa, (Am. Bridge Co.) and **Cc**, (Theo. Cooper)	For the Floor and its Supports.			For the Trusses.			
	Concentrated.		Uniform (c).	Per lin ft of single track. (Proportionally for intermediate spans.)		Per sq ft of remaining floor.	
Class.*	Wagon (a), tons	Car (b) on each track, tons	Per sq ft, lbs	Spans up to 100 ft, lbs	Spans 200 ft and over, lbs	Spans up to 100 ft, lbs	Spans 200 ft and over, lbs
A	24	..	100	1,800	1,200	100	80
B	12 or	24	100	1,800	1,200	80	60
C	12 or	18	100	1,200	1,000	80	60
						Up to 75 ft

(a) On two axles, 10 ft cens (and, **Aa**, 5 ft gage); in classes A, B, and C, assumed to occupy a width of 12 ft in single line (or, **Cc**, 22 ft in double line) on any part of the roadway.

(b) On two axles, 10 ft centers.

(c) In classes A, B, and C, on remainder of floor, including footwalks. In class D, on total floor surface.

Oo. Osborn Engineering Co. Highway. May specify any combination of the following loadings, according to character of bridge and of load.

Uniform loads, lbs per sq ft. For spans up to 150 ft, 100 on roadway and 80 on sidewalks, or 80 on both. For spans over 150 ft, 80 or 60 on both.

A steam road roller; axles 11 ft apart, forward roll 4 ft face, two rear rolls 5 ft cens and each 20 ins face. 15,000 or 9,000 lbs on forward roll and 10,000 o 6,000 lbs on each rear roll;

A horse roller, 12,000 lbs on roll, 5 ft face;

A wagon load, 10,000 lbs on two axles, 8 ft apart, 5 ft gage;

Two electric cars on each track; Fig. a

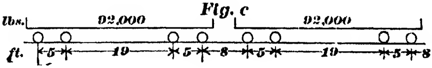
A train of electric cars on each track; Fig. b.

A train of coal cars of 60,000 lbs capacity; Fig. c.

Fig. a

Fig. b

Fig. c



*Class A, city bridges.
" B, suburban or interurban.
" C, heavy country highway.
Class D, ordinary country highway.
" E1, heavy electric railway only
" E2, light electric railway only

A, Aa, Am B Co; **B,** B & O; **C, Cc,** Cooper; **D,** D L & W; **E,** Erie;

FUTURE INCREASE OF LIVE LOADING. HIGHWAY.

In electric railroad bridges, Class E, only 70 per cent of dead load stress to be considered as effective in counteracting the live load stress, **Aa.** For bridges carrying electric or motor cars, counters so proportioned that a future increase of 25 per cent in the specified live load shall not increase the unit stress more than 25 per cent, **Cc.**

Impact.

$I = S \frac{300}{l + 300}$; where I = impact stress to be added to the live load stress; S = calculated max live load stress; l = length in feet of loaded distance which produces the maximum stress in the member, **A.**

$I = S \left(0.1 + \frac{56.25}{l \times 62.5}\right)$, Mr. G. Bouscaren, C. E.

In Highway Bridges; I = 25 per cent of live load stresses **Aa;** $I = L^2 \div (L + D)$, where L and D = live and dead load stresses, **Oo.**

2. Horizontal Forces.

(Drag, Centrifugal and Wind.)

(a) Longitudinal.

Drag. In bridges for steam and electric railroads, provide for a longitudinal force, at the rails, = 0.2 of the max live load. In double track (**Y**), provide for trains moving either way.

(b) Transverse.

(1) Centrifugal Force.

F = centrifugal force; W = weight of train on bridge; d = degree of curvature = central angle subtended by a chord of 100 ft; v = velocity in miles per hour; c = a coefficient.

A, F = c d W. For d up to 5°, c = 0.03. Deduct from c 0.001 for each degree over 5°. Train on each track.

B, R, F = 0.02 of the live load for each deg of curvature. **B,** up to 5°. Deduct 0.001 for each degree over 5°.

C, F, computed for v = 60 — 3 d on steam railroads, = 40 on electric railroads; force acting 5 ft above base of rail.

D, v = 60.

E, F = force due to that uniform load which would produce the max specified live load bending moment on span; v = 60.

Y, $F = W v^2 d \div 85{,}666$. Up to d = 4°, v = 60. For d over 4°, v = 60 — 2 d. Max train load on each track.

(2) Wind.

(a) ON RAILROAD BRIDGES.

Wind pressure, in lbs per sq ft, = w; in lbs per lin ft = W.

w = either 30 lbs per sq ft on exposed surface of trusses and floor and on that of a train of 10 ft average height, beginning 30 ins above rail base; or 50 lbs per sq ft on exposed surface of trusses and floor; whichever gives the greater stresses, **A, P.**

In truss spans over 200 ft & in plate girders, w = 30 lbs per sq ft of exposed surf of 1 girder and floor, + W on train for lower chord, as below, **B.**

W = L + U. L = pressure in lbs per lin ft on loaded chord, U on unloaded chord. W includes both wind on bridge and wind on train.

Wind on bridge. L = U = 150, **B, C,*** **D, R;** = 200, **E.**

L = 200, on double track 300, acting 8 ft above rail top;
U = 150, on double track 225, acting at cen of chord; } **Y.**

Wind on train. L = 300, **B, D, R,**† **Y;** = 450, **C,**‡ = 400, **E.**

---

* In spans over 300 ft, add to U 10 lbs for each additional 30 ft, **C.**
† Acting 7.5 ft above rail, **R.**
‡ Acting 6 ft above rail base. Includes lateral vibrations of trains.

G, gen'l; **Oo**, Osb'n; **P**, Pa; **R**, R'd'g; **Y**, N Y C; **Aa**, **Cc**, **Oo**, H'way.

A. Wind stress, Sw, in any truss member, **C** (main truss member, **D**; chord or end post, **R**), need be considered only (1) when Sw exceeds 30 per cent, **C** (25 per cent, **D**, **R**), of max stress, S, due to dead and live loads. Then increase section to bring Sw within limit, **C**, **D**, **R**. (2) When Sw, alone or in combination with temperature stress, can balance or reverse S, **C**.

Anchorage. In determining the requisite anchorage for the loaded structure, the train is assumed to weigh 800 lbs per lineal foot, **A**, **B**, **C**, **P**; 600 lbs per lineal foot, **R**.

(b) ON HIGHWAY AND ELECTRIC RAILROAD BRIDGES.

Either 30 lbs per sq ft on the exposed surface of all trusses and floor, + 150 lbs (180, **Oo**) per lineal foot of a train covering the span; or 50 lbs per sq ft on the exposed surface of all trusses and floor; whichever gives the greater stresses, **Aa**, **Oo**.

On each chord, 150 lbs per lin ft, of span, due to bridge, and on the loaded chord 150 lbs per lin ft of span additional due to train. For spans exceeding 300 ft, add 10 lbs on each chord for each additional 30 ft, **Cc**.

Wind stresses (in truss members, **Cc**; in chords and end posts, **Oo**) to be provided for only when the wind stress exceeds 25 per cent of the max dead and live load stresses (of the sum of all other stresses, **Oo**), or when the wind stress (alone or in combination with temperature stress, **Cc**) can (neutralize or, **Cc**) reverse the stress in the member, **Cc**, **Oo**.

IV. STRESSES AND DIMENSIONS.

Effective Span and Depth.

In pin spans, span and depth are measured between centers of pins. In riveted trusses, the span is measured between centers of end bearings, and the depth between centers of gravity of chord sections. In plate girders the span is measured between centers of end bearings, and the depth between centers of gravity of flange areas or over backs of flange angles, whichever is the less. In floor beams the span is measured between centers of trusses, and in stringers between centers of floor beams, **G**.

Limiting Unit Stresses.

Tension.

Net Section. The net section of any tension member or flange is determined by a plane cutting the member square across at any point. The greatest number of rivet holes which can be cut by the plane, or come within an inch of the plane, is deducted from the gross section, **B**. The rupture of a riveted tension member is considered equally probable, either through a transverse line of rivet holes, or through a diagonal line of rivet holes where the net section does not exceed by 30 per cent the net section along the transverse line, **C**, **Cc**.

In deducting rivet holes for net section, their diameter is taken at one-eighth of an inch greater than that of the cold rivet, **G**; for countersunk rivets (**Oo**), one-fourth of an inch greater.

Maximum permissible tensile stresses, in lbs per sq inch.

		Medium Steel	Soft Steel
A, **Aa**,	Under vertical forces only or horizontal forces only	17,000	15,000
	Under vertical and horizontal forces combined	21,000	19,000

B, For "Bridge" (soft) and Rivet Steel, same as Medium Steel under **A**.

D. For soft steel:	For dead load;	live load.
Eye-bars	14,000	9,000
Built sections	12,500	8,500
Counters		8,500

	For dead and live load
Hip suspenders, floor beam hangers, members subject to sudden loading	7,500
Tension flanges of plate girders and rolled beams	9,000
Bracing	12,000

A, Aa, Am B Co; B, B & O; C, Cc, Cooper; D, D L & W; E, Erie

Main members of trusses, flanges and webs of girders and floor beams for double track, floors and girder flanges with ballast floor, add 10 per cent

For medium steel, add 10 per cent.

E. $8{,}000\left(1+\frac{\text{min stress}}{\text{max stress}}\right)$.

Oo. (Highway Bridges.) Medium steel, 22,000; soft steel, 20,000; wrought iron, 18,000

P. M = max calculated stress in member
m = min " " "

Let $r = \frac{m}{M}$; let $k = \frac{1-r}{1+r}$. Then M (1 + k) shall not exceed 15,000

Long hip verticals must have 25 per cent excess strength; short floor beam hangers 50 per cent excess, P.

Y. Soft steel. Chords and web members of trusses, and flanges of plate girders, floor beams and stringers.

Dead load and drag.................................. 16,000
Live load and centrifugal force........................... 8,000

MAXIMUM STRESSES IN TIMBER, LBS PER SQ INCH.

For Highway Bridges, Oo.	Transverse loading	End bearing	Short column *	Bearing across fibre	Shear along fibre
White oak	1,400	1,300	1,000	550	300
Long leaf pine	1,600	1,300	1,000	350	200
White pine	1,100	900	700	200	150
Hemlock	950	850	650	200	100

Extreme fibre stress, in floor beams, max, yellow pine and white oak, 1,200 lbs per sq inch; white pine and spruce, 1,000, Aa, Cc.

Compression.

p = permissible working stress in compression member, in lbs per sq inch.
f = generally the permissible stress in tension member, in lbs per sq inch.
a = a coefficient.
L = length of piece, in ins, between cens of connections.
r = least radius of gyration of cross-section of member, ins.

$$p = \frac{f}{1+\frac{L^2}{r^2 a}}$$

		f	a
Aa.	In medium steel	17,000	11,000
	In soft steel	15,000	13,500
B.	In soft steel	17,000	11,000
C.	See below.		

	Dead load f	Dead load a	Live load f	Live load a
D.	12,000 to 12,500	18,000 to 24,000	8,000 to 8,500	18,000 to 24,000*

E. $f = 8{,}000\left(1+\frac{\text{min stress}}{\text{max stress}}\right)$; a = 36,000 with both ends fixed; a = 24,000 with one end fixed; a = 18,000 with both ends hinged.

Oo. (Highway Bridges.) f = 22,000 for medium steel, 20,000 for soft steel, 18,000 for wrought iron; a as in E, above.

P. f = 15,000; a = 13,500.

R. $f = 6{,}500\left(1+\frac{\text{min stress}\dagger}{\text{max stress}}\right)$; f max = 8,000; a = 40,000 with flat ends; a = 20,000 with pin ends.

When one end is pinned, p = mean of values derived as above.

For angle iron struts, see below.

*Length not over 12 × least side. †Min stress = dead — live load stress

G, gen'l; **Oo**, Osb'n; **P**, Pa; **R**, R'd'g; **Y**, N Y C; **Aa**, **Cc**, **Oo**, H'way.

Y. Soft steel in chords and web members:

	f	a
For dead load and drag	16,000	18,000
For live load and centrifugal force	8,000	18,000

C, Cc. $p = M - c\frac{L}{r}$.

For medium steel in stationary structures:

	Dead load M	Dead load c	Live load M	Live load c
Chord segments, stiffeners.	20,000	90	10,000	45
For highway bridges	24,000	110	12,000	55
End and other posts	17,000 to 18,000	90 to 80	8,500 to 9,000	45 to 40
For highway bridges	20,000 to 22,000	90 to 80	10,000 to 11,000	45 to 40
Lateral struts, rigid bracing for railroad and highway bridges	13,000	60	8,666	40

For soft steel, deduct 15 per cent; for movable structures, deduct 25 per cent.

R. Angle iron struts.

With flat ends, $p = 9{,}000 - 30\frac{L}{r}$; with pin ends, $p = 9{,}000 - 34\frac{L}{r}$.

In lateral and cross struts, add 30 per cent.

Length of compression members, max. = 40 to 45 diameters, or 100 r to 120 r. In highway bridges, 120 r to 140 r, **Aa**; 100 r to 120 r, **Cc**; 125 r to 150 r, **Oo**, where r = least radius of gyration.

Unsupported width (distance between rivets) of plates subject to compression, max = 45 × thickness, **Oo**; 30 × thickness, **C, Cc, D**; in cover plates of top chords and end posts, 40 × thickness, **C, Cc, D**; or, if a greater width is used, effective section shall be taken as 40 × thickness, **C, Cc.** Distance between supports in line of stress, max = 16 × thickness, **Oo.**

Timber columns, whose length exceeds 12 × their least sides, in highway bridges, **Oo.**

$$\text{Max unit stress} = \frac{C}{1 + \frac{L^2}{1{,}000\,d^2}}$$

where C = 1,000 lbs per sq inch for white oak and long leaf pine, 700 for white pine, 650 for hemlock; L = length of column, between supports, ins; d = least side, ins, **Oo.**

Alternating Stresses.

Total sectional area of member to be made = sum of areas required for both stresses, **A, B.**

Area sufficient to resist either stress plus 0 8 (0 6, **R**; 1 0, **Y**) × the lesser stress, **C, Cc, D, R, Y.**

Permissible working stress, in lbs per sq inch:

$$a = 8{,}000\left(1 - \frac{\text{max stress of lesser kind}}{2 \times \text{max stress of greater kind}}\right), \textbf{ E.}$$

M = max calculated stress of greater kind,
m = max calculated stress of lesser kind,
Let $r = \frac{m}{M}$. Let $k = \frac{2 + r}{2 - r}$. Then M (1 + k) shall not exceed 15,000 lbs per sq in. } **P.**

IN BRIDGES FOR HIGHWAYS AND FOR ELECTRIC RAILROADS.

In Classes A, B, C, and D, members proportioned for that stress which requires the larger section. In Classes E 1 and E 2, make sectional area = sum of areas required for the two stresses, **Aa.** Members designed to resist either stress and given 25 per cent excess of strength in their joints and connections, **Oo.**

A, Aa, Am B Co; **B,** B & O; **C, Cc,** Cooper; **D,** D L & W; **E,** Erie

Shear and Bearing Stresses.

Shear in web plates, max, lbs per sq inch. 10,000, **B;** 4,000, **E;** 5,000, **R;** 13,000, **P;** in medium steel, 10,000. **A, Aa;** in soft steel, 9,000, **A, Aa;** across grain, 6,000, **D;** with grain, 5,000 (net section), **D;** dead load, 10,000, **Y;** live load, 5,000 (gross section), **Y.**

Shear and Bearing on Rivets, Bolts and Pins. Maximum, in lbs per sq inch

	Shear		Bearing	
	Medium	Soft	Medium	Soft
A, Aa, B	12,000	11,000	24,000	22,000
C	9,000	9,000	15,000	15,000
Cc	10,000	10,000	18,000	18,000
Oo	10,000	10,000	22,000	20,000
D, R	7,500	7,500	12,000	12,000

Y, Shear = 0.75 S ; bearing = 1.50 S. S = permissible unit stress in tension.

In field riveting, increase number of rivets 25 per cent, **A, Aa, B, Oo, P;** if machine driven, 10 per cent, **A, Aa, P;** in stringers and floor beams, one-third, **P.** Take 0 66 to 0 80 × stress as above, **C, Cc, D, R, Y.**

In floor connections, use 0.8 × stresses as above, **C, Cc;** add 20 per cent to number of rivets, **Y.**

In wind and sway bracing, use 1.25 to 1 5 × stresses as above, **C, Cc, D, R.**

Rivets with countersunk heads taken at 0.75 × value of rivets with full heads, **P.**

Bearing, on phosphor bronze disks, 5,000 lbs per sq inch, **B.**

Bending Stresses.

Stress in extreme fibres, under bending moments, max, lbs per sq inch.

In pins and bolts, 25,000, **B;** 18,000, **C;** 20,000, **Cc;** 15,000, **D, R;** 16,000, **Y;** in pins, closely packed, 25,000, **Oo;** in medium steel, 25,000; in soft steel, 22,000, **A, Aa, P.** Centers of bearings of strained members taken as points of application of the stresses, **A, Aa, R.** Applied forces considered as uniformly distributed over the middle half of the bearing of each member, **C, Cc.** Bending calculated from distances between centers of bearing, **Oo.**

In rolled beams and channels, 14,000, **P.**

In wooden floor beams, 1,000, **A, B, C, P.**

Compound Stresses.

Compound (axial and bending), maximum, lbs per sq inch.

In end posts of through spans, dead + live + wind + bending, max = 15,000, **R.**

Proportion the member to resist sum of direct stress plus 0.75 bending stress, **A, Aa, B, P, R.** Max = $\dfrac{8,000}{1 + \dfrac{L^2}{40,000\ r^2}}$, where L = length, ins; r = least radius of gyration, ins.

If pins are out of neutral axis of section, max must include the additional stress due to the eccentricity, **R.**

Bending moment at panel points assumed equal and opposite to that at the center, **A, Aa.** If fibre stress due to weight of member alone exceeds 10 per cent of the allowed unit stress on such member, the excess must be considered in proportioning the areas, **C, Cc, R.**

Minimum Dimensions.

Minimum thickness of plates, in railroad bridges, three-eighths of an inch for main members, five-sixteenths of an inch for laterals; in highway and electric railroad bridges, five-sixteenths to one-fourth of an inch. Min diam of rod, three-fourths of an inch, **Oo.** Rods and bars, min section, 1 sq inch, **D, R;** counters 1.5 sq ins, **D, P.** Posts, in pin spans, min width 10 ins, **A.** In posts of through spans, channels min 10 ins, **R.** Angle, min, 3.5 × 3 × five-sixteenths, **B.**

G, gen'l; **Oo**, Osb'n; **P**, Pa; **R**, R'd'g; **Y**, N Y C; **Aa**, **Cc**, **Oo**, H'way

V. PROTECTION.

At Shop. After removing loose scale and rust; 1 coat pure boiled linseed oil, **A, Aa, B, D, E, P, R**; raw linseed oil, **C, Cc**; with 10 per cent in weight of lampblack, **D**; standard red lead paint.* **Y.**

Inaccessible Parts. 2 coats iron ore paint in pure linseed oil, **A, Aa, B, C, Cc, E, R**; standard red lead paint,* **Y**; 1 coat, **D**; 1 heavy coat red lead in raw linseed oil, **P**; 2 coats, 18 lbs red lead in 1 gal boiled linseed oil, **Oo.**

Finished Surfaces. Coated with white lead and tallow. General.

Surfaces in Contact. Painted before joining, **A, Aa, B, C, Cc, R, Y**; with 2 heavy coats red lead in raw linseed oil on each surface, **Y.**

After Erection. 2 additional coats of paint in pure linseed oil, **A, Aa, B, C, Cc**; 2 coats of paint, of different colors, **R**; 2 heavy coats asphaltum varnish, **Y.**

At least 48 hours allowed for drying of each coat, **Y.**

Columns. etc., for 5 ft above surface of street, etc, 2 heavy coats asphaltum varnish; **under sides of bridges**, rest of columns, etc., 2 heavy coats standard white paint;* ballast side of trough floors, 1 part by weight refined Trinidad asphalt and 3 parts straight run coal tar pitch at 300° F, **Y.**

Wherever there is a tendency for water to collect, the spaces must be filled with a waterproof material, **C, Cc.**

First coat paint of graphite or carbon primer, **Oo.**

In highway bridges, upper surfaces of metal floor plates thoroughly coated with asphalt, **Oo.**

VI. ERECTION.

The Contractor is usually required

(1) to unload materials after delivery, to furnish falseworks and appliances, to remove the old bridge, to alter existing bridge seats;

(2) to drill and set anchor bolts, to erect and adjust the superstructure, and sometimes to furnish and place the wooden floor beams;

(3) to remove falseworks and appliances;

(4) to keep the road open for traffic and to avoid interference with any other thoroughfare by land or water and interference with other contractors; to furnish and pay watchmen; to keep material clean and in good order; and to assume all risks of damage to persons or property by reason of storms, floods or other casualties;

(5) to furnish pilot nuts for the protection of the ends of pins in driving.

---

(2) DIGEST OF SPECIFICATION FOR COMBINATION RAILROAD BRIDGES.†

By Baltimore and Ohio Railroad Co., 1901.

I. GENERAL DESIGN.

Type, Howe.

Rods of steel, with upset ends; standard nut and lock nut on each end.

Cast iron joint boxes and packing spools.

Steel gib plates from 1.25 ins thick for 1.25 inch rod, to 1.75 ins thick for 2.5 inch rod.

Splices in lower chord generally of steel construction.

II. MATERIAL.

Lumber, Georgia yellow pine, white oak or white pine.

Rolled steel. Open hearth. Ultimate strength 60,000 lbs per sq inch,

---

* Standard red lead paint. 5 gals contain 100 lbs pure red lead, 4 gals pure raw linseed oil, one-half pint Japan, free from benzine, **Y.**

Standard white paint. 5 gals contain 42 lbs pure white lead in oil, 21 lbs white zinc in oil, 3 gals pure raw linseed oil, **Y.**

At least 48 hours between coats, and between final shop coat and loading, **Y.**

† To be used only for temporary purposes.

permissible variation, 5 000 lbs; elastic limit, 30,000 lbs; elongation 25 per cent in 8 ins; to bend 180° flat upon itself.

III. LOADS.

Dead Load.

Timber taken at 4.5 lbs per foot board measure. Track 100 lbs per lin ft.

Live Load.

Max intended load + 25 per cent, to provide for increase and impact.

IV. STRESSES AND DIMENSIONS.

Limiting Unit Stresses.

Timber, lbs per sq inch, max	Yellow pine	White pine	White oak
Bending or direct tension	1,200	800	1,000
Columns under 17 diams in length	900	600	750
Columns over 17 diams in length	1,200–18 n	800–12 n	1,000–15 n
where n = length ÷ least thickness; n max = 40.			
Shearing, along grain	150	100	200
Bearing, in direction of grain	1,500	1,000	1,250
Bearing, perpendicular to grain	350	200	500

In columns made up of several sticks placed side by side, and bolted together at intervals, each stick treated as an independent column.

Steel rods, max unit stress = 12,000 lbs per sq inch.

Floor beams designed to carry the dead load and the heaviest engines in service without impact allowance. Reinforce for future increase of loads.

For loadings in excess of that used in designing, reduce speed from 60 to 15 miles per hour, as loads increase to limit of 25 per cent increase of load.

V. PROTECTION.

Steel rods, gibs, etc , 1 coat of paint in shop; 2 after erection.

Wood, at joints and at points of contact, to be painted.

Bolt and rod holes to be saturated with paint.

---

(3) DIGEST OF SPECIFICATION FOR ROOF TRUSSES, STEEL FRAMEWORK AND BUILDINGS.

By Baltimore and Ohio Railroad Co., 1901.

I. GENERAL DESIGN.

Made principally of shapes. No adjustable members, except in lateral bracing. Lateral bracing proportioned for a full wind pressure of 30 lbs per sq ft of exposed surface, acting in any direction. Tension members in bracing must in all cases pull directly against a stiff strut. If building is enclosed and the work is exposed to the action of gases, no open spaces less than 1 inch wide left between members, or open pockets inaccessible for painting.

II. MATERIAL.

Min thickness, 0 25 inch. When subject to the action of gases, five-sixteenths inch if building is open; 0.375 inch if enclosed.

III. LOADS.

Snow, 20 lbs per sq ft of horizontal projection of roof surface. Wind, 30 lbs per sq ft, horizontal, in any direction. Min total, 40 lbs per sq ft.

Covering. For roofs, and for sides unless otherwise ordered, corrugated sheets, No. 22 gage, 26 ins wide; corrugations, 2.5 ins; 3 ins for slope of 1 on 2; 6 ins for less slope. Purlins not more than 4 ft apart between centers.

IV. STRESSES.

Columns sustaining roof are considered as hinged at base, unless so anchored as to be absolutely fixed.

Unit stresses, if subject to no moving load other than wind, see **B**, in Digest of Specifications for Steel Bridges, and Digest (2) of B & O R R Specification for Combination Bridges. Stresses given in the latter to be increased 25 per cent.

V. PROTECTION.

Three coats of paint. If exposed to gases, use bridge paint (see **B** in Steel Bridge Specifications); if not, use standard building paints.

SUSPENSION BRIDGES.

Art. 1. Table of data required for calculating the main chains or cables of suspension bridges. Original.

Deflection in parts of the Chord.	Deflection in Decimals of the Chord.	Length of Main Chains between Suspension Piers, in parts of the Chord.	Tension on all the Main Chains at either Suspension Pier, in parts of the entire Suspended Wt. of the Bridge, and its Load.	Tension at the Center of all the Main Chains; in parts of the entire Suspended Wt of the Bridge, and its Load.	Angle of Direction of the Chains at the Piers. Deg	Min.	Natural Sine of the Angle of Direction of the Chains, at the Piers.	Natural Cosine of the Angle of Direction of the Chains at the Piers.
1-40	.025	1.002	5.03	5.00	5	43	.0995	.9950
1-35	.0286	1.002	4.40	4.37	6	31	.1135	.9935

9-20	.45	1.403	.572	.278	60	57	.8742	.4855
½	.5	1.480	.559	.250	63	26	.8944	.4472

These calculations are based on the assumption that the curve formed by the main chains is a parabola; which is not strictly correct. In a finished bridge, the curve is between a parabola and a catenary; and is not susceptible of a rigorous determination. **It may save some trouble in making the drawings** of a suspension bridge, to remember that when the deflection does not exceed about $\frac{1}{10}$ of the span, a segment of a circle may be used instead of the true curve, inasmuch as the two then coincide very closely; and the more so as the deflection becomes less than $\frac{1}{10}$. The dimensions taken from the drawing of a segment will answer all the purposes of estimating the quantities of materials.

The deflection usually adopted by engineers for great spans is about $\frac{1}{12}$ to $\frac{1}{15}$ the span. As much as $\frac{1}{10}$ is generally confined to small spans. The bridge will be stronger, or will require less area of cable, if the deflection is greater, but it then undulates more readily, and as undulations tend to destroy the bridge by loosening the joints, and by increasing the momentum, they must be specially guarded against as much as possible. The usual mode of doing this is by trussing the hand-railing; which with this view may be made higher, and of stouter timbers than would otherwise be necessary. In large spans, indeed, it may be supplanted by regular bridge-trusses, sufficiently high to be braced together overhead as in the Niagara Railroad bridge, where the trusses are 18 ft high; supporting a single-track railroad on top, and a common roadway of 19 ft clear width, below.*

* The writer believes himself to have been the first person to suggest the addition of very deep trusses braced together transversely, for large suspension bridges. Early in 1851 he designed such a bridge, with four spans of 1000 ft each, and two of 500; with wire cables; and trusses 20 ft high. It was intended for crossing the Delaware at Market Street, Philada. It was publicly exhibited for several months at the Franklin Institute, and at the Merchants' Exchange; and was finally stolen from the hall of the latter. Mr. Roebling's Niagara bridge, of 800 ft span, with trusses 18 ft high, was not commenced until the latter part of 1852; or about 18 months after mine had been publicly exhibited.

Another very important aid is found in deep longitudinal floor timbers, firmly united where their ends meet each other. These assist by distributing among several suspender rods, and by that means along a considerable length of main cable, the weight of heavy passing loads; and thus prevent the undue undulation that would take place if the load were concentrated upon only two opposite suspenders. With this view, the wooden stringers under the rails on the Niagara bridge are made virtually 4 ft deep. The same principle is evidently good for ordinary trussed bridges.

Another mode of relieving the main cables is by means of *cable-stays:* which are bars of iron, or wire ropes, extending like *c y*, Fig 1, from the saddles at the points of suspension *c*, *d*, obliquely down to the floor, or to some part of the truss. In the Niagara bridge are 64 such stays, of wire ropes of 1⅝ inch diam; the longest of which reach more than quarter way across the span from each tower. They transfer much of the strain of the wt of the bridge and its load directly to the saddles at the top of the towers, thereby relieving every part of the main cable, and diminishing undulation. They end at *c* and *d*, where they are attached, not to the cables, but to the saddles. They of course do not relieve the *back stays*.

The greatest danger arises from the action of strong winds striking below the floor, and either lifting the whole platform, and letting it fall suddenly; or imparting to it violent wavelike undulations. The bridge of 1010 ft span across the Ohio at Wheeling, by Charles Ellet, Jr, was destroyed in this manner. It is said to have undulated 20 ft vertically before giving way. It had no effective guards against undulation; for although its hand-railing was trussed, it was too low and slight to be of much service in so great a span Many other bridges have been either destroyed or injured in the same way. When the height of the roadway above the water admits of it, the precaution may be adopted of tie-rods, or anchor rods, under the floor at different points along the span, and carried from thence, inclining downward, to the abutments, to which they should be very strongly confined. In the Niagara Railroad bridge 56 such ties, made of wire ropes 1¼ inch diam, extend diagonally from the bottom of the bridge, to the rocks below. They, however, detract greatly from the dignity of a structure

Mr Brunel, in some cases, for checking undulations from violent winds striking *beneath* the platform, used also *inverted* or *up-curving* cables under the floor Their ends were strongly confined to the abuts several ft below the platform; and the cables were connected at intervals, with the platform, so as to hold it down.

Art. 2. The angle *a d g*, or *a c i*, Fig 1, which a tang *d g* or *c i* to the curve at either point of suspension *c* or *d*, forms with the *hor* line *c d* or chord, is called **the angle of direction of the main chains,** or cables, at those points. Frequently the ends *e h*, and *d r*, of the chains, called the **backstays,** are carried away from the suspension piers in straight lines; in which case the angles *l d r*, *e c h*, formed between the hor line *e l* and the chain itself, become the angles of direction of the backstays.

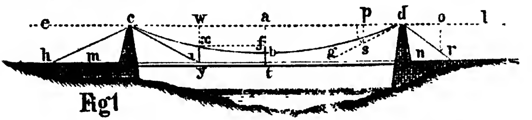

Fig 1

$$\textbf{Sine of angle of direction } a\,d\,g = \frac{\text{Twice the deflection } a\,b}{\sqrt{(\text{twice the deflection})^2 + (\text{Half the chord})^2}}$$

NOTE 1. The direction of the tang *d g* or *c i*, can be laid down on a drawing, thus: Continue the line *a b*, making it twice as long as *a b*; then lines drawn from *d* and *c* to its lower end, will be tangs to the parabolic curve at the points of suspension.

NOTE 2. **If the chord *c d* be not hor,** as sometimes is the case, the angle must be measured from a hor line drawn for the purpose at each point of suspension, as the two angles will in that case be unequal, the piers being of unequal heights.

Tension on all the main chains or cables, together, at either one of the piers, *c* or *d*, Fig 1.

$$= \frac{\text{Half the entire suspended weight of the clear span and its load}}{\text{Sine of angle of direction } a\,d\,g}$$

$$\textbf{or} = \frac{\sqrt{(\tfrac{1}{2}\text{ Span})^2 + (2\text{ Defl})^2}}{2\text{ Deflection}} \times \begin{array}{c}\text{Half the entire sus-}\\\text{pended weight of}\\\text{the clear span and}\\\text{its load.}\end{array}$$

Tension on all the main chains or cables, together, at the middle, *b*, of the span, Fig 1.

$$= \frac{\text{Half the entire suspended weight of the clear span and its load} \times \text{Cosine of angle of direction } a\,d\,g}{\text{Sine of angle of direction } a\,d\,g}$$

$$\textbf{or} = \frac{\text{Half the entire suspended weight of the clear span and its load} \times \text{Half the span}}{\text{Twice the deflection}}$$

The diff between the tensions at the middle, and at the points of suspension, is so trifling with the proportion of chord and deflection commonly adopted in practice, viz, from about $\frac{1}{10}$ to $\frac{1}{15}$, that it is usually neglected; inasmuch as the saving in the weight of metal would be fully compensated for by the increased labor of manufacture in gradually reducing the dimensions of the chains from the points of suspension toward the middle, and in preparing fittings for parts of many different sizes. The reduction has, however, been made in some large bridges with wrought-iron main chains; but in none with wire cables.

Art. 2A. As it is sometimes convenient to form a rough idea at the moment, of the size of cables required for a bridge, we suggest the following rule for finding approximately the area in sq ins of *solid* iron in the wire required to sustain, with a safety of 3,* the weight of the bridge itself, together with an extraneous load of 1.205 tons per foot run of span; which corresponds to 100 lbs per sq ft of platform of 27 ft *clear available* width. This suffices for a double carriage-way, and two footways. The deflection is assumed at $\frac{1}{12}$ of the span; and the wire to have an ultimate strength of 36 tons per solid square inch,

For spans of 100 ft or more,

RULE. Mult the span in feet by the square root of the span. Divide the prod by 100. To the quot add the sq rt of the span. Or, as a formula,

$$\textit{Area of SOLID metal of all the cables; in square ins; for spans over 100 feet} = \frac{\textit{span} \times \textit{sq rt of span}}{100} + \textit{sq rt of span.}$$

For spans less than 100 feet, proportion the area to that at 100 ft.

If a defl of $\frac{1}{10}$ is adopted instead of $\frac{1}{12}$, the area of the cables may be reduced very nearly $\frac{1}{7}$ part.

The following table is drawn up from this rule. The 3d col gives the united areas of all the actual wire cables, when made up, including voids. (Original.)

Span in Feet.	Solid Iron in all the Cables.	Areas of all the Finished Cables.	Span in Feet.	Solid Iron in all the Cables.	Areas of all the Finished Cables.	Span in Feet.	Solid Iron in all the Cables.	Areas of all the Finished Cables.
	Sq Ins.	Sq. Ins.		Sq. Ins.	Sq. Ins		Sq Ins.	Sq. Ins.
1000	348	446	400	100	128	150	30.6	39.2
900	300	385	350	84	108	125	25.2	32.3
800	254	326	300	69	89	100	20	25.6
700	212	272	250	55	71	75	15	19.2
600	171	219	200	42	54	50	10	12.8
500	134	172	175	36.4	46.7	25	5	6.4

Having the areas of all the actual cables, we can readily find their diam. Thus, suppose with a span of 500 ft, we intend to use four cables. Then the area of each of them will be $\frac{172}{4} = 43$ sq ins, and from the table of circles, we see that the corresponding diam is full 7⅜ ins.

The above areas are supposed to allow for the increased wt of a depth of truss, and other additions necessary to secure the bridge from violent winds, and from undue vibrations from passing loads.

Weight, sufficiently provided for, is of great service in reducing undulation.

We do not think that diagonal horizontal bracing should, as is usual, be omitted under the floor. It may readily be effected by iron rods.

All the cables need not be at the *sides* of the bridge. One or more of them may be over its axis; especially in a wide bridge. One wide footpath in the center may be used, instead of two narrow ones at the sides.

The platform or roadway should be slightly cambered, or curved upward, to the extent say of about $\frac{1}{100}$ of the span.

* The writer must not be understood to advocate a safety of 3 against 100 lbs per sq ft, in addition to the weight of the bridge, in all cases. He believes that limit to be about a sufficient one for a properly designed wire suspension bridge for ordinary travel; but for an important railroad bridge, he would (according to position, exposure, &c) adopt a safety of at least from 4 to 6 against the greatest possible load, added to the wt of the bridge. A train of cars opposes a great surface to the action of side winds; and trains must run during violent storms, as well as during calms; but a large open bridge for common travel is not likely to be densely crowded with people during a severe storm.

Art. 3. Tension on the back-stays, $c\,h$ and $d\,r$, Fig 1. and strains on the piers, or towers, or pillars. If the angle of direction $a\,d\,g$ and the angle $l\,d\,r$, between the back-stays and the horizontal, are equal to each other, the tension on the back-stays will be equal to that on the main cables at the tops of the piers; and the pressure on the piers will be vertical, but if the two angles are unequal, then these tensions and pressures will depend, to a very important extent, upon the manner in which the chains or cables are fixed to, or laid upon, the tops of the piers.

Art. 4. In Figs 2, 3 and 4, the piers $d\,n\,m$ are supposed to be immovable, and the cables $k\,d\,u$, passing over them, rest immediately upon horizontal rollers *which have no other motion than that of revolving about their horizontal axes; the frame to which they are attached being bolted to the top of the pier.* On these rollers the cables slide, when changes of loading or of temperature produce changes in their directions.

In this case the **tension on the back-stays** is equal to that on the main cable See Funicular Machine.

To find the direction and amount of the **pressure on the pier:** from d, Fig 2, 3 or 4, lay off $d\,s$ and $d\,r$, each equal, by scale, to the tension, in tons, on the main chain at d, and from s and r lay it off to v In other words, draw the parallelogram $d\,s\,v\,r$, and its diagonal $d\,v$ Then will $d\,v$ give the *direction* and *amount* of the pressure upon the pier.

When, as in Fig 2, the angles $a\,d\,g$ and $l\,d\,u$ are *equal*, the pressure $d\,v$ will be vertical and equal to the *entire* weight of the clear span and its load.

When, as in Figs 3 and 4, the angles $a\,d\,g$ and $l\,d\,u$ are *unequal*, the pressure $d\,v$ will not be vertical but will incline from d toward the smaller angle.

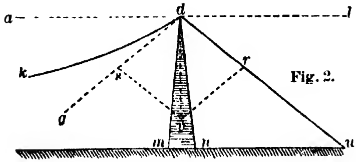

Fig. 2.

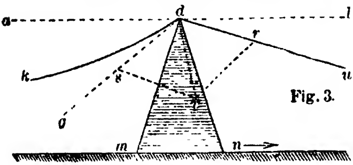

Fig. 3.

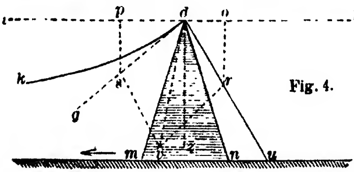

Fig. 4.

When, as in Fig 3, $a\,d\,g$ exceeds $l\,d\,u$, the pressure $d\,v$ will be *less* than the entire weight of the clear span and its load.

When, as in Fig 4, $l\,d\,u$ exceeds $a\,d\,g$, the pressure $d\,v$ will be *greater* than the entire weight of the clear span and its load.

If we suppose symmetrical piers, $d\,n\,m$, to be used in each case, the base $m\,n$ of that in Fig 2, may be much narrower than in the other two figs; because, the direction of $d\,v$ being vertical the pressure has no tendency to overturn the pier. In Fig 2, the masonry of the pier should be laid in the usual horizontal courses, in order that its bed joints may be at right angles to the pressure upon them.

But, in Figs 3 and 4, if the bases were made as narrow as in Fig 2, the lines of direction $d\,v$, of the pressure, would fall outside of them; and the piers would consequently be in danger of overturning. Also, the stones of the masonry, if laid in horizontal courses, would have a tendency to slide on each other. To prevent this, the beds should be at right angles to $d\,v$

In Fig 3 the obliquity of the pressure would tend to slide the base of the pier *outward* as shown by the arrow; but in Fig 4, *inward* This tendency is produced by the *horizontal* component of the force $d\,v$. The amount of this may be found thus, in either fig: From d downward draw a vert line as in Fig 4, and from v a hor one meeting it in z, then $v\,z$, measured by the same scale of tons as before, will give this horizontal force, and $d\,z$ will give the vertical component of the pressure $d\,v$. The effect upon the pier, of the one pressure $d\,v$ is precisely the same as would be produced upon it by one vertical force equal to $d\,z$ and a horizontal one equal to $v\,z$ acting at the same time, as explained under Composition and Resolution of Forces.

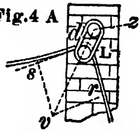
If, in either fig, we draw the vert lines $s\,p$ and $r\,o$, see Fig 4, then $d\,o$, meas'd by the foregoing scale, will give the tons of horizontal pull, and $r\,o$ the vertical pressure, produced on the pier by the back-stay; and $p\,d$ and $p\,s$ will, in like manner, give the corresponding forces produced by the main chain. If we add together $r\,o$ and $p\,s$ they will be found to be equal to $d\,z$, and if we subtract $d\,o$ from $p\,d$, their difference will equal $v\,z$. It is this difference only that tends to slide, or to upset, the pier; the other portions of $d\,o$ and $p\,d$ neutralizing each other in that respect.

The foregoing strains may all be *calculated*, thus:

Horizontal pull inward by the main chain = Tension × Cosine of $a\,d\,g$
" " **outward by the back-stay** = Tension × Cosine of $l\,d\,u$.
Vertical pressure by main chain = Tension × Sine of $a\,d\,g$.
" " " **back-stay** = Tension × Sine of $l\,d\,u$.

Art. 5. If the cables pass freely over a loose pin, d, Fig 4 A, supported by a link L, hanging from the fixed pin z, and capable of moving freely about both of its pins, the tension in the back-stay will, as before, be equal to that in the main cable; and the direction and amount of the strain on the piers will be found in the same way as for Figs 2, 3 and 4; namely: lay off $d\,s$ and $d\,r$, each equal to the tension, and draw the parallelogram $d\,s\,v\,r$. Then will $d\,v$ give the amount and direction of the strain on the piers. This last will, of course, be transmitted through the pins and the link. The amount of tension on the link will be given by the length of $d\,v$; and the link (being free to move) will be in line with this tension. The shearing strain on each pin is also given by $d\,v$.

Fig.4 A



Art. 6. But if the ends of the cable and back-stay, Figs 4 B, 4 C and 4 D, at the top of the pier, be *made fast* to a truck or wagon which is supported by rollers on a smooth platform on top of the pier, the axles of the rollers being fixed in the truck, then the strain on the back-stay will not be the same as that on the cable, unless the angles $a\,d\,g$ and $l\,d\,u$ are equal, as in Fig 4 B.

If $a\,d\,g$ exceeds $l\,d'\,u$, as in Fig 4 C, the strain on the back stay will be less than that on the cable, and vice versa (Fig 4 D).

But, in either case, if the top of the pier is horizontal, as is usually the case, the horizontal components of the strains on the cables and on the back-stays, will be equal, and will thus counteract each other, and there will consequently be no horizontal or oblique strain on the pier. That is, the strain on the pier will be vertical.

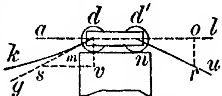


Fig.4 B

To find the amount of the tension on the back-stay, and of the pressure on the pier: on $d\,g$ in either Fig 4 B, 4 C or 4 D, lay off $d\,s$, equal, by scale, to the tension on the cable at d. Draw $d\,v$ perpendicular to the surface $m\,n$ on which the rollers rest. We assume that $m\,n$ is horizontal, as is generally, *but not necessarily*, the case and $d\,v$, therefore, vertical. Draw $s\,v$ horizontal, or parallel to $m\,n$.*

Then $s\,v$ will give the horizontal pull of the main cable on the wagon, and $d\,v$ will give the vertical pressure of the wheel d on the tower (to which that of the wheel d' has yet to be added). From d' lay off $d'\,o$ horizontal, and equal to $s\,v$ and draw $r\,o$ vertically. Then $d'\,r$ will give the amount of the pull on the back stay, and $r\,o$ will give the vertical pressure of the wheel d' on the pier; which must be added to $d\,v$ for the *total* vertical pressure.

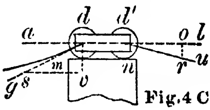

Fig.4 C

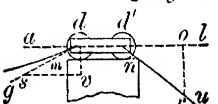

Fig.4 D

Or the various strains may be *calculated*, thus:

Horizontal pull $s\,v$ or $d'\,o$ at the top of the pier } = Horizontal pull at middle of span = Tension $d\,s$ in cable at d × Cosine of $a\,d\,g$.

Strain $d'\,r$ in back-stay } = Horizontal pull $s\,v$ or $d'o$ at top of pier, or at middle of span ÷ Cosine of $l\,d'\,u$.

Pres on pier, perp to surf on which the rollers rest } $= d\,v + r\,o = \left(\text{Tension } d\,s \text{ on main cable at } d \times \text{Sine of } a\,d\,g\right) + \left(\text{Tension } d'\,r \text{ on back stay} \times \text{Sine of } l\,d'\,u\right)$

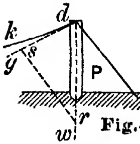

Fig.4 E

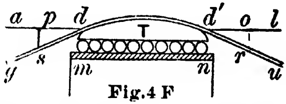

Fig.4 F

Art. 7. When, as is sometimes the case in light bridges, the piers are posts, P Fig 4 E, of wood or iron, hinged at the bottom, and having the cables and back-stays firmly fixed to their tops; from d draw $d\,s$, equal, by scale, to the tension on the main cable at d; and $d\,w$ toward the foot of the post. From s draw $s\,r$ parallel to the back stay, and meeting $d\,w$ in r. Then will $s\,r$ give the strain in the back stay, and $d\,r$ will give the amount and direction of the pressure upon the post.

Art. 8. As in the Niagara bridge, the cables often merely rest upon movable trucks, or saddles, T Fig 4 F, curved on top to avoid sudden bends in the cables and resting upon loose rollers which lie upon a thick horizontal iron plate bolted to the top of the pier, and are free to move horizontally. In such cases the angles $a\,d\,g$ and $l\,d'\,u$ are made equal; so that the pulls

* The lines $a\,l$ and $s\,v$ must be drawn *parallel to the surface* m n *on which the wagon rests*, whether said surface be horizontal or inclined.

, s and d' r are equal, as are also their horizontal components p d and d' o ; and the pressures on the pier are vertical; and if changes of temperature or of loading produce slight changes in the angles a d g and i d' u, the truck will (by reason of the inequality thus brought about between the hori zontal components) move far enough to restore the equality between the angles, and between the horizontal components, and consequently the pressure upon the pier will at all times be vertical.

Art. 9. To find, approximately, the length of a main chain c b d; Fig. 1; having the span c d, and the middle defl a b. See preceding table, Art 1.

Half length of main chain $= \sqrt{1\frac{1}{3}\ (\text{defl}^2) + (\frac{1}{2}\ \text{chord})^2}$.

In Menai bridge the chord c d is 579.874 ft. and the defl is 43 ft.

According to the above formula, the entire length is 588.3 feet. By actual measurement the chain is precisely 590 feet. The approximate rule below gives 589 764 ft.

NOTE. The lengths obtained by this rule are only approximate, because the calculation is based upon the supposition that the chains form a parabolic curve; whereas, in fact, the curve of a finished bridge is neither precisely a parabola, nor a catenary, but intermediate of the two.

The following simple rule by the writer is quite as approximate as the foregoing tedious one when, as is generally the case, the defl is not greater than $\frac{1}{12}$ of the chord, or span.

Length of main chain when defl does not exceed one-twelfth of the span = chord + .23 defl.

Art. 10. To find, approximately, the length of the vert suspending rods x y, &c, Fig 1; assuming the curve to be a parabola.

Let x, Fig 1, be any point whatever in the curve; and let x w be drawn perp to the chord c d; and x f perp to a b; then in any parabola, as $a\ c^2 : a\ n^2 :: a\ b : b\ f$. And b f thus found, added to b t, (which is supposed to be already known, being the length decided on for the middle suspending rod,) gives x y, the length of rod reqd at the point x, and so at any other point.

If b f thus found be taken from the middle deflection a b, it leaves w x; and thus any deflection w x of the main chain or cable, may be found when we know its hor dist, a w, from the center, a, of the span.

In the foregoing rule, the floor of the bridge is supposed to be straight; but generally it is raised toward the center; and in that case, the rods must first be calculated as if the floor were straight and the requisite deductions be made afterward. When it rises in two straight lines meeting in the center, the method of doing this is obvious. When an arc of a circle is used, its ordinates may be calculated and deducted from the lengths obtained by this rule. Or, having drawn the curve by the rule for drawing a parabola, the dimensions can be approximated to by a scale. The adjustments to the *precise* lengths must be made during the actual construction of the bridge, by means of nuts on their lower screw-ends. The rods require, therefore, only to be made *long enough* at first.

The towers, piers, or pillars, which uphold the chains or cables, admit of an endless variety in design. According to circumstances, they may consist each of a single vertical piece of timber, or a pillar of cast or wrought iron; or of two or more such, placed obliquely, either with or without connecting pieces; like the bents of a trestle, Or they may be made (with any degree of ornamentation) of cast iron plates, as in iron house-fronts. Or they may be of masonry, brick, or concrete; or of any of these combined.

Each of the suspending-rods, through which the floor of the bridge is upheld by the main chains, requires merely strength sufficient to support safely the greatest load that can come upon the interval between it and half-way to the nearest rod on each side of it; including the wt of the platform, &c, along the same interval.

In anchoring the backstays into the ground, it is necessary to secure for them a sufficiently safe resistance against a pull equal to the strain, upon the backstay.

As to the anchorage of the cables below the surface of the ground, natural rock of firm character is the most favorable material that can present itself. When it is not present, serious expense in masonry must be incurred in large spans, in order to secure the necessary weight to resist the pull of the cables. Our Figs 4½ give ideas of the modes most frequently adopted. For a very small bridge, such as a short foot bridge, for instance, the backstays may simply be anchored to large stones, t, Fig A, buried to a sufficient depth. Or, if the pull is too great for so simple a precaution, the block of masonry, m m, may be added, enclosing the backstay. A close covering of the mortar or cement of the masonry has a protecting effect upon the iron.

To avoid the necessity for extending the backstays to so great a dist under ground, they are usually curved near where they descend below the surface, as shown at B, D, and E; so as sooner to reach the reqd depth. This curving, however, gives rise to a new strain, in the direction shown by the arrows in Figs B and D. The nature of this strain, and the mode of finding its amount, (knowing the pull on the backstay,) are very simple; and fully explained under the head of Funicular Machine. The masonry must be disposed with reference to resisting this strain, as well as that of the direct pull of the backstay. With this view, the blocks of stone on which the bend rests should be laid in the position shown in Fig D; or by the single block in Fig B. Sometimes the bend is made over a cast-iron chair or standard, as at x, Fig F, firmly bolted to the masonry.

Fig E shows the arrangement at the Niagara railway bridge of 821⅓ ft span. The wire backstays end at c c; and from there down to their anchors, they consist of heavy chains; each link of which is composed of (alternately) 7 or 8 parallel bars of flat iron, with eye ends, through which pass bolts Each of the 7 bars of each link is 1.4 ins thick, by 7 ins wide, near the

lowest part of the chain; but they gradually increase from thence upward, until at c, c, where they unite with the wire cable, the sectional area of each *link* is 93 sq ins. These chain backstays pass in a curve through the massive approach walls. (28 ft high,) and descend vertically down shafts s, s, 25 ft deep in the solid rock. Here they pass through the cast-iron anchor-plates, to which they are confined below by a bolt 3½ ins diam. The anchor plates are 6½ feet square, and 2½ ins thick; except for a space of about 20 ins by 26 ins, at the center where the chains pass through, where they are 1

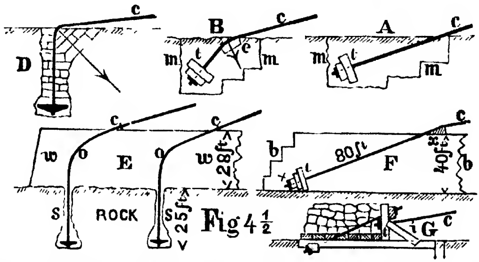

Fig 4½

foot thick. Through this thick part is a separate opening for each bar composing the lowest link. From this part also radiate to the outer edges of the lower face of the plate, eight ribs, 2½ ins thick. The shafts s, s, have rough sides, as they were blasted; and average 3 ft by 7 ft across; except at the bottom, where they are 8 ft square. They are completely filled with cement masonry, with dressed beds, well in contact with the sides of the shafts; and thoroughly grouted, thus tightly enveloping the chains at every point, as does also the masonry of the approach wall *w w*; which extends 28 ft above ground, and is 6 ft thick at top, and 10½ ft thick at its base on the natural rock.

D, Figs 4½, shows a mode that may be used in most cases, for bridges of any span. The depth and the area of transverse section of the shaft, and consequently the quantity of masonry in it, will depend chiefly upon whether it is sunk through rock, or through earth. If through firm rock, then if its sides be made irregular, and the masonry made to fit securely into the irregularities, much reliance may be placed upon it to assist the weight of the masonry in resisting the pull on the backstays. Earth also assists materially in this respect.

F is the arrangement in the Chelsea bridge of 333 feet span, across the Thames, at London; Thos. Page, eng. The space from one wall *b b*, to the opposite one, is 45 feet; and is built up solid with brickwork and concrete; except a passage-way 4 ft wide, and 5 ft high, along the backstay; and a small chamber behind the anchor-plates. It rests chiefly on piles.

The arrangement by Mr Brunel, in the Charing Cross bridge, London,* is very similar. In it also the entire abutment rests on piles; and is 40 ft high, 30 ft thick, and solid, except a narrow passage-way along the chains. The backstays extend into it 60 ft. Span 676 feet. Defl 50 feet.

G is intended merely as a general hint, which, variously modified, may find its application in the case of a small temporary, or even permanent bridge; for the number of pieces, *t*, *t*, &c, may be increased to any necessary extent; and they may be made of iron or stone, instead of wood.

In order that the backstays may be accessible, they are frequently carried through openings left in the masonry for the purpose. Thus, the masses, *m m*, of masonry, at A and B, Figs 4½, instead of being made solid, may consist of two parallel walls, between which the backstay may pass; and the anchor-stones, or anchor-plates, will extend across the space between the walls, and have their bearings against the ends of the walls. In D, E, and F, the cable may be supposed either to be tightly surrounded by the masonry and grouted to it, or else to be surrounded by a cylindrical passage-way like a culvert, so as to be at all times accessible.

Soft friable stone must be carefully excluded from such parts of the anchorage as are most directly opposed to the pull of the backstays.

If blocks of stone large enough for securing good bond are not procurable, heavy T-rails, bars of iron, or I-beams, may be advantageously introduced for that purpose.

The masses must be founded at such a depth as not to slide by the yielding of the earth in front of them.

For safety, it is well to disregard the effect of friction in diminishing the tension on the backstay, and to regard that tension as continuing uniform throughout the backstay to its end, even when the backstay is curved and imbedded in the masonry, as at E, Figs 4½.

The side parapets should be high and stout, so as to act as stiffening trusses, and should not be restricted to service as mere hand-rails or guards. As a rule of thumb their depth may be made $= \frac{1}{2}\sqrt{\text{span}}$, provided the depth be not less than that required for a hand-rail. The parapets should be stoutly constructed, with special attention to the strength of their joints, for these are exposed, by the undulations and lateral motions of the bridge, to violent deranging forces in all directions.

* Removed to Clifton, England, in 1863, and replaced by an iron truss railway and foot bridge.

RIVETS AND RIVETING.

The **weights** in the **following table** of course include the head: but the **lengths,** as usual, are taken "under the head," or are those of the shanks only. In practice, discrepancies of 5 or 6 per ct in wt may be expected.

Length of Shank. Ins.	Diameters of Rivets in inches.

The diam of rivets for bridge work is from ½ to 1 inch; usually ⅝ to ¾; and for plates more than .5 inch thick, it is about 1.5 times the thickness; and for thinner ones about twice; but these proportions are not closely adhered to. **The common form of rivets** as sold is shown at R, Figs 3, a **head** and the **shank** in one piece; and S shows the same when after being heated white hot it is inserted into its hole, and a second head (conical) formed on it by rapid hand-riveting as it cools. **When longer than about 6 ins** they are cooled near the middle before being inserted, lest their contraction in cooling should split off their heads. The hemispherical heads often seen, called **snap heads,** are formed by a machine. **The two heads alone require** about as much iron as 3 diams length of shank. **Length of a head** = about 1 diam of shank; and its **width** about 2 diams of shank.

Riveting of Steam and Water Tight Joints.

Joints for boilers and water-tight cisterns are usually proportioned about as per the following table by Fairbairn; and are made as shown either by Fig 1, or Fig 2. Fig 1 is called a **single-riveted,** and Fig 2 a **double-riveted lap-joint.** The dist *a a*, or *c c*, is the lap.

Mr Fairbairn considers the strength of the single-riveted lap-joint to be about .56; and that of the double-riveted, about .7 that of **one** of the full unholed

plates, when both joints are proportioned as in his following table. But some later experimenters consider about .5 and .6 as nearer the correct average. Experiments on the subject are quite conflicting; and it is plain that no one set of proportions can precisely suit all the different qualities of plate and rivet iron. With fair qualities of both there is every reason to rely upon .5 and .6 (or about one-seventh part less than Fairbairn's assumption) as safe for practice. These proportions include **friction** (Art 4), without which they would be *about* .4 and .5.

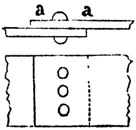

Fig 1.

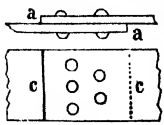

Fig 2.

Fairbairn's table for proportioning the riveting for steam and water-tight lap-joints.

Thickness of each plate	Diameter of rivets.	Length of shank before driving.	From center to center of rivets.	Lap in single riveting.	Lap in double riveting.

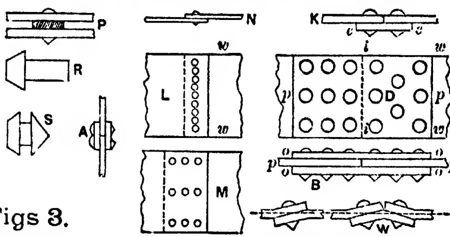
⅝	15-16	2¾	2½	2¾	4⅝
¾	1⅛	3¼	3	3¼	5½

Riveting of iron girders, bridges, &c.



Figs 3.

Art. 1. The subject of riveting is abstruse, and involved in much uncertainty; and experimental results are very discrepant. We here propose merely to confine ourselves to what is considered the best joint; and for safety we shall omit friction; see Art 4. In girder and bridge work the lap-joints above described are seldom used. Instead of them, the plates *p*, Figs 3, to be joined, are butted up square against each other, thus forming a **butt-joint,** *i i*, Fig D; and are united by either a single **covering-plate, cover, wrapper, fish-plate,** or **welt** *e e*, Fig K; or the best of all by two of them, as at A, or *o o*, *o o*, Fig B. In what follows, the term *plate* never includes the *covers.* The single cover, like the lap-joint, allows both plates and cover to bend under a strong pull, somewhat as at W, thus weakening them materially; whereas the double cover *o o*, *o o*, Fig B, keeps the pull directly along the axis of the plates, thus avoiding this bending tendency. It also brings the rivets into double shear, thus doubling their strength. When there is but one cover, it should be at least as thick as a plate; and when there are two, experience shows that each had better be about *two-thirds* as thick as a plate, although theory requires each to be but *half* as thick as a plate.

The length w w of covers across the joint is equal to that of the joint.

Butts require twice as many rivets as laps, because in the lap each rivet passes through both the joined plates; and in the butt through only one.

The rivets and plate on one side only (right or left) of the joint-line *i i* of any properly proportioned **butt-joint** D, represent the full strength of the joint, inasmuch as those on one side pull in one direction, against those on the other side, which pull in the opposite direction. Therefore in designing such joints we need keep in mind only those on one side, as is done in what follows. Thus a single, double, or triple-riveted **butt-joint** D implies one, two, or three rows of rivets **on each side** of the joint-line *i i*, and parallel to it. In a properly proportioned *lap* the strength is as **all** the rivets, because one-half of them do not pull against the other half, but one end of **every** rivet pulls in one direction, and its other end in the opposite direction.

The net iron, net plate, or net joint, is that which is left **between** the rivet holes, and **outside** of the two outer ones, all on a straight line drawn through the *centers* of the holes of *one* row. Its width and area are called the net ones of the joint. That between *other* rows does not increase the strength.

In Figs 3, N, and K, the rivets are in **single shear**, while those in A and B are in **double shear.**

Art. 2. Bridge-joints are not required to be steam or water-tight like those of boilers or cisterns; and, therefore, by increasing the breadth of the overlap, or the length of the covers, the rivets may be placed in several rows behind each other, as the 3 rows of 3 rivets each in M and D, instead of only one row of 9 rivets, as in L. By this means, without losing any of the strength of the 9 rivets, or of the **net** iron, we may narrow the width of the plate to an extent equal to the combined diams (6 in this case) of the holes thus dispensed with in the one row. Moreover, by using more than one row we lessen the weakening effect shown at W. This mode of placing the rivets directly behind each other in several rows, as at M, and at the left-hand half of Fig D, constitutes Mr Fairbairn's **chain riveting;** but the joint will be somewhat stronger if the rivets are placed in **zigzaging** order, as in the right-hand half of Fig D.

The dist apart of the rows from cen to cen should not be *less* than 2 diams. It is questionable to what extent this increase in the number of rows may be carried without an appreciable loss of strength in the rivets consequent upon the impossibility of quite equalizing the strains on the separate rows. But it is probable that if we do not exceed 2 or 3 rows in laps, or the same number *on each side* of the joint-line in butts, we may in practice assume that each row, and each rivet, is nearly equally strained.

Rivet-holes are usually of about one-sixteenth inch greater diam than the original rivet, so as to allow the hot rivet to be easily inserted The subsequent hammering swells the diam of the rivet until it fills the hole. We may either take this increased diam of rivet into consideration, as we have done, in calculating its shearing and crippling strength, as explained farther on, or with reference to increased safety we may omit it. **Drilled rivet-holes** are said to be better than punched ones, as the drilling does not injure the iron around them; but on the other hand their sharper edges are said to shear the rivets more readily. Hence, such edges are sometimes reamed off. Both these points are, however, disputed; and both modes are in common use.

The dist from the edge of a hole to the end of a plate or cover should not be *less* than about 1.2 diams, to prevent the rivets from tearing out the end of the plate; nor nearer the side edge of a plate than half the clear dist between two holes as given by the Rule in Art 5. The first is rather more than Fairbairn directs.

Rivet holes weaken the net iron left between them, not only by the loss of the part cut out, but either by disturbing the iron around them, or perhaps *by changing the shape of the net line of fracture, which may not then resist* tension as well as while it was a continuous straight line. Some deny both cause and effect entirely, each party basing its opinion on experiments. But the mass of evidence seems to the writer to show that the net iron loses on an average about one-seventh of the strength due to the net width With a view to safety, which we consider to be of paramount importance, we shall in what follows assume (until the question is definitely settled) that there **is** such a loss of strength in the net iron.

Riveted joints for resisting compression should depend, not as might be supposed upon their butting ends, but upon either the shearing or the crippling strength of the rivets; for contraction or bad work may throw the

pressure on the rivets. **Machine riveting** is somewhat stronger than that done (as is assumed in our examples) by hand. **The thickness of plates** used in girders, tubular bridges, &c, is usually .25 to .5 inch; with thicker ones up to 1 inch sparingly in large ones. **A packing piece,** as the shaded piece in P, is one inserted between two plates to prevent their being bent or drawn together by the rivets.

Art. 3. A riveted joint may yield in three ways after being properly proportioned, namely, by the shearing of its rivets; or by the pulling apart of the net plate between the rivet holes; or by the **crippling** (a kind of compression, mashing, or crumpling) of the plates by the rivets when the two are too forcibly pulled against each other. It also compresses the rivets themselves transversely, **at a less strain than the shearing one;** and this partial yielding of both plates and rivets allows the joint to **stretch,** and may thus produce injurious unlooked-for strains in other parts of a structure, considerably before there is any danger of actual fracture. Or in steam and water joints it may cause leaks, without farther inconvenience, or danger For a long time this crippling had entirely escaped notice, and it was supposed that the only important point in designing a riveted joint was that the tensile strength of the net plate, and the shearing strength of the rivets should be equal to each other.

The crippling strength of a joint is as the number of rivets, in a lap, or the number on one side of the joint-line in a butt × diam × thickness of joined plate. This product gives the crippled area of the joint. We shall here call the diam × thickness of plate, the **crippling area** of a rivet. If there are 2 or more plates (not covers) on top of each other at one joint, their united thickness is used for finding the crippling area. **The ultimate crippling unit,** by which the above product is to be multiplied for the actual ultimate crippling strength of the joint, may be safely taken at about 60000 lbs, or 26.8 tons, per sq inch.

The diam of a rivet in ins to resist safely a given single-shearing force is found thus: Mult the shearing force by the coef of safety, that is by the number, 3, 4, or 6, &c, denoting the required degree of safety. Call the product g. Mult the ultimate shearing strength per sq inch of the rivet-iron, by the decimal .7854. Call the product b. Divide g by b. Take the sq rt of the quotient. The shearing force and the shearing strength must *both* be in either lbs or tons.

Or by a formula,

$$\textbf{Diam in ins} = \sqrt{\frac{\text{Shearing force} \times \text{coef of safety}}{\text{Ult shearing strength per sq inch} \times .7854}}$$

If the rivet is to be double-sheared, first mult only half the shearing force by the coef of safety. Then proceed as before.

Or, near enough for practice, mult the diam in single shear by the decimal .7.

The ultimate shearing unit for average rivet-iron may be taken at about 45000 lbs, or 20.1 tons per sq inch of circular sheared section.

Table of ultimate single shearing strength of rivets.

(market sizes), in single shear; at 45000 lbs or 20.1 tons per sq inch.

This table is not to be used when as in our "Example," Art 5, the **crippling** strength of the rivet governs the strength of the joint.

If the rivet is in double shear it will have twice the strength in the table.

For the diam in double shear to equal the strength in the table, mult the diam in the table by the decimal .7; near enough for practice; strictly, .707.

Diam. Ins.	Diam. Ins.	lbs.	Tons.	Diam. Ins.	Diam. Ins.	lbs.	Tons.	Diam Ins.	Diam. Ins.	lbs.	Tons.
1/8	.125	552	.246		.562	11183	4.99	1	1.000	35343	15.8

3/8	.375	4970	2.22		.812	23[illegible]2	10.4	1 1/4	1.250	55224	24.6
	.437	6765	3.02	7/8	.875	27060	12.1		1.312	60885	27.2
1/2	.500	8836	3 94		.937	31064	13.9	1 3/8	1.375	66820	29.8

The tensile strength of a properly proportioned joint is equally as either the sectional area of the **net** plate (not covers) across the centers of only **one** row of rivets; or as the shearing or the crippling (as the case may be) areas of **all** the rivets in a lap, or of all the rivets **on one side** of the joint-line in a butt. The tensile strength of fair quality of plate iron, before the rivet holes are made, averages about 45000 lbs, or 20.1 tons per sq inch; but we shall for safety assume, as stated in Art 2, that the making of the holes reduces the strength of the **net** iron that is left about one-seventh part, or to 38500 lbs, or 17.2 tons per sq inch.

Rem. Even this is considerably too great for laps, or for butts with one cover, owing to the weakening of the iron in such by the bending shown at W, Figs 3. But we are not speaking of such.

Art. 4. The friction between the plates in a lap, or between the plates and the covers in a butt, produced by their being pressed tightly together by the contraction of the rivets in cooling, adds much to the strength of a joint while new, perhaps as much as 1.5 to 3 tons per sq inch of circ section of all the rivets in a lap or of all on one side of a single-cover butt; or 3 to 6 tons of all on one side of a double-cover butt. In quiet structures, this friction might continue to exist, either wholly or in part, for an indefinite period; but in bridges, &c, subject to incessant and violent jarring and tremor, it is probably soon diminished, or entirely dissipated. Hence good authorities recommend not to rely on it, and it is, therefore, omitted in what follows.

Art. 5. We now give rules for finding the number of rivets required for **a double cover butt-joint** (the only kind of which we shall treat), and their clear or net distance apart. This dist + one diam is the **pitch** of the rivets, or their dist from center to center. The principle of the rule will be explained further on, at Art 7.

First, select a diam of rivet either equal to or greater than .85 times the thickness of the plate. In practice they are generally 1.5 times for plates ½ inch or more thick; and 2 for thinner than ½ in.

Second, mult the greatest total pull in pounds that can come upon the entire joint by the coef (3, 4, or 6, &c) of safety, and call the product p.

Third, multiply the crippling area of the rivet (that is, its diam $\times$ the thickness of plate) by 60000. The prod is the ult crippling strength of a rivet. Call it m.

Fourth, divide p by m. The quotient will be the number of rivets to sustain the given pull with the reqd degree of safety.

Then, **the clear distance apart** will be

$$\frac{\text{Number of rows} \times \text{Diam} \times 60000}{38500}$$

Fifth. The clear dist from either end hole of a row to the side edge of the plate, should be not less than half the clear dist between two rivets in a row.

Example. A double-cover butt-joint in .5 inch thick plate is to bear an actual pull of 33750 lbs, with a safety of 4; or not to break with less than 33750 $\times$ 4 = 135000 lbs. How many rivets must it have; and how far apart must they be?

First, Here .85 times the thickness of the plate is .5 $\times$ .85 = .425 inch; therefore, our rivets must not be less than .425 inch in diam; but we will take .75 inch diam.

Second, The greatest pull $\times$ coef of safety = 33750 $\times$ 4 = 135000 lbs = p.

Third, The crippling area of a rivet $\times$ 60000 = .75 $\times$ .5 $\times$ 60000 = 22500 = m.

Fourth, $\frac{p}{m} = \frac{135000}{22500}$ = 6 rivets required on each side of the joint-line.

And the **clear space** or net width between them will be, **if the 6 rivets are in one row:**

$$\frac{\text{Diam} \times 60000}{38500} = \frac{45000}{38500} = 1.1688 \text{ ins}$$

And the **pitch** = net space + diam = 1.1688 + .75 = 1.9188 ins, = $\frac{1.9188}{.75}$ = 2.56 diams.

In practice, to avoid troublesome decimals, we might make the net space 1.2 ins; and the pitch 1.95; but to show farther on the working of the rule, we adhere to the more exact ones.

Fifth, The clear dist from each end hole to the side edge of the plate is half of 1.1688 = .5844 ins.

The entire width of net iron is equal to one clear space $\times$ number of rivets = 1.1688 $\times$ 6 = 7.0128 ins; and the entire width of plate is equal to one pitch $\times$ number of rivets = 1.9188 $\times$ 6 = 11.5128 ins

The area of cross section of unholed plate is 11.5128 × .5 = 5.7564 sq ins; its tensile strength **before the holes are made** is 5.7564 × 45000 = 259038 lbs

The strength of our joint, omitting friction, is therefore $\frac{135000}{259038}$ = .52 of that of the original unholed plate.

If the 6 rivets are in 2 rows of 3 rivets each, the **clear dist between two rivets** in one row will be twice as great as before, or twice 1.1688 = 2.3376 ins. **Pitch** = 2.3376 + .75 = 3.0876 ins = 3.0876 ÷ .75 = 4.12 diams. **Clear dist from** end hole to side edge of plate = half of 2.3376 = 1.1688. **Entire width of net iron** = 2.3376 × 3 = 7.0128 ins. **Entire width of plate** = 3.0876 × 3 = 9.2628 ins. **Area of cross section of unholed plate**=9.2628×.5=4.6314 sq ins. **Ultimate tensile strength, unholed** = 4.6314 × 45000 = 208413 lbs. **Ult strength of riveted joint,** omitting friction = $\frac{135000}{208413}$ = .65 of that of the unholed plate.

Thus we see that the arrangement with two rows gives the same strength as one row, with a less total width and area of plate. It of course requires *longer covers.*

If the 6 rivets are in 3 rows of 2 rivets each, the **area of cross section of the unholed plate** is 4.2565 sq ins. Its **tensile strength,** 191542 lbs. Strength of riveted joint = $\frac{135000}{191542}$ = 7 of that of the unholed plate.

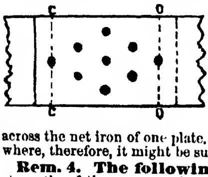
The entire width of net iron (7.0128 ins); its area (7.0128 × .5 = 3.5064 sq ins); and its ultimate tensile strength (3.5064 × 38500 = 135000 lbs), are the same in each case. The last is the required breaking strength of the joint, as in the beginning of our example; and is equal to the combined crippling strength of the six rivets.

Art. 6. The distance apart of the rows, from center to center of rivets, should not be less than two diameters of a rivet-hole.

Rem. 1. With our constants for tension, shearing, and compression, **the rivets will not yield first by shearing** in a double-cover butt (and of course in double shear), except when the diam is either equal to or **less** than .85 of the thickness of the plate, which will rarely happen. At .85 the crippling and shearing strength of a rivet are equal when using our assumed coeffs of crippling, shearing, and tension.

Rem. 2. Our example was chosen to illustrate the rule. It will rarely happen in practice that the rule will give a number of rivets without a fraction; or that may be divided by 2 and by 3 without a remainder. In case of a fraction, it is plainly best to call it a whole rivet; although the joint thereby becomes a trifle stronger than necessary. Or rivets of a slightly diff diam may be used. If the number of rivets comes out say 7 or 9, we may make 2 rows of 3 and 4, or of 4 and 5, &c. Moreover, the width of the plate is frequently fixed beforehand by some requirement of the structure, and we must arrange the rivets to suit, taking care in all cases to maintain the calculated area of net iron in one row, &c.

Rem. 3. We have (as we at first said we should do) confined ourselves to the simple butt-joint with 2 covers, and with the rivets in either 1, or in 2 or more parallel rows on each side of the joint-line; this being the strongest and the one in most common use in engineering structures. Necessity at times calls for less simple arrangements, for which we cannot afford space, and the strength of which is not so readily calculated. These sometimes yield results which appear strange to the uninitiated; thus, this lap-joint breaks across the net iron of one plate, along either c c or o o, *where there is most of it,* and where, therefore, it might be supposed to be the strongest.



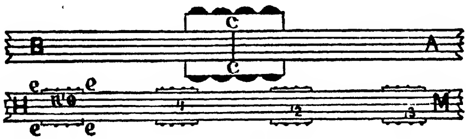
Rem. 4. The following table shows approximately the comparative strengths of the common forms of joints when properly proportioned; varying with quality of sheets, and of rivets:

	With friction.	Without friction.
The original unholed plate	1.00	1.00
Double-riveted butt with two covers	.80	.64
Double-riveted butt with one cover	.65	.52
Single-riveted butt with one cover	.50	.40
Double-riveted lap	.65	.52
Single-riveted lap	.50	.40

Rem. 5. The above tabular strengths for the **lap-joints** will be approximately attained by adopting the following proportions, according as the joint is double- or single-riveted.

	Double riv. zigzag.		**Single riv.**	
	In thicknesses.	In diams	In thicknesses	In diams.
Calling thickness of plate	1.	.6	1.	.6
Then make diam of rivet	1.67	1.0	1.67	1 0
" " breadth of lap	9 0	5.4	5 67	3.4
" " pitch from cen to cen	7.0	4.2	4 5	2.7
" " dist from *end* of plate to *edge* of holes	2.0	1.2	2.0	1.2
" " dist apart of rows from cen to cen	3.33	2.0		

Rem. 6. If two or more plates on top of each other, as the four in A B or M H, are to be jointed together so as to act as one plate of the thickness *c c*, the diams of the rivets, and the thickness of the covers *c c*, *e e* will depend upon whether the junctions of the plates are all in one line with each other as at *c c*, in A B, or whether they break joint with each other as at 0, 1, 2, 3 in M H.



It is plain that the two covers *c c* by means of their connecting rivets convey from A to B, across the joint *c c*, all the strength that partly compensates for the severance of the four plates at that joint; whereas the two covers *e e*, *e e*, and their rivets in like manner convey from *n* of one single plate, to *o* of the adjoining one, across the joint between those two letters, only the strength that partly compensates for the severance of that single plate; and so with the joints at 1, 2, and 3. Therefore the covers *c c*, and their rivets, must be four times as strong as those at any one of the four joints 0, 1, 2, 3. The first, *c c*, are to be regarded as joining two solid plates A and B, each of the fourfold thickness *c c*; and the others as joining two of the single thickness. The covers *c c* will, therefore, each be about two-thirds of the thickness *c c*; and the others each about two-thirds as thick as a single plate. Thus, suppose each of the 4 plates in A B or M H to be ¾ inch thick, making *c c* 3 ins. Then each cover, *c*, is ⅔ of 3 ins, or 2 ins thick; or the two covers, *c c*, together 4 ins, which is thus the effective thickness of the joint, *c c*. But each cover, *e e*, is only ⅔ of ¾ inch, or ½ inch thick; and the effective thickness of joint at either 0, 1, 2, or 3, is that of the 3 unbroken plates plus that of the 2 covers, or $(3 \times \frac{3}{4}) + (2 \times \frac{1}{2}) = 3\frac{1}{4}$ ins.

Art. 7. Principle of the Rule in Art 5. With our constants for shearing (45000 lbs per square inch) and for crippling (60000 lbs per square inch), and with diameter of rivet equal to, or greater than, .85 times the thickness of the plate, as by our rule, the *crippling* strength of a double cover butt joint will be equal to, or less than, its shearing strength. Therefore, to avoid waste of material, either in the plate or in the rivets, we must make

$$\text{Tensile strength of net plate across one row of rivets} = \text{Crippling strength of } all \text{ the rivets. Or.}$$

$$\text{Total net width of plate} \times \text{Thickness of plate} \times \text{Tension unit} = \text{Crippling area of one rivet} \times \text{Crippling unit} \times \text{Total number of rivets.}$$

Now, by Art 3, the crippling area of a rivet is = diam of rivet × thickness of plate. We take the crippling unit at 60000 lbs; and the tension unit at 38500 lbs. Therefore (transposing) we must make

$$\text{Total net width of plate} = \frac{\text{Diam of rivet} \times \text{Thickness of plate} \times 60000 \times \text{Total number of rivets}}{\text{Thickness of plate} \times 38500}$$

By making the clear distance between each end rivet of a row and the side edge of the plate = half the clear distance between two rivets in a row; and calling the sum of the two end distances one space, we have

$$\frac{\text{Number of } spaces}{\text{in a row}} = \frac{\text{Number of } rivets}{\text{in a row.}}$$

So that

The clear distance between two rivets in a row,

which is

$$= \frac{\text{Total net width of plate}}{\text{Number of } spaces \text{ in a row}}$$

is also

$$= \frac{\text{Total net width of plate}}{\text{Number of } rivets \text{ in a row}}$$

$$= \frac{\text{Diam. of rivet} \times \text{Thickness of plate} \times 60000 \times \text{Total number of rivets}}{\text{Thickness of plate} \times 38500 \times \text{Number of rivets in a row.}}$$

But

$$\frac{\text{Total number of rivets}}{\text{Number of rivets in a row}} = \text{Number of rows.}$$

Therefore, omitting "thickness of plate," common to both numerator and denominator, we have, as in rule in Art 5,

$$\textbf{Clear distance apart} = \frac{\text{Diam of rivet} \times 60000 \times \text{Number of rows}}{38500}$$

But if the diameter of the rivets is less than 0.85 times the thickness of the plates, the *shearing* strength of a double-cover butt join (with our assumed constants for shearing and crippling) is less than its crippling strength. In such cases, for the clear distance between two rivets in a row, say

$$\textbf{Clear distance} = \frac{\text{Circular area of a rivet} \times \text{Shearing unit}}{\text{Thickness of plate} \times \text{Tension unit}} \times 2$$

Rem. 1. Butt joints in double shear, or with 2 covers, being th only ones here considered, and inasmuch as rivets may always be used with a dian greater than .85 of the thickness of the plate, we may in practice always use th Rule in Art 5 for such joints; and, therefore, we gave it alone.

Rem. 2. When using these rules for other kinds of joint such as laps, or butts with *single* covers, remember that the rivets in such are in **single** shear; and, therefore, we can use Rule in Art 5 (for crippling) only when the diam is either **1.7 or more** times the thickness of plate. **If less,** use Rule above for **shearing;** all on the assumption that our foregoing coefs of crippling and shearing are used.

But the coef for tension must be changed for each kind of these other joints, to allow for the weakening effects of the bending shown at W, Fig 3, as deduced approximately from experiment. The writer believes that the following tension units will give safe approximate results without friction. **For double-cover butts,** double-riveted, 38500 lbs per sq inch, as adopted above **For double-riveted** laps, or one-cover butts, 28000. **For single-riveted** laps, or one-cover butts, 24000. But, as before remarked, no great certainty i attainable in riveting.

Rem. 3. A joint may fail by crippling without the facts bein known or even suspected, for it does not imply that anything **breaks,** bu merely that the joint has **stretched;** and this might not be detected even on a *slight* inspection of it. Still it might, and probably often has sufficed to endanger and even destroy both bridges and roofs by generating strains where none wer provided for.

RAILROADS.

TRACK.

GENERAL

1. Railroad track, as ordinarily constructed in the U S, consists of the following parts.

2. Rails. ¶ 83. The wheels of the rolling stock roll upon the heads of the rails, the wear of the wheel treads coming upon the upper surface of the heads, and that of the flanges coming upon the sides of the heads. The rails serv also as short girders spanning the spaces betw the ties, the heads there theoretically taking compression, the webs shear, and the bases tension; but, since the rails must act as *continuous* girders, the stresses in the heads and bases are necessarily reverst over each tie. The base of the rail servs also to distribute the load over the tie, and to afford a grip for the spikes. It offers the chief resistance against lateral flexure.

3. Joints, ¶¶ 145, etc. The rail ends are held together, and in line with each other, by means of rail-joints, splice-bars, or "fish-plates," which are clampt to the sides of the rails, near their ends, by means of bolts passing thru holes in both the plates and the rail-webs.

4. Spikes, ¶¶ 96, etc, driven into the ties beside the rails, hold the rails down to the ties by means of their overhanging heads which grip the edges of the rail bases; and their shanks resist lateral sliding of the rails on the ties.

5. Tie-plates, ¶ 135, etc, are largely used to distribute the rail pressures over a larger area of tie surface. They thus reduce the unit pressures on the ties, and the crushing effect of the loads.

6. Ties, ¶ ¶ 31, etc, serv to distribute, in and thruout the ballast, the vert loads and the hor thrusts deliverd by the rolling stock.

7. Ballast, ¶¶ 19, etc, not only takes the loads and transmits them to the roadbed or ground, but it usually has the additional function of prolonging the life of the ties by permitting water to flow away thru it from them.

8. Roadbed. The track proper, including the ballast, rests upon the ground, or roadbed; which must not only be of sufficiently firm material to hold the ballast and track up to level, but should also be so prepared as to drain away any water that may collect. For this purpose, ditches must often be provided alongside the roadbed, to carry off the water draind from the track, except where the road is on an embankment.

Specifications.

9. Thruout this article on Track, liberal use has been made of Specifications and other printed records of standard practice; and, where such data are quoted, or abstracted, the fact is indicated by the use of foot-notes, the proper foot-note mark being placed both at the beginning and at the end of each such paragraf or quotation, accompanied, in some cases, by figures denoting the year of publication.

The references most frequently made are the following:

BALLAST.

19. Stone. *Stone broken by artificial means into small fragments of specified sizes.* Broken stone is the universally preferd ballast for first-class conditions. The stones preferd, in approx order of preference, are *trap, granite* (or *syenite*, granite containing hornblende instead of mica), *limestone* and *sandstone*. *Screenings*, from the stone crusher, are commonly used in station platforms, and as ballast for side tracks; but they churn badly under the ties when wet. *Requirements*;—† "Trap rock, or an acceptable igneous or equally hard and suitable stone . . . . . regarded as standard material." Crushing stress $\nless$ 12,000 lbs/sq inch; limestone, $\nless$ 10,000 lbs/sq inch. Must be broken in cubical form. Must pass thru 3" ring, but not thru 1.25" ring.†

20. Gravel is cheap, when found near the work, and is easily applied. Sand and clay, in gravel, impede drainage; while sand and dust cause wear of tires and journals. *Requirements*. *Pebbles to pass a 2.5 inch ring, and be retaind on No. 10 screen. 1915.* † < 2.5 ins. 1908.†

21. Slag. Hard — . Blast furnace slag, deposited and coold in air. If it contains but little free lime, it is hard and glassy, and, when crusht, rivals broken stone as ballast material; but it sometimes affects the ties chemically. An excess of free lime leads to disintegration, and sometimes to setting, like that of mortar.

22. Slag. Granulated — . Slag into which, when molten, water has been injected. It consists of particles of very uniform size, about equal to that of very coarse sand grains. It is easily applied, and is used in yards and on side tracks. It is apt to slake, solidifying, and impeding drainage, if much free lime is present.

23. Cinder. Taken from locomotiv ash-pits. Cinder ballast drains well, but yields under heavy traffic. It sometimes affects the ties chemically, especially when wet. *Recommended for branch lines with light traffic, in sidings and yard tracks near point of production; as sub-ballast in wet, spongy places; as sub-ballast on new work where dumps are settling; and at places where the track heavs from frost. Make provisions for wetting down cinders soon as drawn. 1915.*

24. Burnt clay ballast drains well. It is easy to work, and stands well under light traffic. *Requirements*;—*Use black gumbo or other suitable clay free from sand or silt. Before establishing kiln, test material thoroly in a small test kiln. Burn hard and thoroly. Fuel should be fresh, and clean enough to burn with a clean fire. Keep enough fuel on hand to prevent interruption of burning. Cool the ballast before loading out of pit. Absorption of water $\ngtr$ 15% by wt. 1911.*

25. Chats. *Particles of quartz, about as large as wheat grains. They are the tailings from mills in which zinc and lead ores are separated from the rocks in which they occur.* Chat ballast works easily. It keeps down weeds, stands wet weather and holds its surface well; but, owing to lack of cohesion, it is easily shifted laterally. It is dusty under high speeds.

25a. Sand ballast is easily handled. It does not become plastic when wet; but it is heavd by frost, and, when dry, it is very dusty, and therefore annoying to passengers, and injurious to rolling stock, causing hot-boxes.

25b. Dirt ballast, in wet wether, becomes mud. The more sand it contains, the better.

25c. Gumbo. *A term commonly used for a particularly tenacious clay, containing no sand.*

25d. Chert. *An impure flint or hornstone occuring in natural deposits.*

RAILROADS.

TRACK.

GENERAL

1. Railroad track, as ordinarily constructed in the U S, consists of the following parts.

2. Rails. ¶ 83. The wheels of the rolling stock roll upon the heads of the rails, the wear of the wheel treads coming upon the upper surface of the heads, and that of the flanges coming upon the sides of the heads. The rails serv also as short girders spanning the spaces betw the ties, the heads there theoretically taking compression, the webs shear, and the bases tension; but, since the rails must act as *continuous* girders, the stresses in the heads and bases are necessarily reverst over each tie. The base of the rail servs also to distribute the load over the tie, and to afford a grip for the spikes. It offers the chief resistance against lateral flexure.

3. Joints, ¶¶ 145, etc. The rail ends are held together, and in line with each other, by means of rail-joints, splice-bars, or "fish-plates," which are clampt to the sides of the rails, near their ends, by means of bolts passing thru holes in both the plates and the rail-webs.

4. Spikes, ¶¶ 96, etc, driven into the ties beside the rails, hold the rails down to the ties by means of their overhanging heads which grip the edges of the rail bases; and their shanks resist lateral sliding of the rails on the ties.

5. Tie-plates, ¶ 135, etc, are largely used to distribute the rail pressures over a larger area of tie surface. They thus reduce the unit pressures on the ties, and the crushing effect of the loads.

6. Ties, ¶ ¶ 31, etc, serv to distribute, in and thruout the ballast, the vert loads and the hor thrusts deliverd by the rolling stock.

7. Ballast, ¶¶ 19, etc, not only takes the loads and transmits them to the roadbed or ground, but it usually has the additional function of prolonging the life of the ties by permitting water to flow away thru it from them.

8. Roadbed. The track proper, including the ballast, rests upon the ground, or roadbed; which must not only be of sufficiently firm material to hold the ballast and track up to level, but should also be so prepared as to drain away any water that may collect. For this purpose, ditches must often be provided alongside the roadbed, to carry off the water draind from the track, except where the road is on an embankment.

Specifications.

9. Thruout this article on Track, liberal use has been made of Specifications and other printed records of standard practice; and, where such data are quoted, or abstracted, the fact is indicated by the use of foot-notes, the proper foot-note mark being placed both at the beginning and at the end of each such paragraf or quotation, accompanied, in some cases, by figures denoting the year of publication.

The references most frequently made are the following:

* foot-note refers to American Railway Engineering Association; *Manual, 1915.*

† foot-note refers to Pennsylvania R R Specifications for the Construction and Maintenance of Standard Railroad; 1909, and other P R R Specfns, 1908-1914.

‡ foot-note refers to Union Pacific R R Co Rules and Regulations for the Maintenance of Way & Structures; 1909.

---

*Am Ry Engg Assn. †P R R. ‡U P R R.

Pecky tie. Made from a cypress tree affected with a fungus disease known locally as peck.

Pole tie. Made from a tree of such size that not more than one tie can be made from a section. Hewn or sawn on 2 parallel faces.

Quarterd tie. Made from a tree of such size that four ties only are made from a section.

Sap tie. Showing more than the prescribed amount of sapwood in cross-section.

Shakes. Separations of the wood fiber, due to the action of the wind.

Slab tie. A tie made from the first or outside cut of a log.

Slabbed tie. Sawd on top and bottom only.

Split tie. Made by splitting from a tree of such size that two or more ties can be made from a section.

Strict heart tie. Having no sapwood. See also Heart tie.

Substitute tie. Any tie other than a wood tie.

Switch tie. Tie of a set used to support a turnout.

Tapped tie. Made from a tree, the resin or turpentine of which has been extracted before felling.

Treated tie. A tie which has been subjected to a process designd to protect it from decay.

Wane tie. Squared and showing part of the original surface of the tree on one or more corners.*

General.

Dimensions, Bearing, etc.

32. A tie, acting as a continuous beam, serves to distribute the rail pressures to the ballast under it, and its dimensions should be such as to enable it to effect this distribution with tolerable uniformity Where a tie is more firmly supported at the middle of its length than near the rails, it is said to be *center-bound*. A tie of sufficient length transmits a fair proportion of the load to the ballast beyond the rails, correspondingly relieving the portion betw the rails. The thickness is commonly about 6 or 7 inches A 6-inch tie is hardly stiff enough for heavy traffic, especially where center binding is likely to occur; and is apt to be split by the spikes, since these, when driven, extend to very near the lower face. Since beam stiffness varies as the cube of the depth, the resistance to bending, in a 7-inch tie, is, to that in a 6-inch tie, as 343 to 216, or as 100 to 63. A thickness of 7 inches is rarely exceeded except with soft woods.

33. If more than about 40% of the rail length bears on the ties, the closeness of the ties interferes with tamping. The min clear distance, betw ties, is about 11 ins. With usual tie spacing, a tie thickness of more than 7 ins interferes with the work of tamping. With extremely wide ties, the full bearing value is not always utilized because such ties are seldom as thoroly tampt as are narrower ones.

34. When the spike enters the wood tangentially to the growth-rings, it is apt to split the tie.

35. Ties should be laid with the heart side down, in order that the growth-rings shall be in such position as to shed water.

36. Pole ties give a rail-bearing of heartwood, which resists abrasion better than sapwood and the bulging sides give additional bearing surface.

37. Cutting by rails. Moisture, collecting betw rail and tie promotes decay; and the load, aided by the undulatory motion of the rail, cuts away the decayd fibers. This *"rail-cutting"* is the principal cause of tie failures.

38. "Ties should be *protected* against failure from mechanical wear by means of *tie-plates* and *screw-spikes.*" A R E A Procs 1915 Vol 16, p 522.

"The use of treated ties wherever practicable is recommended."

---

*Am Ry Engg Assn. †P R R. ‡U P R R. See also Specifications p 780.

Woods.

39. Cedar is light, and resists decay well; but is easily crusht by the rail. On tracks having light traffic, or where protected by tie plates, cedar ties may last from 15 to 20 years. Sound dead cedar makes as durable ties as live cedar.

White oak ties are preferd. When well seasond, they hold the spikes very firmly; and resist rail cutting until the wood decays. Life, from 5 to 10 years; average of many roads, 8¼ years. A sawd and seasond white oak tie, 7 ins × 9 ins, 8 ft long, weighs about 185 lbs.

Rock oak is less tough than white oak. Its life is about the same.

Southern yellow pine ties last from 4 to 6 years in the south; and from 8 to 12 years in the north.

Chestnut ties last from 7 to 9 years. Chestnut checks badly in the sun; but holds spikes well, and is of medium hardness

Redwood is soft, but durable. Redwood ties, with tie plates, last from 10 to 14 years.

Wild cherry, locust and walnut ties last about 8 years.

40. Specifications. *Woods usable for ties *without preservativ* treatment: white oak family, long-leaf strict heart yellow pine, cypress (other than white), redwood, white cedar, chestnut, catalpa, locust (other than honey), walnut, black cherry.*

*Woods *preferably requiring a preservativ* treatment approved by the purchaser: red oak family, beech, elm, maple, gum, loblolly, short-leaf, lodgepole, western yellow pine, Norway, North Carolina pine and other sap pines, red fir, spruce, hemlock, tamarack.*

Switch-ties. †Usable *without preservativ* treatment: white oaks, black locust, black walnut, black cherry, longleavd pines. Usable *only after preservativ* treatment; red oaks, beech, hickories, hard maples, birches. 1913.†

See also under Turnouts, Part I, ¶¶ 128, etc.

Dimensions.

41. Classification. Dimensions from **Am Ry Eng Assn** Manual, 1915, p 59.

*Class	Thick-ness, ins.	Face width, ins.	Volume of one tie, in cub ft: Length, 8 ft, cub ft	Length, 8.5 ft, cub ft	Length, 9 ft, cub ft
*A	7	10	3.889	4.132	4.375
B	7	9	3.500	3.719	3.938
C	7	8	3.111	3.305	3.500
D	6	9	3.000	3.188	3.375
E	6	8	2.667	2.833	3.000

*** Permissible excess:**—in thickness, ½ inch; in width, 2 ins; in length, 1 inch. In pole ties with rounded sides, and in half-round ties, the face width may be < above (≮ 6 ins), provided cross-section area ≮ that corresponding to tabular dimensions. Thickness, ≮ 6 ins.*

Spacing.

42. Number of ties required under one rail length :—

	On main running tracks	On side tracks & branches	In yards and on sidings
33-ft rail	18‡	16‡	16‡
‡ If ties are < standard,	20‡		
† According to wt of traffic,	16 to 20†	16†	14†
30-ft rail	16‡	14‡	14‡
If ties are < standard,	18‡		

For shorter rails, use a proportional number of ties.‡

*Am Ry Engg Assn. †P R R. ‡U P R R See also Specifications p 780.

Maximum allowable distance between bearing surfaces. †Between *joint* ties, 11 ins; betw *intermediate* ties in main running tracks, 18 ins.†

Tie Timber Conservation.

43. On account of increasing scarcity and cost of tie timber, recourse is had (1) to chemical treatment, ¶ ¶ 44, etc., (2) to forestry, ¶ ¶ 54, etc, for the growing of trees for use as ties, (3) to reduction of wear on ties, as by tie plates, ¶ ¶ 135, etc., and (4) to the use of ties of other materials, as steel or reinforced concrete, ¶ ¶ 61, etc.

Preservativs.

44. The economy of treated ties lies not only in their increast length of life, but in the reduction of the labor of tie renewals and of the resulting disturbance to the embedment.

45. Inferior timber. Chemical treatment, and the use of tie plates, permit the use of timbers not otherwise suitable, and of sound dead timber.

46. Steaming. For thoroly air-seasond ties, preliminary vacuum ≮ 24 ins mercury, maintaind ≮ 10 mins. Preservativ then admitted without breaking the vac.*

* For ties not thoroly air-seasond, a pressure of 20 lbs per sq inch must be attaind within from 30 to 50 mins, and maintaind (not exceeded) from 1 to 5 hrs, depending upon character and condition of timber. A vent must be kept open, in bottom of cyl. or in drain therefrom, for escape of air and condenst steam. After steaming, vacuum ≮ 24 ins of mercury at sea level (corresponding degs of vac at other altitudes) maintaind for half hour. Preservativ then admitted without breaking vac.*

* Unseasond ties, which are to be creosoted, may be given long steaming or seasoning in hot creosote oil.*

47. *Zinc chlorid treatment (Burnettizing). See also p 1135. Solution, heated to ≮ 140° Fahr, to be admitted without otherwise reducing vacuum. Wood must absorb 0.5 lb dry soluble chlorid per cu ft Solution must be only strong enough to give this absorption, and ≯ 5%. Steam pres maintained in steam coils of machine during treatmt.*

* Chlorid must be slightly basic, without free acid; iron ≯ 0.25%.*

* Sample borings to be taken, from time to time, from ≮ 6 ties treated in the same run. Bore-holes to be tightly and completely closed with creosoted plugs.*

* Ties must be allowed to dry (in order to harden surface) before placing in track.*

48. *Zinc chlorid, tannin and glue Treatment. See p 1135. Zinc chlorid as above. Solution then blown or run off. Ties draind 15 mins. 2% tannic acid solution (6.67 lbs of 30% extract of tannin to 100 lbs water) applied half hour under pres of 100 lbs/sq in Tannin solution run off, and 1% glue solution (2.1 lbs glue, containing 50% gelatin, in 100 lbs water) applied for half hour under same pres.*

49. *Creosote. See p 1134. Coal-tar creosote oil; at 38° Centigrade, completely liquid, and ≮ 1.03 sp grav; ≯ 3% water; heated to 160° Fahr. Pressure, 100 lbs/sq inch.*

50. *Zinc-creosote Emulsion. Emulsion to contain ≮ 10% creosote. Heated to ≮ 140° Fahr. Pres, 100 lbs/sq inch. Wood to retain an avge of 0.4 lb dry soluble chlorid and from 1.25 to 1.5 lbs creosote, per cub ft. Zinc-chlorid solution not stronger than 3.5%; to contain ≯ 0.25% iron.

***Am Ry Engg Assn. †P R R. ‡U P R R. See also Specifications p 780.**

51. * Two-injection Zinc-creosote. Zinc solution not stronger than 5%; heated to ≮ 140° Fahr. Wood to receiv 0.3 lb dry soluble chlorid per cub ft. Solution then run off, creosote oil, 140° Fahr, immediately admitted and pres applied; 3 lbs oil per cub ft. Water, exceeding 6%, to be removed.*

52. *Life.* Creosoted pine ties last about 15 yrs, creosoted oak 18 yrs, and creosoted beech 20 yrs, in main track; and giv subsequent servis, about one third as long, in side track.

Seasoning, etc.

53. Unseasond ties to be *piled for seasoning;* green ties separate from partly seasond ties; all resting on treated stringers, with ≮ 6 ins air space under lowest tier; top tier laid sloping, to form a water shed. Betw piles, leave alleys, 4 ft clear width in one direction, 1 ft in the other. Required degree of seasoning to be determind by test, finding that weight at which each wood will best receive the treatment. Ties threatend with checking must be protected by S irons, bolts or other devices Adzing or boring, for tie-plates or screw spikes, must be done before treatment.

Forestry.

54. Culture of timber should be undertaken only by expert foresters. We here outline only fundamentals of general interest to engineers.

55. *Felling season.* Whatever season is selected for felling the trees, the ties made from them should have at least six months for seasoning before going into track. However, the seasons for cutting and for tie renewals come so close together, that this is difficult to observ without holding the ties over a year. * Timber cut preferably from Oct to Mar;* †Sep to Mar.†

56. *Bark* should be peeld soon after felling, to hasten evaporation and to prevent "souring". Placing ties in track, with bark on, not only hastens decay, but renders the ties more inflammable * Bark to be removed from all ties before their delivery to the Co. 1915.*

57. *Methods of cutting* trees and of cutting ties from trees are usually wasteful. Wood is frequently lost by leaving unnecessarily large stumps, and thru failure to follow as far up as possible into the tree; large trees sometimes affording ties from their branches. Much is frequently lost by cutting trees which are only large enough to afford pole ties (one from each section); whereas, by waiting five or ten years, two ties could be obtaind from a section.

58. *Forestation.* The early practice was to plant only rapidly growing trees; but it has been found that other important considerations (such as liability to attack by parasites, low strength or short life in the track, etc) may well lead to the selection of slower-growing trees. Each tract of available ground, too, should be carefully studied as to what species it can best produce. It is frequently better, also, to develop existing imperfect timber lands, than to attempt complete reforestation from the seed.

59. *Fire prevention* may frequently warrant considerable expenditures for patroling, especially in dry wether.

Dating Nails.

60. *Iron or steel, evenly galvanized, ¼ inch diam, 2½ ins long, head ⅝ inch diam, stampt 1/16 inch deep with 2 numerals ⅜ inch long, designating the year. Nail driven in upper face of each treated tie, 10 ins inside of rail, on line side of track, on the day of laying. Each treated tie stampt also with year, on both ends, at treating plant, before treatment *

*Am Ry Engg Assn. †P R R. ‡U P R R. See also Specifications p 780.

Substitute Ties.

General.

61. A substitute tie is "any tie other than a wood tie." Am Ry Eng Assn Procs, 1915, Vol 16, p 522; Ties Committee Report.

62. Owing to the rapidly increasing scarcity of suitable timber, substitute ties are largely used in Europe; and their use, experimentally or in service, has been activly taken up by many American railroads, including some important systems.

The use of substitute ties involvs so radical a change in R R practice that considerable experience in their use will be required, to determin satisfactorily their relativ advantages and disadvantages.

63. Owing to their uniformity in cross-section, in strength, and in bearing surface, substitute ties (and, especially, steel ties) hold track to better line and surface, and the rail wear is more uniform. Wood ties, even those of the same wood, vary in quality when laid, compressing unequally under a given load, and they deteriorate rapidly and unequally under exposure. When fully ballasted, steel ties furnish a smoother-riding and quieter track.

Substitute ties are heavier than wood ties and more expensive in first cost. It has been found difficult to provide satisfactory rail-fastenings. See Screw-spikes. ¶¶ 107, etc.

With the growing use of electric signal circuits, the matter of insulation has become one of importance; and, in general, substitute ties offer greater difficulties in this respect.

Substitute ties, laid alternately between wood ties, hasten the deterioration of the latter.

Other things equal, the greater weight of substitute ties tends to greater stability in track.

Substitute ties are either steel, concrete (usually reinforced) or composit (composed essentially of two or more materials). Am Ry Eng Assn, Procs, 1915, Vol 6, p 522. Ties Committee Report.

Steel Ties.

64. Types. In Europe, much use has been made of *"longitudinals"* or steel *sleepers,* placed under, and parallel with, the rails, and of inverted cast iron "bowls", placed opposit each other, under the rails, at intervals, and connected by ties extending across the track; but, in America, practice and experiment with substitute ties have been practically confined to *cross ties* having functions generally similar to those of the wooden tie.

65. The earlier experiments were with *inverted trough ties;* and such ties are still used under light traffic; but the *inverted-T type,* represented by the Carnegie steel tie, ¶¶ 70, etc, is much the most largely used.

66. A flat bottom, as distinguisht from one having downward projections, facilitates tamping.

67. The fastenings consist generally either of bolts and clips, or of wedges. They should permit adjustment for differences of gage and of rail section.

68. The cost of steel ties is usually from 4 to 6 times that of good oak ties; but the steel should have a longer life than the oak tie, and considerable scrap value when no longer available for tie purposes.

69. Merits and demerits. Steel ties *hold track* absolutely *to gage.* Owing to their uniformity in cross-section, in strength and in bearing surface, they *hold track* to better *line and surface;* and the rail wear is more nearly uniform than with wooden ties.

In the absence of sufficient data from experience, their **life** is usually estimated at two or three times that of wood ties.

Owing to their small metal cross-section, steel ties require *more ballast* than do wood ties of the same external dimensions.

When steel ties have been puncht with square holes, *splitting* has been found to begin in the corners of such holes.

Steel ties are exposed to *deterioration from rust*, especially in damp situations, such as tunnels, and under brine drippings from refrigerator cars. *Protectiv coatings* have been used; but these are difficult of application to ties in service.

The all-steel tie is a satisfactory substitute under heavy medium-speed traffic. It is durable. Line and surface can be maintaind (see Maint costs, ¶ 73). It has sufficient resilience, and can be insulated. The fastenings are usually inadequate. Am Ry Eng Assn Procs 1912, Vol 13, Comm on Track.

70. Carnegie. Figs 4 represent the steel tie of the Carnegie Steel Co. *A*, plan of whole tie; *B*, side elevation; *C* and *D*, enlarged cross-secs at *m n* and *o p*, Fig *A*, respectivly; *E* and *F*, plan and elevation showing rail and standard fastenings In rock or coarse gravel ballast, and on descending grades under heavy traffic, the lower flange may be crimpt, as shown in *A*, *B* and *D*; but this interferes with ballast tamping. The tie may be puncht for two weights of rail.

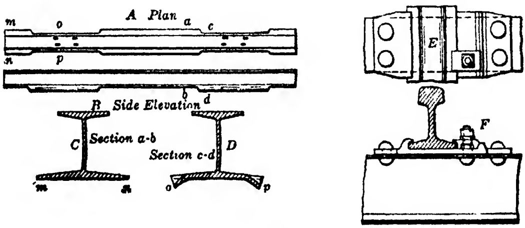

Fig. 4.

Dimensions, in ins, etc

Section	lbs/ft	Tie, 8.5' long, wt, lbs	Depth	lower flange width	upper flange width	web thickness
M 24	9.5	81	3	5	3	13/64
M 25	14.5	123	4¼	6	4	1/4
M 21	20	170	5½	8	4½	1/4
M 28	27.8	236	6½	10	5	5/16

The fastening allows about ⅛ inch play, vert and hor, in the rail.

71. *Insulation* consists of ⅛ inch fiber, of which there is (1) a plate betw the steel tie plate shown in Fig 4 *F* and the top of the tie, (2) a washer under the rivet washer, and (3) a bushing around the rivet shank.

72. *The first* Carnegie steel ties were placed on the Bessemer & Lake Erie (a Carnegie-controlled road) in 1904. They have stood well under heavy freight traffic at moderate speeds. Under high speeds, their rigidity has been found objectionable.

Owing to restriction of movement betw rail and tie, they have been found to *reduce creeping*.

In renewing, it has been found that a gang can handle more of them than of wood ties, in a given time.

As a *protection against rust,* they have been dipt in hot tar, at a cost of 5 cts each.

The insulation (see ¶ 71) has been found to work well while in good condition; but, in 3 or 4 years, the fiber plates wear, and the bolts become loose in consequence. See ¶ 73. Many have been removed upon the installation of automatic signal systems.

The cost may be taken at from $2.00 to $2.60 per tie; with 20 cts additional, per tie, for fastenings. This is rather more than double the cost of wood ties.

73. *On the Pittsburgh & Lake Erie,* Carnegie steel ties, with bolt-and-clip fastenings, were laid in new limestone ballast, Aug 1907, on 4400 ft of main-line freight tracks, speeds to 30 miles/hr. Maintenance costs as follows.

	1908	1909	1910	1911	1912	Total	$/mile per yr
White oak	$ 417	95	128	116	94	850	204
Carnegie steel	$ 280	153	428	184	348	1393	334

In 1911, the white oak tie track was renewed once; the steel-tie track three times. The first 17 fiber plates gave out, cut by rail base; 20 bolts loose in steel-tie clips. In 1912 the cost included $102 for renewing 1000 fiber plates. "Practically no signal trouble whatever"

Other roads have reported less trouble in track maintenance than with wood ties.

74. Annual *loss of weight,* due to rust, attrition, etc., has been variously reported, from diff roads, as ranging from 0.7 lb/tie, or 0.40%, in slag or gravel, to 4.5 lbs/per tie, or 2.55% in cinder. After seven years of service, they have shown little external evidence of corrosion. Laid on the Pittsburgh, Shawmut & Northern in 1907, and reported as giving "eminent satisfaction" in 1913, they appeared to be "failing quite rapidly of late" in 1915.

Carnegie steel ties, laid on the Erie in April 1909, were found rusting and *depreciating in salt air* in 1913.

75. On the Duluth, Missabe & Northern, they gave great satisfaction as substitutes for wooden ties which had given great trouble on *swampy ground.*

76. Where *wedge fastenings* are used, trouble has been experienced in keeping them tight.

77. On the Lake Shore & Mich Southern, near Sandusky, under *heavy traffic at high speed* in 1905-6, Carnegie steel ties were laid, with a wooden block fastend on top of the upper flange under each rail at each tie, at a cost, complete, of $2.25 to $2.50 per tie. The blocks were fastend by bolts, passing thru metal U-straps under the tie. This, by confining the wood fibers, increast the pulling resistance of the spikes. Up to 1908, these ties gave no more trouble than wood in regard to insulation; but trouble with the insulation was experienced later; and all of the ties had been removed, in 1915, on account of softening of the timber.

78. The L S & M S, near Toledo, in 1907, laid Carnegie steel ties from which the upper flanges had been removed, and to which two wooden blocks, one on each side, had been bolted thru the tie-web under each rail, and bearing on the tie flanges; the *rails being spiked to the wooden blocks* as to a wooden tie.

In 1910 these were reported "in fine shape", and to have "held surface and line as well as any track on the L S & M S."

79. *The inverted-trough section,* owing to its downward projections, is unfavorable to tamping. Hence, it is made shallow, and this renders the tie weak vertically. It is still used under light traffic, as in industrial, construction and mining tracks, etc.

80. Figs 5 show two **forms** of the **Carnegie steel** *trough* or *channel tie*, with their fastenings.

The following sections are furnisht, **dimensions in inches**:—

Section	lbs per ft	Depth	Extreme width	Web thickness	Fig
M 19	2.5	5/8	4	9/64	5 *a*
M 26	3.2	13/16	4 15/16	1/8	5 *a*
M 20	6	2	6	3/16	5 *b*
M 27	9	2 1/4	7	1/4	5 *b*

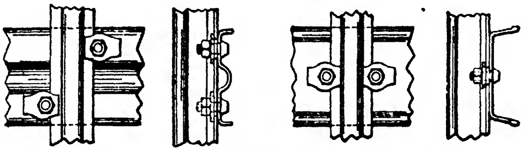

Fig. 5.

For mine work, the clips are prest out of, or riveted to, the horizontal portion of the tie itself.

In 1900-1901, *heavier* Carnegie steel trough ties, weighing 199 lbs each, were installed *on the Bessemer & Lake Erie.* After 8 years' service, they had lost 2.5 lbs/tie/yr, = 1 25%/yr, and showd no appreciable wear under the rails.

Concrete and Composite Ties.

81. Merits and demerits. Concrete and composite ties are usually heavier than steel ties for the same service; but less expensiv. Months are required for proper set of concrete. Conc surfaces, if not protected by metal, are vulnerable to blows, as in derailments. It is difficult to provide satisfactory fastenings. Their weight and the roughness of their surfs are favorable to lateral stability, and the absence of downward projections is favorable to tamping and to removal. The conc itself furnishes tolerable insulation for signal circuits; but there is danger of contact thru the reinforcing metal.

They have generally faild, by reason of brittleness, excessiv weight (rendering handling difficult) and deterioration of the filling when this is of asphalt mastic.

Am Ry Eng Assn Procs, 1912, Vol 13. Report of Tie Committee.

82. The following **records of experience** with composit ties may be of value as indicating what has been done and what should be avoided, in making such ties.

82a. 1 : 2 : 3 concrete, reinforced by 2¼ inch longitudinal wrot iron pipes and a sheet 5 × 8.5 ins of heavy wire netting, under each rail. Weight, 321 lbs; fastenings, 35 lbs additional. $1.50 to $1.75 each.

82b. Trapezoidal, with batterd ends. Reinforced by coil of wire mesh, No 16 gage, ½ inch pitch, and by ½" rods. Cost $1.50 each. In Scully yard, Penna Lines West Installed 1906, in cinder ballast, under heavy slow traffic. Rails spiked thru tie plates to wood blocks; 16 ties to 30-ft, 85-lb rail. Crumbled under rails. Bolts loosend. Rail creeping turnd clips around, unclamping rail.

82c. An inverted 65-lb scrap rail, imbedded in concrete. Batterd ends. Narrowd, at center of track, to width of rail flange. This narrowing prevents lateral movement. $0.95 + fastenings and 180 lbs scrap rail.

L S & M S. Still in track, in good condition. R R Gaz, 1908 May 1, p 594.

Pg Ft W & C. Placed 1903. All removed 1906. Conc broke away from steel.
Placed 1903. Light medium-speed traffic. Broke. Removed 1903.

"The most successful of all the conc ties I have seen, and under favorable conditions it certainly makes a fine looking track." Stands derailments well. Rock ballast may be too rigid. Gravel may be better. Am Ry Eng & M W Assn, Procs 1907, Vol 8, p 465.

A R E M W A Bulletin 108, Feb 1909, p 174 givs favorable accounts from L S & M S, and unfavorable accounts from Penna Lines, Chicago Junction, Lake Erie & Western.

RAILS, &c

General

83. Weight. Rails weighing from 75 to 85 lbs/yd are in common use on lines of heavy traffic; but 90-lb and 100-lb rails are used under extremely heavy traffic. Still heavier rails have been rolled, but difficulties in their mfr militate against their extensiv use.

84. Length, standard—, *33 ft at 60° Fahr; 1915.* †33 ft at 60° Fahr 10% of order accepted in lengths of 30 ft, 27.5 ft and 25 ft. Variation of ¼ inch from specified lengths allowd. 1912.† Rails 60 ft long are sometimes used at highway crossings, etc, to avoid the occurrence of joints under the planking and paving, where they would be inaccessible for tamping. They are used, also, in track in general, to reduce the number of joints.

Behavior

85. Wear of rails is most rapid on sharp *curvs,* where the flanges grind against the side of the rail head. It decreases as the sharpness of curvature decreases. On curvs, the wear of the top of the rail head is very small in comparison with that of the side of the head.

86. *On tangents,* rail wear occurs principally on the top of the head, and is due to the tractiv effort of the loco drivers and to the slipping of wheels of unequal diams fastened to the same axle.

87. *On grades, and at stations,* owing to necessary increase of tractiv effort, both in starting and in stopping, rail wear is greater than on level track or betw stations.

88. The *allowable limit* of wear of top of rail heads is generally taken at abt ⅝ inch; but, before this limit is reacht, the rail must, in many cases, be removed on account of roughness of running surface, causd (1) by slivering of the metal, or (2) by bending and excessiv wear at the rail ends, especially at the receiving end of the rail in double track.

89. Life of rails is variously estimated at from 100 to 250 million tons of traffic past over them, depending partly upon alinement and grades, and upon condition of track.

90. *Under heavy traffic or on sharp curvs,* the rails may have to be turnd end for end, or renewd, as often as once in two years. On rapid transit lines, renewals of rails on curvs must in many cases be made much more frequently, in some instances oftener than annually.

91. "Corrugation" of rail heads has become very annoying and expensiv, especially on curvs and in track traverst by electric rolling stock. It consists of a series of low worn spots on the rail head, the spots being usually some fraction of a foot apart. No agreement seems to have been reacht as to the cause, in spite of numerous theories put forward. A plausible theory is that, since, in rounding a curv, one wheel or the other of a pair must slip longitudinally, the slipping may take place in jerks, the truck frame and the axle being alternately twisted slightly and releast.

The low fric coef of slipping would permit an appreciable sliding (and consequent excessiv wear) along the rail top before one wheel caught up with the other; and then, when rolling of both wheels was re-establisht, the high static fric coef of rolling would prevent slipping until the curv had been traverst far enough to compel slipping once more. Wheels, traversing a curv, must slip sidewise as well, and this, like the longitudinal slipping, may take place in jerks simultaneous with the longitudinal slipping; and these slips probably resolv themselves into a diagonal slip. An other theory, based largely upon the observation that corrugations vary with tie-spacing, etc., attributes corrugation to vibrations of the track and ground.

Manufacture.

Ingots kept vertical (in the pit-heating furnaces, **W, M, C**) until ready to be rolled, or until the metal in the interior has had time to solidify, **A**; use of "bled" § ingots forbidden, **A.**

"**Discard.**"¶ to be sheared from end of bloom formed from top of ingot, sufficient to insure sound rails, **R**: subject to agreement, **M**; ≮ 25%, more if necessary until steel appears solid, **W, C.**

Shrinkage. Number of passes and speed of train to be such that, on leaving the rolls at the final pass, temp of rail shall be ≯ to require, at the hot saws, a shrinkage allowance, for 33 ft 100 lb rail, of 6.5 ins, **R**; 7⁵⁄₁₆ ins, **M**: 6⁷⁄₁₆ ins, **W, C**: ⅛ inch less for each 10 lbs decrease in section, **R**: ¹⁄₁₆ inch less for each 5 lbs, **W. M, C**: allowance decreased 0.01 inch, **M** (¹⁄₁₀₀ inch, **W, C**) for each second of time between leaving finishing rolls and sawing, **W, M, C.**

Cooling. Rails must not be artificially cooled between "leading" and "finishing" passes, **R**; or after leaving the finishing rolls, **R, C**: between finishing pass and hot saws, **W, M**; or held, before sawing, to reduce temp, **R, C.**

Brand. Maker's name, weight of rail, month and year of mfr, rolled in raised letters on web; number of blow stamped on web where it will not be covered by splice bars, **A**: also "A" on rails from top of ingot, then "B," "C," etc, consecutively; "A" omitted where top discard ≮ 20%; "A" rails shipped in separate cars, **R**; open hearth rails to be marked "OH," **R.**

Straightening. Rails on hot beds to be protected against contact with water or snow, **R**: rails, varying > 5 ins, **M, C** (> 3 ins, **W, R**) from a straight line in any direction, on reaching cold-straightening machine, or having short kinks, to be classed as 2nd quality, **A**; and so marked, **R**: and so stamped, **W, M, C**: supports of rails in gagging press ≮ 42 ins apart, **R, W, M**: supports to have flat surfaces, **R**: finished rails to be straight in line and surface and smooth on head, final straightening to be done cold, sawn square on ends, variations ≯ ¹⁄₃₂ inch; saw burrs removed and ends cleaned before shipment, **A.**

Permissible Variations.

In section. In hight, ¹⁄₃₂ inch, **R**: ¹⁄₆₄ inch less, ¹⁄₃₂ inch greater **W, M, C**; in flange width, ¹⁄₁₆ inch, **A**: rail must conform to fit of splice bars, **R, W, C.**

In weight. 0.5 % on entire order; rails accepted and paid for by actual weights, **A.**

In length. 0.25 inch, **A.** Standard length, 33 ft, **A**: 10 % of order accepted in lengths of 30, 28, 26 and 24 ft, **R**; in lengths varying, by even feet, to 27 ft, **W, M, C**; all No 1 rails < 33 ft to be painted green "on the end," **W, M**; on both ends, **R, C.**

Tests.

Drop test. "Tup," 2000 lbs, **A**; striking-face radius, 5 ins, **R**; ≯ 5 ins, **W, M, C**; anvil block, 20,000 lbs, **R**; ≮ 20,000 lbs, **W, M, C**; supports to be part of, or firmly secured to, anvil, **A**: test piece, length, ≮ 4 ft, ≯ 6 ft, **A**; test piece to be taken from top of ingot, **A**: placed head upward, on supports (5 ins top radius, **R**), 3 ft apart, **A**; one drop test from each blow, **R, W**, (for Bessemer, **C**); every fifth blow, **M**; two from each heat for basic open-hearth, **C**; hight of fall:

lbs per yd	60–80	90–100	45–55	55–65	65–75	75–85	35–100	
fall, ft	16	17 18, **R**;	15	16	17	18	19,	**M**;

lbs per yd	70–79	80–89	90–100;
fall, ft	18	20	22, **W, C.**

Temperature of test pieces between 32° and 100° F, **R.** Report to state atmospheric temp, **W, M, C.**

---

§Ingots from the interior of which the liquid steel has escaped, **R.**
¶Metal from top of ingot, whether cut from bloom or from rail, **R.**

Acceptance and Rejection.

If piece breaks without showing "pipe" or physical defect, all rails from that heat are rejected, **R.**

If broken piece shows "pipe" or physical defect, the top rail from each ingot of that heat is rejected, and the inspector selects a piece from a rail not from top of ingot. If this piece breaks, the rest of the rails of the heat are rejected; if not, they are accepted, **R.**

If first test piece does not break, it is tested to destruction. If it then shows "pipe" or physical defect, the top rail from each ingot is rejected, the rest accepted. If not, all the rails of the heat are accepted, **R.**

If test piece breaks, two additional tests are made of other rails (taken from top of ingot, **W, M, C**) from same blow. If either additional test fails, all the rails of the blow are rejected. If not, all are accepted, **W, M, C.**

92. Manganese steel rails, both cast and rolled, and rails of other special steels, are used on curvs of city rapid-transit lines. Steam roads have used such rails but little, if at all, altho manganese steel is largely used in switch and crossing frogs. Some early manganese cast steel rails, used on curvs in Boston subways, altho ten times more expensiv than ordinary rails, lasted twenty and more times longer.

Where a more durable rail is used, rail renewals are less frequent. On the Boston curvs mentiond, ordinary rails required renewal twice in about 3 months.

Rail Sections.

Railroad Spikes.

t

96. The hook-headed spikes *t*, commonly used for confining rails to the cross-ties, vary within the limits of the following table; the lightest ones for light rails on short local branches; and the heaviest ones for heavy rails on first-class roads. The spikes are sold in kegs usually of 150 lbs. For the weight of spikes of larger dimensions, we may near enough take that of a square bar of the same length. What is saved at the point suffices for the addition at the head.

Dimensions, etc.

Size in ins. Length	Side	No. per keg of 150 lbs.	No. per 100 lbs.	Size in ins. Length	Side	No. per keg of 150 lbs.	No. per 100 lbs.

¶ *I* = inertia moment, in biquadratic inches. See p 468.
‖ *X* = section modulus in square inches. See p 473.
†† *R* = mean radius *in inches*
= area in sq ins ÷ periphery in inches;

97. Quantity per mile. A mile of single-track road, with 33-ft rails, and 18 ties per rail length, with 4 spikes to each tie; will have 160 rail-lengths, and 2880 ties, and 11 520 spikes, or about 39 kegs of 5½ by 9/16, which weighs a trifle more than ½ lb/spike.

98. *But an allowance must be made* for gard rails at road-crossings, which we may assume to be 33 feet wide, or the length of a rail. A gard will usually consist of 4 extra rails for protecting the track rails, and spiked to the 18 ties by which said track rails are sustaind. Consequently such a crossing requires 18 × 8 = 144 additional spikes. For turnouts, sidings, loss, etc, we may roughly average (allowing for about 1 mile of extra track in the shape of turnouts and sidings in each 15 miles of road) 900 spikes more per mile; thus making in all (assuming one road-crossing/mile) 11.520 + 144 + 900 = 12,564 spikes/mile, or say 43 kegs of 150 lbs each.

99. Adhesion of Spikes. Professor W. R. Johnson found that a plain spike .375, or ⅜ inch square, driven 3⅜ ins into seasond Jersey yellow pine or unseasond chestnut, required about 2000 lbs force to extract it; from seasond white oak, about 4000; and from well-seasond locust, about 6000 lbs. Bevan found that a 6-penny nail, driven one inch, required the following forces to extract it: Seasond beech, 667 lbs; oak, 507; elm, 327; pine, 187.

100. Very careful experiments in Hanover, Germany, by Engineer Funk give from 2465 to 3940 lbs (mean of many expts, about 3000 lbs), as the force necessary to extract a plain ½ inch square iron spike, 6 ins long, wedge-pointed for 1 inch (twice the thickness of the spike), and driven 4½ inches into *white or yellow pine*. When driven 5 ins the force required was about 1/10 part greater. Similar spikes, 9/16 inch square, 7 inches long, driven 6 inches deep, required from 3700 to 6745 lbs to extract them from pine; the mean of the results being 4873 lbs. In all cases *about twice as much force was required to extract them from oak*. The spikes were all driven *across* the grain of the wood. Experience shows that when driven *with* the grain, spikes or nails do not hold with much more than half as much force.

101. Jagged spikes, or twisted ones (like an auger), or those which were either sweld or diminisht near the middle of their length, all proved inferior to plain, square ones. When the length of the wedge point was increast to 4 times the thickness of the spike, the resistance to drawing out was a trifle less.

102. When the length of the spike is fixt, there is probably no better shape than the plain square cross-section, with a wedge-point twice as long as the width of the spike.

103. Behavior. The hook-head spike is, in time, workt upward by the undulatory motion of the rail. In being driven, it crushes the fibers of the wood; so that (particularly in soft woods) they fail to withstand the lateral pressure of the spike. The spike hole is thus so enlarged that the spike loses its hold; and water, entering the hole, hastens decay.

104. Steel. *Finisht spike must show no sign of fracture (a) when bent back on itself thru 180° and hammerd down, (b) when head is bent backward cold, (c) when body is twisted cold thru 1.5 turns.*

Max permissible variation, from dimensions shown: thickness, 1/32 inch; length under head 0 inch less, ¼ inch more; thickness of head, 1/16 inch; angle of hook, 1°.

105. Holes, 1/16 inch less in diam than the thickness of the spike, are sometimes bored for the reception of the spikes. They prevent the crippling of the wood fibers by the spike, and thus increase the resistance of the spike to vert pull, and that of the wood to the lateral thrust of the spike.

---

*Am Ry Engg Assn. †P R R. ‡U P R R. See also Specifications p 780.

106. Tie-Plugs. Wooden tie-plugs, shaped like the body of the spike, and driven into the spike holes when the spikes are pulled, prevent decay by excluding water. If a spike is afterward driven into the same hole, the plug increases its hold in the tie. †Air-dried wood; cut longitudinally with grain; opp sides parallel; cut square at driving end; 4.5 ins long; 11/16 inch sq; chisel-pointed for 0.5 inch at one end. 1910.†

Screw-Spikes.

107. Screw-spikes are expensiv and time-consuming (see **Costs,** ¶¶ 118, etc) in installation, and in subsequent renewals or other changes; but they prolong the useful life of the tie perhaps two to three-fold, and hold the track in better shape and for a longer time, thus rendering renewal less frequent. Their use may thus reduce *total* installation and *total* maintenance costs.

On the Lackawanna, 5 years' use necessitated no increase in the number of sectionmen per mile

Resistance. In general, screw-spikes offer two or three times the resistance of cut spikes to direct pull, and greater resistance to lateral thrust, and they maintain these resistances much longer. They thus reduce liability to derailment, and damage resulting from derailment.

108. Corrosion may so reduce the size of the head as to cause loose fit in the wrench socket, and thus render removal difficult. A taperd head (Fig 8) obviates this difficulty to some extent; but machine driving (see ¶¶ 130, etc) causes alternate engaging and slipping in the socket and rounding of the corners During 5 years' use on the Delaware, Lackawanna & W'n, no screw-spike was found rusted within the tie.

When the head is broken off, removal is generally impracticable.

109. A raisd letter or device, on the top of the head, betrays any use of the hammer in driving

110. Variations in rail section increase the difficulty in the use of screw-spikes.

111. Behavior. In general, the screw-spike, by holding rail and tie in contact, compels them to rest or move (as the case may be) together. When they move together vertically, the tie may exert a prejudicial churning or a beneficial tamping action upon the ballast, according to the character of the ballast and other circumstances. Some roads prefer to hold tie-plate fast to tie, and allow some play betw rail and tie-plate.

112. As the hole must always be bored in advance, the screw-spike is *less likely to split the tie* than is the cut spike driven in an unbored tie.

113. Owing to compression of tie and to increasing closeness of contact betw tie, tie-plate and rail, in service, newly driven screw-spikes *must usually be tightened* once or twice, at intervals of some months; but thereafter they retain their hold with little or no further attention.

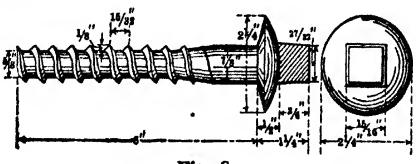

Fig. 8.

114. Dimensions. Fig 8 represents the standard screw-spike of the D L & W R R, 1915. Dimensions in inches. Other designs show head flat on the under side, and without taper. See ¶ 115.

114a. The design, once adopted, should not be changed, as any change would greatly increase the difficulty of the use of screw-spikes.

115. In order *to protect the spike against bending* under lateral pressure, its head, on each side of the spike, must be well supported, as by properly formd clips, or lugs on the tie-plate, or by fitting the spike-head to the rail-flange.

116. Dowels. Hardwood or metal dowels or plugs, driven or screwd into holes prepared for them, and tapt internally for the screw-spike thread, are advantageously used, especially in soft-wood ties, either when the spikes are first driven, or after the spike has begun to loosen. If of wood, they are treated before insertion. The large hole, required for the dowel, necessarily weakens the tie somewhat. The dowel acts as a colum, and thus diminishes indentation of the tie. If of wood, the fiber is vert. and, after driving, the top of the dowel is cut off flush with the upper surf of the tie. The dowels are indefinitely renewable during the life of the tie.

117. The Thiollier steel coild spring or helix has been used as a dowel on several Am RRs and in France. Difficulty has been found in placing and in removing the helix.

117a. The Lakhovsky cast-steel split-sleeve, screwd into the tie, and expanding as the spike is driven, has been used in France.

118. Costs. *Screw-spikes* cost from 2 to 3 cents each, or 2 to 3 times as much as cut spikes. *Hardwood dowels,* tapt outside and inside, 1.5 cts each.

119. The costs of the several **operations involvd** vary widely with conditions. Thus, *placing* 2 tie-plates, boring 4 holes and driving 4 screw-spikes, cost 13.74 cts /tie when boring and driving was done *by hand*; 4.89 cts on *scatterd work with a machine* having two drills and one driving tool; and 2.9 cts on *continuous work with machine* having two drills and two driving tools.

120. *Boring.* Mr. J. W. Kendrick, Am Ry Eng & M W Assn, Procs 1910, Vol 11, Part 1, p 625, says:—"A proper machine at the treating plant will bore and plug 600 ties with 8 plugs each, per day of 10 hrs, at a cost of 3.5 cts/tie" = 0.4375 cent/plug; but, in estimating cost/mile, Mr. Kendrick takes "boring ties for, and driving, 24,000 dowels" (8 per tie) at 1 cent each, presumably for field work.

121. Use. Screw-spikes have long been quite generally used on important lines in Europe, and they are now largely used upon a few such lines in the U S, notably upon the Santa Fé and the D L & W.

122. "Ties should be protected against failure from mechanical wear by means of tie-plates and screw-spikes." Report of Committee on Ties. Am Ry Eng Assn, Procs, 1915, Vol 16, p 522.

123. Tie-plates. The use of tie-plates without bottom flanges (see ¶ ¶ 135, etc) is generally considerd essential to satisfactory service with screw-spikes. See ¶ ¶ 115 and 111.

124. The tie-plate is sometimes screw-spiked to the tie, and the rail held by cut-spikes driven thru slots in the tie-plate.

125. Joints. During the first 2 years (1910-11) of its use of screw-spikes, the D L & W used malleable iron joint plates, and the angle bars were slotted for cut-spikes. One screw-spike was used on the outside of the outer angle bar. Later, all joint plates have been rolled, and screw-spikes used in angle bar slots, with one extra screw-spike on outside of the angle bar.

126. Driving. Any screw-spike *driving tool* should be so arranged as to release when the spike is driven home and thus prevent overdriving. This is commonly arranged by providing a *friction drive.*

127. *Hand driving,* altho inexact, and much more expensiv and time-consuming than machine driving (see ¶¶ 119, etc), must be used where only a few spikes are to be driven, and on very busy tracks (upon which a machine-car cannot be allowd) unless electric or air power can be brought to the tool.

128. For hand-driving, the *simplest* tool is a vert spindle, with a spike socket at its foot, and a hor cross-arm, or ratchet device, at its head.

129. *A crank-driven hand machine, for drilling and driving,* mounted upon an adjustable tripod, and having a hor crank-shaft bevel-geard to the vert spindle, invented by Prof. A. L. Smith, of the Worcester Polytechnic Inst, Worcester, Mass., is described in Bulletin 50, Forestry Bureau, p 53. Under test, this machine drove two screw-spikes while three cut spikes were being driven. It may be operated by power.

130. *Power-driven machines* range from small electric or pneumatic drivers, held by hand, or gasolene motor cars, which the crew can lift from the track, to formidable collections of drills and drivers, installed at the treating plant or mounted upon double-truck cars to save cost of handling ties and to facilitate their removal from the track. They are usually fitted with rail-saws, emery wheels, etc. The larger machines are provided with counters, showing the number of ties handld, and with an exhaust system for the removal of shavings.

131. The Snow gasolene motor car has a gasolene motor, driving a generator which supplies current, thru a cable, to the boring and spiking tools, which may be 1000 ft distant from the car. The car may thus be kept on a side track, out of the way of trains. It weighs, complete, 3400 lbs, and carries ten men besides the driver. It usually avs 2000 to 2500 spikes/day. It can travel 50 miles/hr. Fuses blow out when excessive resistance is encountered, thus protecting the spikes against overdriving. See ¶ 126.

132. The "au-tra-kar", a small gasolene car, can drill a spike hole in an oak tie in from 5 to 10 secs, and drive a spike in about 20 secs.

133. *Speed.* By power, one man can drill 9 holes while 1 is being drild by hand, and can drive 5 screw-spikes while 2 men drive 1 with cross-handld socket-wrench.

134. A *doweling machine,* used by the Santa Fé, had 4 tools; (1) for *boring* dowel holes, (2) for *threading* these holes, (3) for *inserting* the dowels, and (4) for *cutting off* projecting dowel-ends and facing the tie. It could plug the ties for 4000 ft of track per day, while another machine drove the spikes required for the same dist.

A single bit will drill 11,000 holes, 1500 holes betw sharpenings.

The hole should be bored *deeper than the length of the spike*
If bored thru the tie, it will *facilitate the removal of shavings.*

Tie Plates

135. Need. Where the rails bear directly upon the ties, the great unit pressure of the narrow rail base, the churning action of the rail under passing wheels, and the hastening of decay by the bruising of the wood fibers, cause rapid wear of the tie immediately under the rail.

136. Saving. Tie plates greatly lengthen the life of the tie. On curvs and bridges, the saving, in a number of cases, has been estimated at 50% in cost, and 60 to 75% in labor. The tie plate has often displaced small gangs of men whose sole duty it was to replace ties.

137. Types. The tie-plate is placed on the tie, immediately under the rail. Spikes, holding the plate and the rail in place, are driven into the tie thru holes in the plate. Some forms have two or more ribs on the lower side. These ribs stiffen the plate; and,

114a. The design, once adopted, should not be changed, as any change would greatly increase the difficulty of the use of screw-spikes.

115. In order *to protect the spike against bending* under lateral pressure, its head, on each side of the spike, must be well supported, as by properly formd clips, or lugs on the tie-plate, or by fitting the spike-head to the rail-flange.

116. Dowels. Hardwood or metal dowels or plugs, driven or screwd into holes prepared for them, and tapt internally for the screw-spike thread, are advantageously used, especially in softwood ties, either when the spikes are first driven, or after the spike has begun to loosen. If of wood, they are treated before insertion. The large hole, required for the dowel, necessarily weakens the tie somewhat. The dowel acts as a colum, and thus diminishes indentation of the tie. If of wood, the fiber is vert. and, after driving, the top of the dowel is cut off flush with the upper surf of the tie. The dowels are indefinitely renewable during the life of the tie.

117. The Thiollier steel coild spring or helix has been used as a dowel on several Am RRs and in France. Difficulty has been found in placing and in removing the helix.

117a. The Lakhovsky cast-steel split-sleeve, screwd into the tie, and expanding as the spike is driven, has been used in France.

118. Costs. *Screw-spikes* cost from 2 to 3 cents each, or 2 to 3 times as much as cut spikes. *Hardwood dowels,* tapt outside and inside, 1.5 cts each.

119. The costs of the several **operations involvd** vary widely with conditions. Thus, *placing* 2 tie-plates, boring 4 holes and driving 4 screw-spikes, cost 13.74 cts /tie when boring and driving was done *by hand*; 4.89 cts on *scatterd work with a machine* having two drills and one driving tool; and 2.9 cts on *continuous work with machine* having two drills and two driving tools.

120. *Boring.* Mr. J. W. Kendrick, Am Ry Eng & M W Assn, Procs 1910, Vol 11, Part 1, p 625, says:—"A proper machine at the treating plant will bore and plug 600 ties with 8 plugs each, per day of 10 hrs, at a cost of 3.5 cts/tie" = 0.4375 cent/plug; but, in estimating cost/mile, Mr. Kendrick takes "boring ties for, and driving, 24,000 dowels" (8 per tie) at 1 cent each, presumably for field work.

121. Use. Screw-spikes have long been quite generally used on important lines in Europe, and they are now largely used upon a few such lines in the U S, notably upon the Santa Fé and the D L & W.

122. "Ties should be protected against failure from mechanical wear by means of tie-plates and screw-spikes." Report of Committee on Ties. Am Ry Eng Assn, Procs, 1915, Vol 16, p 522.

123. Tie-plates. The use of tie-plates without bottom flanges (see ¶ ¶ 135, etc) is generally considerd essential to satisfactory service with screw-spikes. See ¶ ¶ 115 and 111.

124. The tie-plate is sometimes screw-spiked to the tie, and the rail held by cut-spikes driven thru slots in the tie-plate.

125. Joints. During the first 2 years (1910-11) of its use of screw-spikes, the D L & W used malleable iron joint plates, and the angle bars were slotted for cut-spikes. One screw-spike was used on the outside of the outer angle bar. Later, all joint plates have been rolled, and screw-spikes used in angle bar slots, with one extra screw-spike on outside of the angle bar.

126. Driving. Any screw-spike *driving tool* should be so arranged as to release when the spike is driven home and thus prevent overdriving. This is commonly arranged by providing a *friction drive.*

***For shipment,** plates wired together in bundles of uniform number, weighing $\not>$ 100 lbs. 1915.*

Use.

142. †"Tie plates should be used on all ties in high speed tracks on curvs of 2° or over; on all ties in track subjected to heavy service; on all switch ties, and ties on turntables, ashpits, bridges and trestles; at water stations and track troughs, and thru all road crossings and station platforms. Tie plates should be used on all soft wood ties and on all ties that have been treated."†

‡Unless otherwise directed tie plates will be applied as follows whenever rail or ties are renewed. ("Soft wood" includes all treated or untreated ties except oak);

On new lines: on all soft wood ties in main track;

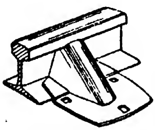
On main lines: on all soft wood ties in main track;

On branch lines; on all soft wood ties on curvs of 3° and sharper, and on all treated ties whether on curv or on tangent;

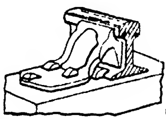
On sidings: on all switch ties and on all curvs of 3° and sharper, and on all treated ties whether on curv or on tangent.‡

Rail Braces

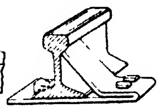
143. Rail braces are used to prevent track spreading, especially on curvs. For 5° curvs, five rail braces per 33-ft rail suffice For 10° curvs, a rail brace is used on each alternate tie.



Alkins Forged-Steel Brace



Ajax Cast-Steel Brace



Edwards Rail Brace and Tie Plate

Fig. 10.

144. Fig 10 shows three types of rail brace in common use.

Joints.

145. The tendency of a track, to yield at the joints, is detrimental both to track and to rolling-stock.

The end of a rail, upon which a loaded wheel is moving, bends more than the adjacent unloaded end of the next rail, which thus receivs a severe blow from the wheel.

146. When the ties are insecurely bedded, no rail-joint can be expected to do good service.

147. Suspended joints (those where the rail-ends meet at a point betw two ties) are generally preferd to supported joints (in which they meet directly over a tie).

148. The expansion coefficient, in steel rails, may be taken at 0.000 006 5 ft/ft/deg Fahr. Hence, a 33 ft rail, (396 ins) under an increase of 60° Fahr in temp, will lengthen by $396 \times 60 \times 0.000\,006\,5 = 0.154$ inch. The rails are also elongated slightly, at their ends, by the traffic passing over them.

*Am Ry Engg Assn. †P R R. ‡U P R R. See also Specifications p 780.

149. Rail creeping (See ¶¶ 163, etc.) brings additional stresses upon the joints. Creeping occurs in the direction of heaviest traffic, and where the traffic is equal in both directions, the creeping is in the direction of down-grade.

150. If, in the two lines of rails forming a track, the joints are placed opposit to each other, they are called **"even joints"**; while **"staggered" or "broken"** joints are those where each joint, in one of the lines of rails, is opp to the middle of a rail in the other line. In the latter and more usual case, the jar of passing from rail to rail is less severe than with even joints, but of course twice as frequent.

151. To lessen this jar, rails have been cut with **beveld or miterd ends**, so that the vert plane, forming the rail-end, makes an angle of 45° to 60° (instead of the usual right angle) with the longitudinal vert plane of the rail web.

152. Angle plates. Figs 7, have practically supplanted all other forms of joint. Their hor flanges give lateral stability to the joint, and carry part of the load directly to the ties, thus relieving the rail-ends to that extent.

153. The slots in the flanges of the angle bar should be so spaced that the two spikes driven into a tie for each rail, shall not be directly opp to each other, but "staggered", in order to reduce the danger of splitting the tie.

154. Usual dimensions, etc, for angle-bar rail joints.

	Angle bars		Bolt holes		Bolts	
rail lbs/yard	length ins	lbs per pair	No	diam ins	length ins	diam ins
70	40	70	6	13/16	4	¾
75	40	76	6	⅞	4⅛	"
85	40	80	6	1 1/16	4½	⅞
90	27	—	4	1	4¼	"

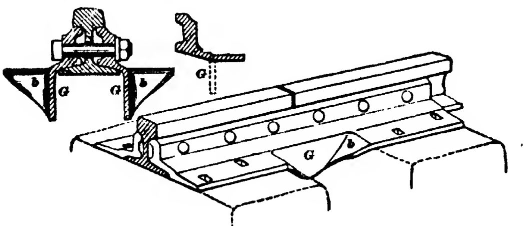


Fig. 11.

155. Bridge Joint. Fig 11. In the bridge joint, the hor flange of the angle bar is rolled wider than usual, and its middle portion is prest downward by dies, forming a girder, *G*, which extends downward betw the two joint-ties. This increases the vert strength of the joint, and the broad flanges increase the bearing surface of the load and increase the lateral strength of the joint; but the downward-projecting flanges (requiring to come between two ties) restrict the liberty of placing the joint with respect to the ties. See end of ¶ 168. Figs 11 represent the Bonzano bridge joint.

Figs. 12.

157. Abbott. In the Abbott rail-joint, invented by F. E. Abbott, Inspecting Engr, Lackawanna Steel Co, the upper edge of each angle-bar is slightly deprest, at center, in order to keep it away from the bottoms of the rail-heads, at the joint, and thus to avoid the wear and cutting of the top of the angle bar by the rail-heads at that point.

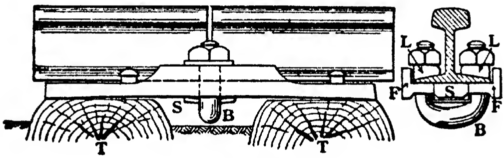

Fig. 13.

158. Fisher. Figs 13. In the Fisher joint (Fisher Rail Joint Works, Trenton, N. J.) the rail *bases*, at their ends, are supported by a flanged plate, *F*, placed under the rail base and bolted to it by a U-bolt, *B*, and clips, *L*, as shown, instead of having the support under the rail *heads* as in the angle-bar joint. A notcht and cambered piece, *S*, of spring steel, placed betw the U-bolt *B*, and the flanged plate, *F*, and held in place by the U-bolt which passes thru the notches, keeps the joint elastic, takes up looseness due to wear, cushions the stresses on the bolt, and maintains pressure betw the threads of bolt and nuts, thus acting as a nut-lock.

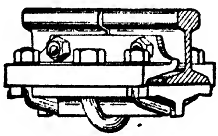

Fig. 14.

159. The "triple fish" (Fisher) joint, Fig 14, has also a supporting plate under the rail-base. It is a short joint, with three U-bolts, as shown, and specially formed angle-bars ("keepers") bolted thru the rail-web

Track Bolts

160. *Unthreaded bolt must bend cold thru 180° and flatten without fracture on outside.*

Threads; U S Standard upset, unless otherwise specified; cut or rolled; $\nless$ 2 $\ngtr$ 5 finger threads.

For shipment, bolts oild; nuts applied for $\nless$ 2 threads. 1915.

Spiral Spring Nut Locks.

Creeping

163. Rail creeping is due to the undulatory motion of the rail under moving trains, and is most markt on roadbeds lacking in firmness, and on heavy grades. The rails creep in the direction in which the trains move; and creeping therefore gives most trouble on double-track lines. It is increast by rail expansion in hot weather, and diminisht by freezing, which restricts the undulatory motion.

164. "Cross-binding", Fig 15, has been successfully used, to prevent creeping. This consists simply in driving the outside spikes, for each rail, as shown, in advance of the inside spikes in

*Am Ry Engg Assn. †P R R. ‡U P R R. See also Specifications p 780.
§For iron tie-plates, see ¶ 140.

that direction in which the rail tends to creep. Then, if, for instance, rail A creeps in the direction indicated by the arrow, carrying its end of the tie with it, the tie is thrown toward the

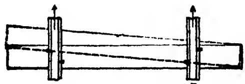

Fig. 15.

position indicated by the dotted lines; increasing (1) the lateral pressures of both its spikes against its flange; (2) the grip of the tie on the rail, and thus (3) the resistce to the sliding of the rail on the tie. And conversely for rail B.

165. Very long ties (sometimes as long as 12 ft) have also been used to reduce or prevent creeping.

166. Slot-spiking of splice-bars is effectiv against creeping, provided the joint-ties hold in the ballast. If they do not, the rails should be anchord to intermediate ties by anti-creeping straps. Or anchors may be made of old splice-bars, cut transversly into sections, leaving one bolt-hole in each section, and making a spike slot in its hor leg. A hole is then drilled in the rail web, over the tie, and the anchor is bolted to the rail, and spiked to the tie thru the slot. Resistance to creeping may then be further increast by fitting blocks betw the ties ahead of the anchord ties.

Another anti-creeping device consists in a clamp which grips the rail base without bolting, and has a lug which bears against the side of a tie.

Altho, in order to prevent rail creeping, the angle splice bars are sometimes slot-spiked to the ties, ¶ 166, it seems preferable to depend upon rail-anchors or anti-creepers; see foregoing ¶ ¶.

167. On the St. Louis bridge (steel arches) and its eastern approach (plate girders on iron columns), the rails crept, in the direction of traffic, about a ft/day, both up and down a grade of 80 ft/mile, and with such force that none of the various fastenings tried sufficed to prevent the creeping, and the track was adjusted daily to accommodate it. See paper by Prof. J. B. Johnson, Assn of Engng Socs, Journal, Vol IV, No 1, Nov 1884.

168. *In relaying rails,* when this involvs changing the positions of the joints, it has been usual to re-space the ties to conform to the new positions; but this practice has been abandoned in some cases, and with apparently beneficial results, the ties and ballast being left undisturbed.

Where angle splice-plates (such as those of the Bonzano joint, ¶ 155) with vert flanges projecting downward betw the ties, are used, tie shifting is of course unavoidable.

Continuous Rails.

169. Expansion and contraction. In street railway work, the rails are commonly **welded, cast or riveted** together at their ends, forming practically continuous rails; and ample experience has shown that, here, as in steam railroad work, a long line of continuous rail does not expand and contract seriously as a whole, under temperature changes; the tendency to expand or contract being successfully resisted by the ground, acting thru the ties and the rail-fastenings. The result is, of course, an increase of longitudinal stress in the rails, with corresponding microscopic changes in their cross-sec areas.

170. Taking the linear expansion coeff, a, of steel, (say 0.000 006 5) as the unit stretch, e, or stretch per unit length, (pp 456-7) under 1° Fahr temp change, and its elastic modulus, E, as 29,000,000 lbs/sq inch, we have unit stress $= E\,e =$ 188.5

lbs/sq inch/deg Fahr. Taking the temp range at 140° Fahr, and assuming the rails laid at mean temp, these would be subjected to a max temp change of 70° and to a max unit stress of 70 × 188.5 = say 13,200 lbs/sq inch, which is well within the allowable unit stress of rail steel.

Miscellaneous

171. Difference, in length, between inner and outer rails. Fig 16.

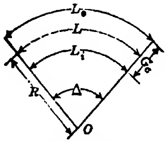

Fig. 16.

Let

R = radius of center line of track;

Δ = sweep of curv,

G_c = gage, measured between *centers* of rails,

L, L_o, L_i = length of arc, on center lines of curv, of outer rail, and of inner rail, respectively.

In a full circle (360°):

$L_o = 2\pi(R + G_c/2) = 2\pi R + 2\pi G_c/2; = 2\pi R + \pi G_c;$

$L_i = 2\pi(R - G_c/2) = 2\pi R - 2\pi G_c/2; = 2\pi R - \pi G_c;$

and, subtracting, $L_o - L_i = 2\pi G_c$.

Hence, in an arc of Δ°, we have:

$$L_o - L_i = 2\pi G_c \frac{\Delta^\circ}{360} = \frac{\pi G_c}{180}\Delta^\circ$$

With gage, G, = 4 ft 8.5 ins, we have G_c = about 4 ft 11 ins = 4.917 ft; and $L_o - L_i$ = 0.085818 Δ°; log 0.085818 = 8.93358.

In any given length, L, on center line, we have

$$\Delta^\circ = 360^\circ \frac{L}{2\pi R} = \frac{180^\circ L}{\pi R}.$$

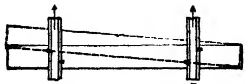
$$\text{Hence } L_o - L_i = \frac{\pi G_c \Delta^\circ}{180} = \frac{\pi G_c}{180}\cdot\frac{180\,L}{\pi R} = \frac{G_c L}{R}.$$

In other words: *for a given sweep*, Δ, the diff, $L_o - L_i$, is *independent of the radius*; whereas, *for an arc of given length*, L, the diff *varies inversely as the radius*, and is *independent of the sweep*.

Gage-widening on Curvs.

172. The necessity and the extent of gage-widening, on curvs, depend upon many variable factors, such as length of rigid wheelbase, the slack, S, or diff betw the track gage, G, (on tangents) and the *wheel* gage, W, (see Fig 2, under "Rolling Stock," p 1040) on both new and worn wheels, etc. Hence, opinions and practice differ widely.

that direction in which the rail tends to creep. Then, if, for instance, rail A creeps in the direction indicated by the arrow, carrying its end of the tie with it, the tie is thrown toward the



A B

Fig. 15.

position indicated by the dotted lines; increasing (1) the lateral pressures of both its spikes against its flange; (2) the grip of the tie on the rail, and thus (3) the resistce to the sliding of the rail on the tie. And conversely for rail B.

165. Very long ties (sometimes as long as 12 ft) have also been used to reduce or prevent creeping.

166. Slot-spiking of splice-bars is effectiv against creeping, provided the joint-ties hold in the ballast. If they do not, the rails should be anchord to intermediate ties by anti-creeping straps. Or anchors may be made of old splice-bars, cut transversly into sections, leaving one bolt-hole in each section, and making a spike slot in its hor leg. A hole is then drilled in the rail web, over the tie, and the anchor is bolted to the rail, and spiked to the tie thru the slot. Resistance to creeping may then be further increast by fitting blocks betw the ties ahead of the anchord ties.

Another anti-creeping device consists in a clamp which grips the rail base without bolting, and has a lug which bears against the side of a tie.

Altho, in order to prevent rail creeping, the angle splice bars are sometimes slot-spiked to the ties, ¶ 166, it seems preferable to depend upon rail-anchors or anti-creepers; see foregoing ¶ ¶.

167. On the St. Louis bridge (steel arches) and its eastern approach (plate girders on iron columns), the rails crept, in the direction of traffic, about a ft/day, both up and down a grade of 80 ft/mile, and with such force that none of the various fastenings tried sufficed to prevent the creeping, and the track was adjusted daily to accommodate it. See paper by Prof. J. B. Johnson, Assn of Engng Socs, Journal, Vol IV, No 1, Nov 1884.

168. *In relaying rails*, when this involvs changing the positions of the joints, it has been usual to re-space the ties to conform to the new positions; but this practice has been abandoned in some cases, and with apparently beneficial results, the ties and ballast being left undisturbed.

Where angle splice-plates (such as those of the Bonzano joint, ¶ 155) with vert flanges projecting downward betw the ties, are used, tie shifting is of course unavoidable.

Continuous Rails.

169. Expansion and contraction. In street railway work, the rails are commonly **welded, cast or riveted** together at their ends, forming practically continuous rails; and ample experience has shown that, here, as in steam railroad work, a long line of continuous rail does not expand and contract seriously as a whole, under temperature changes; the tendency to expand or contract being successfully resisted by the ground, acting thru the ties and the rail-fastenings. The result is, of course, an increase of longitudinal stress in the rails, with corresponding microscopic changes in their cross-sec areas.

170. Taking the linear expansion coeff, a, of steel, (say 0.000 006 5) as the unit stretch, e, or stretch per unit length, (pp 456-7) under 1° Fahr temp change, and its elastic modulus, E, as 29,000,000 lbs/sq inch, we have unit stress $= E\,e =$ 188.5

Then, Fig 18, **for a 4-wheel truck:**

Slack, $S_4 = G_4 - G = m\,n =$ (approx) $m'\,n'$

$= L \sin n'\,E\,m'$

$$= \text{(approx) } L \sin A\,O\,E = L \frac{B + L}{2\,(R_4 + G/2)^*}$$

$$= \frac{L\,(B + L)}{2\,R_4 + G}$$

Approximately enough, $S_4 = \dfrac{L\,B}{2\,R_4} = \dfrac{L\,B\,D}{11{,}460}$.

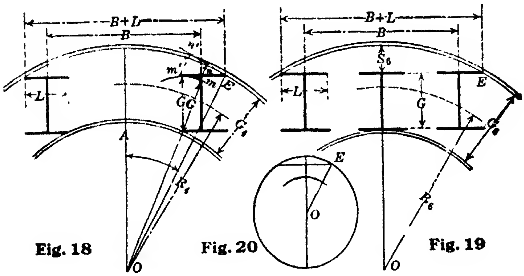


Fig. 18 Fig. 20 Fig. 19

Fig 19. **For a 6-wheel truck;** axles equally spaced, we have, approx (see small-scale Fig 20):

$$S_6 = G_6 - G = \left(\frac{B + L}{2}\right)^2 \times \frac{1}{2\,R_6 + G} = \frac{(B + L)^2}{8\,R_6 + 4\,G^*}$$

Nearly enough, $S_6 = \dfrac{B^2}{8\,R_6} = \dfrac{B^2\,D}{45{,}840}$.

If, in a six-wheel truck, the axles are **unequally spaced,** or **if** there are **more than three axles,** the equation gives S_6 greater than necessary, thus erring on the safe side.

Rail Wear on Curvs.

179. Figs 21. **Special rails** and other devices have been **used,** either to resist or to avoid the lateral forces developt on **curvs,** and the additional wear due to them.

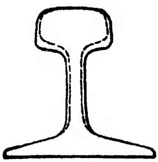

Fig. 21a.

180. Fig 21a. On sharp curvs, the Lehigh Valley RR uses, instead of its normal 100-lb rail, a 110-lb rail, of the same height and base-width, but with a web 1/32 inch thicker, and a head 5/16 inch deeper, with a special outside angle bar, which, on the outer side, projects upward, alongside of the head, to support the head. A special stept or "compromise" joint is used, to effect the transfer betw the normal and the special rail.

---

*As an approximation, G is here used for G_4 or G_6 (still unknown). In practice, G may usually be neglected.

181. Fig 21b. In the **Manning** rail, used on the Balto & Ohio RR, the head thickness is unsymmetrical, the greater thickness being on the side subject to wear. When this has worn down sufficiently, the rail is shifted laterally toward the curv center, in order to take up the wear, and thus restore the gage.

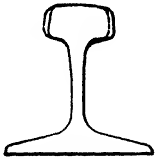

Fig. 21b.

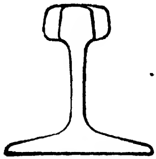

Fig. 21c.

182. Fig 21c. In order to reduce the slip of the inside wheels, in traversing curvs, the Southern Pacific Ry uses, on the inner sides of curvs, a rail with a head 25% narrower than that of the standard rail. The special rail is about 8% deeper than the normal rail A special taper rail is used, to effect the transfer betw the normal and the special rail.

Superelevation. See ¶ ¶ 172 to 193, under "Curvs", p 963.

LAYING AND MAINTENANCE

Laying

183. The complete operation of laying track is usually performed in two stages, (1) Placing the track upon the ground well enough to permit the construction train to run over it, and (2) Ballasting and general completion of work.

184. General. A vital problem of the work is that of transporting ties, rails and fittings from the source of supply to the "front" where they are to be laid. The ties are sometimes carted ahead (part of the distance, at least), on wagons, especially in prairie country, or where a highway lies near by. The rails are usually carried on flat cars in the construction train, which is pusht ahead over the new track as it is laid. The rails, and the ties, when they are carried on the train, must still be transferd from the cars to points just beyond the furthest point of track laid, where they in turn are laid, and spiked and bolted up, sufficiently to permit the construction train to progress over them.

185. Construction Train. The make-up of the construction train will depend upon the speed of laying, dist from base of supplies, grade and motive power, and possible or probable locations of sidings. If the cars used for living purposes are placed at the head of the train, the materials must all be transported around them; and if left on a siding while the work goes on, there may be serious delay in getting them back and forth to the construction crews for meals and sleeping. Frequently they are placed at the front of the train and left there. The order of the cars in the train is usually somewhat as follows, beginning with the car furthest ahead;—

"Pioneer" car; with office, and possibly shop and tools;
Store car, with miscellaneous supplies, for living, etc.;
Bunk and dining car or cars, combined or separate;
Kitchen car;
Additional bunk and dining cars, if necessary;
Tool, or feed and water car;
Rail cars; as many as needed for the day, or as can be handled over the grades and curvs by the motiv power available;

Track fittings car; splice plates, bolts, nuts, etc;
Tie cars; as necessary;
Telegraf line supplies car, (if required);
Fuel car (if the tender capacity is insufficient for a day's service ıd if other sources of supply are not available);
Locomotiv; sometimes several.

186. Forwarding Supplies. At night, or when necessary to reırn for more track material, the bunk and dining cars are left at ıe furthest end of the construction or on a siding, and the loco ›turns with the rail and tie cars (and fuel car, if any) to the base : supplies—probably a yard. Rails and other supplies are there ›aded on to the construction train. Straight and curvd rails, odd-·ngth rails, and hard and soft ties should be loaded separately. therwise, much time may be lost in rehandling and hunting them ıt as needed. By morning, this much of the train returns to the te of operations and connects up with the remainder.

187. The road bed should be well leveld, preparatory to receivıg the ties and rails; as an uneven surface may strain and bend ıe rails badly when the construction train is run over them, or inrease danger of derailment.

188. Piling ties. When ties are stored near the track, the folıwing conditions are usually required., (See also "Seasoning" nder "Ties", ¶ 53, p 788.) *Piled ≮ 10 ft from nearest rail, ft clear betw piles.* †On ground not lower than grade of RR, ıid on foundation of stone or cull ties.† *Piles of either 25 or ‹0 ties.* †Piles ≯ 12 layers high.† *Each pile markt with own-r's name and date when piled* †and number of ties of each kind f wood in pile.† *Sawd and hewd ties piled separately.* †Chest-ıut piled separately.† *Ties treated with zinc-chlorid or other vater solution to be piled in close piles on well-draind ground.*

189. Laying ties. Ties are either deliverd by teams, or are arried ahead by hand, or by the "track-laying machine" (see 199). As far as possible, hardwood ties are reservd for curvs. The ties may be thrown down, and are then laid in place, being ined and spaced by a cord or graduated rod or other means.

190. Laying rails. Rails may be skidded to the ground from he rail car, laterally over a couple of inclined rails; but it is ;enerally regarded as bad practice to let them strike each other, or o let them be thrown on to rough ground. †To be distributed base lown, with uniform bearing surf on roadbed.† They may be car-·ied ahead by men, or dragd by horses, or deliverd by the "track-aying machine" (see ¶ 199), as may appear expedient; and then aid on the ties.

†Rails laid one at a time. Ends brought squarely together ıgainst expansion shims.†

191. Rail-bending for curvs. The necessity for bending rails ›ermanently, before laying them in curvd track, increases with the veight of the rails and with the sharpness of curvature; and lecreases as the rail length increases and as the rail is held ›ecurely to its place under traffic

192. *On curvs of moderate sharpness*, rails are usually laid with-ıut previous bending, being sprung to curv, and then held by the spikes, etc. For curvs sharper than say 10°, and for turnouts, the ·ails are bent at the site, by means of a hand rail-bender, at a ·ost of from $35 to $60 or more, per mile (Camp). For special ayouts, they are sometimes bent (cold) at the mill, by power ma-·hinery.

193. *In turnouts*, the "lead rails should be curvd before they are laid; otherwise it is difficult to prevent them from twisting the headshoes around when attempting to spring a curv into them" (Camp).

LAYING AND MAINTENANCE

Laying

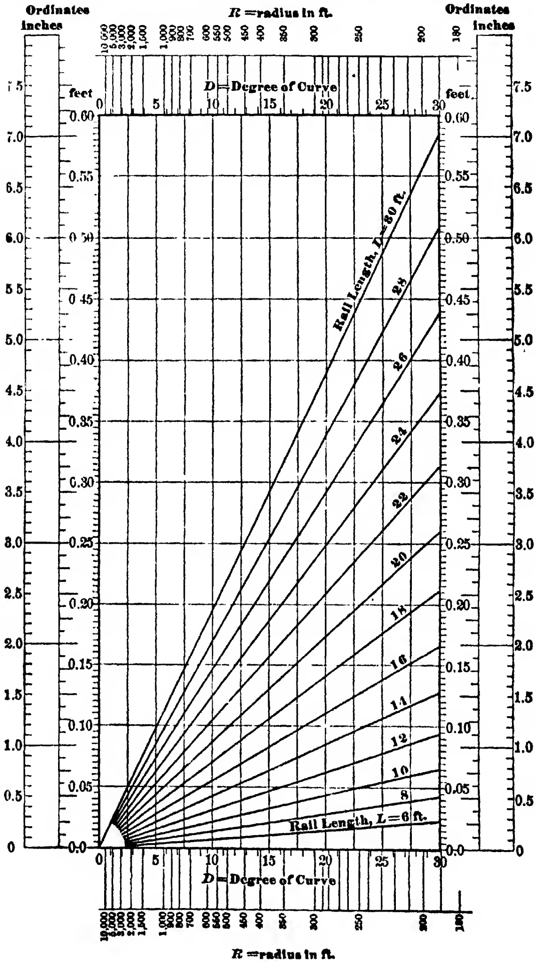
183. The complete operation of laying track is usually performed in two stages, (1) Placing the track upon the ground well enough to permit the construction train to run over it, and (2) Ballasting and general completion of work.

184. General. A vital problem of the work is that of transporting ties, rails and fittings from the source of supply to the "front" where they are to be laid. The ties are sometimes carted ahead (part of the distance, at least), on wagons, especially in prairie country, or where a highway lies near by. The rails are usually carried on flat cars in the construction train, which is pusht ahead over the new track as it is laid. The rails, and the ties, when they are carried on the train, must still be transferd from the cars to points just beyond the furthest point of track laid, where they in turn are laid, and spiked and bolted up, sufficiently to permit the construction train to progress over them.

185. Construction Train. The make-up of the construction train will depend upon the speed of laying, dist from base of supplies, grade and motive power, and possible or probable locations of sidings. If the cars used for living purposes are placed at the head of the train, the materials must all be transported around them; and if left on a siding while the work goes on, there may be serious delay in getting them back and forth to the construction crews for meals and sleeping. Frequently they are placed at the front of the train and left there. The order of the cars in the train is usually somewhat as follows, beginning with the car furthest ahead;—

"Pioneer" car; with office, and possibly shop and tools;
Store car, with miscellaneous supplies, for living, etc.;
Bunk and dining car or cars, combined or separate;
Kitchen car;
Additional bunk and dining cars, if necessary;
Tool, or feed and water car;
Rail cars; as many as needed for the day, or as can be handled over the grades and curvs by the motiv power available;

Middle ordinates for bending rails on curves. See page 816.



194. Expansion and contraction. *Expansion shims* are of many types, from special graduated wedges to wire nails; but they should be of iron or steel, not wood, and should be stampt with the temperatures at which they are to be used. They are placed temporarily betw the rail ends, and so serv to space the rail joints, and thus to provide for expansion and contraction. They are removed later.

195. Provision for expansion. (33 ft rails.) Temperatures, Fahr, taken on rail at time of laying.

Space, in inches betw rail-ends	5/16	1/4	3/16
Am Ry Eng Assn	− 20° to 0°	0° to + 25°	25° to 50°
Penna R R	− 10° to + 14°	14° to 38°	38° to 62°

Space, in inches betw rail-ends	1/8	1/16	0§
Am Ry Eng Assn	50° to 75°	75° to 100°	over 100°
Penna R R	62° to 86°	86° to 110°	over 110°
P R R, in tunnels	22°	46°	over 70°

†At insulating joints, ½ inch, irrespectiv of temp.†

196. Joints are next made up, the splice bars being put in place, some if not all of the bolts past thru the holes, and the nuts tightend up. The expansion shims may then be removed. †*On tangents*, each joint is to be opposit the middle of the opp rail of the same track. *On curvs*, variation $\ngtr$ 18 ins.†

197. Spiking the rails to the ties then follows. The tie is held up against the rail by a man with a "nipping bar", (a lever which straddles the rail and hooks under the tie), and two men drive the spikes, one on each side of the rail, striking alternately Each spike should be driven vertically and should be started with the side of the point squarely in contact with the rail flange, so that it will crowd the rail all the way down Where *screw spikes* are used, the operation is of course different. See under "screw spikes", ¶ ¶ 107 etc. Care is of course taken that the gage be properly establisht when the spikes at the other end of the tie are driven.

198. *Specifications.* †Where tie plates are not used, inside spikes to be driven near east or south edge of tie; outside spikes driven near west or north side of tie; $\nless$ 2 ins from edge of tie. 1909.†

†Spikes per tie at each rail;—

On tangents without tie plate:	1 inside, 1 outside
On tangents with flat or ribd tie plates:	2 inside, 1 outside
On curvs with flat or ribd tie plates;	2 inside, 2 outside.†

Spikes must not be straightend during driving. Outside spikes, of both rails, to be on one side of tie; both inside spikes on the opp side. Spikes ordinarily 2.5 ins from outside of tie. Old spike holes to be plugd.

199. "Track-laying machines", so called, do not actually lay track. They merely facilitate the forwarding of the rails and ties from their cars to the points ahead where wanted. They consist of some form of rollers or track mounted on the construction train, along either one side or both sides, or over the top. In some machines, the run-way is laid on a grade and the material goes ahead by gravity; while in others it is carried on traveling platforms or belts or other transfer devices driven usually by a special stationary engin. Such machines are seldom expected to expedite the work; but only to cheapen it, by reducing the number of laborers necessary.

---

*Am Ry Engg Assn. †P R R. ‡U P R R See also Specifications p 780.
§Laid close, without bumping.

200. Speed of laying, according to Camp, under av conditions; about one mile in 10 hours without hurrying; employing 64 laborers, 3 foremen and 2 teams of horses.

Ballasting.

201. Delivering Ballast. Ordinary flat cars, without sideboards, loaded by steam shovel, hold about 10 cu yds each. With sideboards, 2 ft 8 ins high, a car 40 ft long will hold about 32 cu yds. The sideboards are arranged as a series of doors, hinged at top.

202. Flat cars are economically unloaded by the use of a plow, dragd along the tops of the flat cars, by means of a wire cable, attacht either to the loco, or to an engin drum on a car at end of train. With a loco, the train stands still, and each car deposits its full load within a dist equal to its own length; but, with engin and drum, the distribution of the material can be controlled by having the train in motion.

203. *Center plows* distribute the ballast on both sides of the track. They are guided either by stakes, temporarily placed in the side pockets for the purpose, or by rollers bearing on the sides of the car. The point of the center plow is usually movable sideways; so that, if desired, more ballast may be unloaded on one side of the track than on the other.

204. *Side plows* unload on one side only. They are guided by side stakes Side unloading, with either side or center plows, involves the expense of throwing the ballast back upon the track. See also Dump Cars, under Rolling Stock, ¶ 80, p 1053.

205. To prevent ballast from dropping on the track, betw cars, a hor apron of boiler plate is hinged at one end of each car; so as to overlap the space at the coupling.

206. Leveling. When ballast is unloaded (between the rails) from hopper-bottom dump-cars, it is leveled by means of a spreader plow car, attacht at the rear of the train, or by means of a crosstie fastend ahead of the front wheels of the rear truck of the car being dumpt. Several men, with bars or shovels, are required on the car, to push the material down into the hoppers.

207. Tamping. *Earth or clay ballast.* Shovel equipt with iron cuff or handle for tamping; broad-pointed tamping bars. *Tamp each tie from 18 ins (burnt clay, 15 ins), inside of the rail to end of tie with handle of shovel or tamping bar. If possible, tamp the end of the tie outside of rail first and let train pass over before tamping inside of rail; give special attention to tamping under the rail; tamp center of ties loosely with the blade of the shovel. The dirt or clay betw the ties should be placed in layers and firmly packt with feet or otherwise, so that it will quickly shed the water; the earth should not be bankt above the bottom of the ends of the ties; the filling betw the ties should not touch the rail and should be as high as, or higher than, the top of the ties in the middle of the track. With *broken stone* or *furnace slag*, do not tamp center of ties; bank ballast into shoulder about the end of the ties level with top of tie.*

208. Costs; Ballast, cts per cu yd

Machine-crusht stone, at quarry	45 to 75
Placing under track, and tamping	15 to 25
In track, completely ballasted, lined and drest	75 to 125
Gravel, in completed track	20 to 30
Including, for labor of placing in track, tamping and dressing	10 to 15
Unloading, with plow and cable, including labor of handling cable and use of equipment	0.5
Roadbed oil,	2 to 3½ cts per gallon

*Am Ry Engg Assn. †P R R. ‡U P R R See also Specifications p 780.

209. Oiling Ballast. *On dusty roadbeds,* annoyance to passengers and injury to ties and journals may be prevented by sprinkling the ballast with oil, which penetrates to a depth of several inches, holding down not only the dust already present, but also that which may settle subsequently. It evaporates so slowly that one application per season usually suffices

210. "Roadbed oil" is a product of petroleum distillation, with a spec grav of about 0.89. It is practically non-combustible under the conditions of its use, and it is said that fewer ties are burnd in oild than in unoild track.

211. Oil coating retards the growth of weeds in the ballast; and, by rendering the ballast non-absorbent, reduces heaving of the track by frost. It is believd to preserv ties by excluding moisture.

212. The sprinkling apparatus is commonly installed on a flat car, with couplings for connection to an oil-tank car. In warm weather, the oil flows freely by gravity. In cold weather, its flow may be assisted by steam or air pressure, taken from the loco. The oil is applied to the track, to the shoulder of the roadbed, and, if required, to the slopes in cuts and fills.

213. The sprinkling train can cover about 4 miles/hr, using 2,000 to 2,500 gals of oil per mile of unoild single track Subsequent sprayings require less oil The penetration increases with each spraying, until the depth reaches about 8 ins, which suffices to prevent dry and dusty ballast from being thrown up during tie renewals or tamping.

Maintenance of Way.

214. Surfacing consists of raising depressions in the track, (mostly at joints) to an even surface. It is not necessary to maintain track to the grade stakes to which it was laid when new, as long as it is maintaind fairly even.

215. Surfacing "out of face" (consisting of a resurfacing of the track as a whole) is necessary every few years.

216. *Cost* of surfacing varies from about $100 to $200/mile /annum, depending upon the density of traffic, and upon the materials of which the track is constructed.

217. Ballast. *Renewal.* Before distributing new ballast on the track, the old ballast should be removed from betw the ties as deep as their bottoms, and used to widen the shoulders of the roadbed. See also "Ballasting", ¶ ¶ 201, etc.

218. *Cleaning* ballast. *Intervals, in years, betw cleanings; in terminals, 1 to 3; heavy traffic, coal and coke lines, 3 to 5; light traffic, 5 to 8.*

Under usual conditions, clean only stone and hard slag. Use ballast forks. Clean (a) shoulder, down to sub-grade; (b) betw ties, to bottom of ties; (c) center ditch of double track to subgrade. Return clean ballast.

*Bank gravel (Percentages refer to the *original* bulk)

Road Class	To be Washt or Screend when containing >	Washt or Screend gravel should contain
A	2% dust or 40% sand	≮ 25% ≯ 35% sand
B	3% " or 60% "	≮ 25% ≯ 50% " *

219. Ties. The person inspecting ties, with a view to renewal, may indicate such ties by a spot of white paint. The usual method of putting in new ties is to dig a trench beside the old tie, slightly deeper than the tie; then to pull it sidewise into the trench, and then to haul it out. If the new tie is thicker, or the old tie was rail-cut, it is necessary to dress down the bed of the tie. In rock ballast, ties can be renewed at the rate of 8 or 10/day/man; in gravel, 14 to 18.

---

*Am Ry Engg Assn. †P R R. ‡U P R R. See also Specifications p 780.

220. *Cost of Renewing Ties*

in stone ballast	about 20 cts each
in loose gravel	6 to 10 cts each
in cementing gravel	10 to 20 cts each
in hard slag	9 to 15 cts each

221. Rails. New rails, to be laid, are placed on the ties outside the old rails in place, and bolted together into such sections as can be expeditiously handled. The spikes on the inside of the rail in service are pulled, the rail is lifted out without unbolting the joints (except at ends of sections), and the new rail is set in place and spiked.

222. *On curvs,* rails are often transposed, the worn outside rails being moved to the inside of the track, and the less-worn inside rails to the outside; the inside spikes being pulled, the rails transposed, and the spikes replaced.

223. The hardest track to maintain is that on sharp curvs, elevated for fast passenger trains, and having to carry freight trains whose speed is limited, as by grade conditions.

224. Track-recording cars are of many types, there being apparently no standard. Nearly all carry a long strip of paper, moved by clock-work, or by gearing from the wheels, so that, by means of mechanical pencils or pens, plottings are made, on which the abcissae may represent either time or distance, as desired. In order to identify different portions of the record, it is customary to devote one or two pens to the recording of time by means of a clock sending impulses thru an electro-magnet which actuates a pen; or to recording distance, either automatically, by gearing from the wheels, or by impulses sent from a push-button by an observer watching for mile-posts or other land-marks. These marks are identified, either by making them with certain characteristics, as double, triple, or long marks, or by another operator recording the name by hand, opposit the mark.

225 Various elements are recorded, and in different ways. Lateral or vertical inequalities of the track are recorded either by pendulums, (free, restricted, or "dampt" by "dash-pots"), by the relativ motions of truck and car-body, or by those of an idle wheel or pair of wheels. Some cars are arranged to daub the side of the rail automatically with paint, wherever the track is uneven.

Dynamometer Cars. See under Train Resistance, p 1067. ¶¶ 56, etc.

TURNOUTS AND CROSSINGS

PART I. PRACTICE

TURNOUTS.

For the geometry of turnouts, see Part II, p 848, etc.

General

1. Elements. Figs 1. A turnout consists essentially of a switch, two "lead" rails, L and L_t*, a frog, and two gard-rails, g and g_t.

2. Facing and Trailing. Figs 1. When a train enters a turnout in the direction of the arrow (passing the switch before reaching the frog), it is said to "face" the switch When it approaches (either from the main track, M', or from the turnout, T) in the opposit direction (passing the frog before reaching the switch) it is said to "trail" the switch.

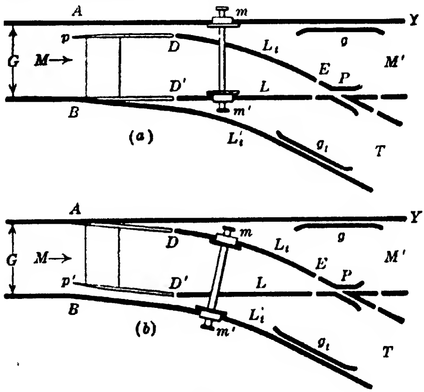


Fig. 1.

3. Double track; Fig 2; trains keeping to the right, as indicated by the arrows. Here, for the normal traffic, X and Y are facing switches; while V and W are trailing switches. In leaving a main track by a trailing switch (*i.e.*, in *facing* a *trailing* switch) a train must move in the direction contrary to the one proper to said track. Nevertheless, the superior safety of trailing switches justifies their use.

4. Fig 2. A turnout is **right-hand** or **left-hand**, accordingly as it sends a *facing* train to the right or to the left from the main track. Thus. V and W are right-hand turnouts, while X and Y are left-hand.

5. The position of the switch (Figs 1), determins which of the two tracks, M' or T, a facing train shall follow. The main lead rail or main closure rail, L, and the turnout lead rail or turnout closure rail, L_t,* lead from the switch to the frog, the flangeways of which permit the flanges of wheels, on either one of the two lead rails, L and L_t,* to pass thru (see pgf 68) the other

*Some writers call the two curvd rails, L_t and L_t', the lead rails. See Webb, Railroad Construction, pp 265 and 272.

lead rail. The two gard-rails, g and g_1, keep said wheels to their proper paths by confining the flanges of their mates while they are passing the frog.

6. The lead (sometimes called the **frog distance**), is the dist, $B\ P$, Figs 1, where P is the theoretical frog-point (¶ 42) and B is the position of the theoretical switch-point (¶ 79) on the turnout side of the main track, $M\ M'$, when the switch is set for the main track, as in Fig 1*a*.

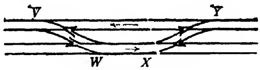

Fig. 2.

7. The lead curv, or turnout curv, $D\ E$, Figs 1, is usually (at least in theory) a simple or circular curv. Fig 13. The gage-lines, $a\ y$ and $b\ z$, of the frog are usually straight thruout the frog, or from frog heel to frog toe; as are also the switch-rails thruout their own length. But see ¶ 77.

Types of Turnouts.

Double Turnouts.

8. Figs 3. In a double turnout (often called a **three-throw or three-way** turnout), two side tracks leav the main track at the same point. As compared with two neighboring turnouts from one track, a double turnout economizes space, material, labor and time, and facilitates operation.

9. Curvature. The *main track* may be *straight or curvd,* and the *side tracks* may leav the main track *on the same or on opp sides.* When they leav from opp sides, their sharpnesses (Curvs, ¶ 11) may be equal or different. Altho, in operation, the side tracks are thus distinguisht, by their *purposes,* from the main track, it is often convenient to disregard this distinction, and to consider the three tracks with regard only to their relativ *positions,* or as *outer* and *middle* tracks. See ¶ 11. Thus, T or T' may be a curvd main track; in which case, M' is a straight turnout.

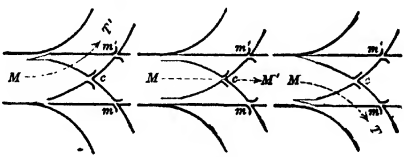

Fig. 3.

10. Elements. Figs 3. A double turnout requires *a 3-throw switch,* two main frogs, m, m', a crotch frog (middle frog), c, and six gard-rails (two for each of the three frogs), unless, as in Figs 3, the two main frog angles (see Part II, ¶ 32) are equal, and the two main frogs therefore opposit; in which case one wing-rail (see ¶ 41) of each main frog acts as gard-rail for the other main frog, and only four gard-rails proper (as shown) are required. When the two main frogs, m and m', are of but slightly diff angles, and therefore nearly opp, it is impracticable to place and maintain the two additional gard-rails of sufficient length. In Figs 3, the two rails of each three-throw switch are indicated by light lines, which show the switch set for tracks T', M' and T, respectivly, as indicated by the arrows. Where the turnout curvature is sharp, the sides of the crotch-frog are sometimes curvd to accord with it.

Main, Side and Connecting Tracks.

11. Of the two tracks, connected by a turnout, it is usually practicable to distinguish betw one, as the *main* track, and the other, as the *side* track. The track, betw the main-track frog and the side-track, is called the connecting track; but the term, "connecting track," is applied also to a track of some length connecting two tracks neither of which is a side track to the other.

12. A spur or stub track is a track (usually short), serving some special purpose, as a neighboring quarry, siding, borrow-pit or warehouse, and not returning to the main track.

12a. A transfer connects two non-adjacent tracks, and the term is used especially when these are at diff levels.

12b. A leader crosses diagonally, and connects, a series of parallel or concentric tracks.

12c. A ladder (see Part II, p 871, § 57) connects a main track with adjacent yard tracks.

Fig. 4a.

Fig. 4b.

Gauntlet and Intervolvd.

13. Fig 4. In certain special cases, as where two parallel or concentric tracks must pass thru a space too narrow for double track, as in a single-track tunnel or bridge, the arrangement shown may be used. Where the traffic, on the two tracks, is in opp directions, the arrangement is called a **gauntlet;** when it is in the same direction, the tracks are said to be **intervolvd.** Two frogs, but no switches, are required. The two tracks are laid upon the same ties.

Fig. 5.

14. Improving Switch Location. Fig 5. To avoid placing a switch on the outside of a curv it may be placed in the tangent, back of the curv-point, *A*, and the traffic carried, on a concentric intervolvd track, to the frog where the turnout, *T*, must leav the main-track curv, *A M'*. This arrangement involvs the use of one switch and one frog.

15. An arrangement of intervolvd tracks is sometimes used for the **protection of track scales** from unnecessary usage by traffic which is not to be weighd. The track, carrying such traffic, rests upon solid piers passing thru, but independent of, the scale platform. This arrangement involvs the use of two switches, without a frog. See Yards and Stations, § 60.

Diamond or equilateral turnout.

16. Where a parallel or concentric side track leavs a straight or curvd main track, the main track ordinarily continues its course unaffected by the presence of the turnout; the deflection, from this course, being effected entirely in the turnout.

17. If, however, the defl be equally divided betw the main and the side tracks, we have a "diamond" or "equilateral" turnout. This permits the use of a frog of greater angle (lower number), without sharpening the curvature. See Part II, ¶ 52.

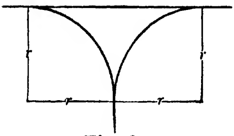

Fig. 6.

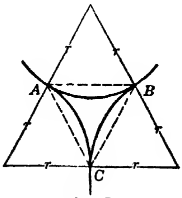

Fig. 7.

Y-Tracks.

18. A Y-track, Figs 6 & 7, is used for turning engins end for end. It thus takes the place of a turntable. Entire trains, if not too long, may be turnd on the Y, as well. The Y should cost less, for maintenance, than a turntable; and may cost less to install, depending upon the cost of ground.

19. Fig 7. Other things equal, the *Y occupies least ground when* the three tracks, or "legs," are curvs of equal radius, *r*, and of equal length. The three switches are then at the apices of an equilateral triangle, *A B C*, each side of which equals the common radius, *r*.

Derailing.

20. General. Cars, left on sidings, may be moved, by gravity, wind, carelessness, etc., to positions near enough to the main track to endanger main-track traffic by collision. Cars may start, by gravity alone, upon a down grade of about 0.4 per cent (21 ft per mile); or (under wind) on flatter grades or on level track. It is unsafe to depend upon the brakes.

21. Usually a dist of 12 ft betw track centers (say 6.5 to 7 ft clear betw rail-heads) is considered safe. The Penna R R, 1909, requires $\not<$ 16 ft from cen of siding to cen of main track, (18 ft where practicable), except on passing sidings where parallel to main tracks; the unconnected end of siding, adjacent to main track, to be curvd outward.

22. The point, where the two tracks approach closer than allowable, is often indicated by a **clearance post** of wood or of metal. If set betw the tracks, such posts are dangerous to men at night. They are therefore preferably placed 4 or 5 ft to one side of either track. Sometimes the clearance point is indicated by a whitewasht half-round tie, laid across the space betw the tracks.

23. A derail is used in main or in side tracks where derailing is preferable to allowing a car to reach a danger-point, such as a switch or a crossing, etc.

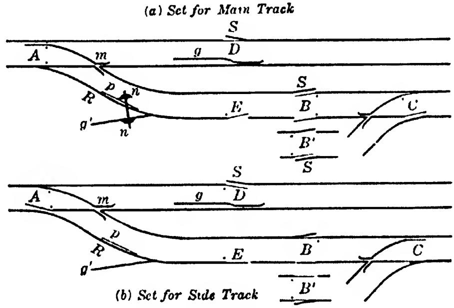
24. Figs 8*a*, 8*b*. *The heel ends* of the switch-rails are indicated by small dots on inside of track.

25. *A single derailing switch-rail*, as at *D* or *E*, suffices for mere derailment; but a *pair of switch-rails*, as at *B*, facilitates restoring derailed cars to the track. In the derailing position, the switch-rail is usually supported by two or three rail-braces. See Track, ¶ 143.

26. The derailing switches are preferably so *connected with the main-track switch*, *A*, that the derails shall always be in the positions proper to the position of the main-track switch. (Compare Figs 8*a* and 8*b*.) Otherwise, a sign, reminding the switchman to set the derail, may be placed at the main-track switch.

27. In main-track derails, as at *D*, the stock-rail, *S*, is bent outward; and a single derailing switch-rail is commonly used, heeling toward the main track frog, *m*, and opening inward, Fig 8*b*.

28. In side track, a single derailing switch-rail, *E*, placed in the outer rail, heels toward the main-track frog, *m*, and opens inward, as in Fig 8*a*.



Figs. 8.

29. Fig 8*a*. Where a car, deraild from the turnout, as at *E*, might nevertheless foul the main track (as *where the derail is near the main-line switch*, and the side-track grade is considerable), a long gard-rail, *g'*, may be used, to keep the farther wheels, *n*, away from the main track, and a plank, *p*, to carry the nearer wheels, *n'*, over the adjacent side-track rail, *R*. Or a derailing *turnout*, *C*, may be used.

30. Fig 8*b*. A main-track car, deraild at *D*, is kept near its proper course by a long gard-rail, *g*, placed about 8 ins from that rail which is opposit the derailing switch. This gard-rail may be continued backward, and bent, as shown, narrowing the flangeway opposit the derail, and thus *protecting the derail switch-point* when the derail switch is set for the main line, as in Fig 8*a*.

31. Figs 8*a*, 8*b*. **In double track,** if a single derailing switch-rail, *D* or *E*, is used, it is usually placed in an *outer* rail, in order to avoid obstruction of the other track by deraild cars.

32. Direction of Heeling. Figs 8*a*, 8*b*. Where a pair of derailing switches, *B* or *B'*, is used in the side track, they may either, as at *B*, heel *away* from the main-track frog, *m*, opening *away from* the main track; or, as at *B'*, they may heel *toward* the main-track frog and open *toward* the main track; in either case guiding a deraild car *away* from the main track.

33. Wharton Switch. A special short form of Wharton switch (see ¶¶ 119, etc.) is used for main-track derails, the derailing switch rails being thrown *against* the main track rails for *derailing*, and *away* from them for *main-track* traffic. This arrangement leavs the main track unbroken; and its wide throw avoids danger of fouling the derail when set for main line.

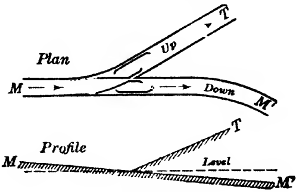


Fig. 9.

Catch Sidings.

34. Fig 9. Catch-sidings are often provided for the purpose of diverting and holding run-away cars on steep down grades, especially when approaching curvs. The catch-siding runs a short dist up the hillside; and the switch is held, by a spring, in position for the siding, as shown; so that the run-away car is diverted to the siding, and there first brought to rest by its own weight. It then runs back, by gravity, to and thru the switch, and up the main-track grade. It thus oscillates, coming finally to rest at the switch. In normal operation, the switch is thrown over to the main-track position, against the spring, by the switchman, who holds it there until the car or train has passed the switch.

For Scotch-block, see Signals, ¶ 47, p 989.

Crossovers.

35. Figs 10*a*, 10*b*. A crossover connects two parallel or concentric tracks. It consists of two turnouts (facing in opp directions) and a connecting track, which may be a tangent or a reverse curv.

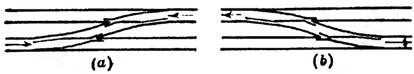

Fig. 10.

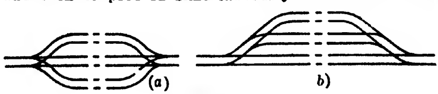
36. Right and Left. With right-hand traffic (as in **Figs 10*a*** and 10*b*), the two turnouts are both *left*-hand, if *facing*, as in Fig 10*a*; and both *right*-hand, if *trailing*, as in Fig 10*b*.

37. Double Siding. Figs 11*a*, 11*b*. On single track lines, in order to allow two meeting trains to await the passage of a third train, and then to proceed simultaneously and without backing or



Figs. 11.

interference, a double siding is provided. The side tracks may be one on each side of the main track, Fig 11*a*, or both on the same side, Fig 11*b*.

38. The lap siding, Fig 12, has the advantage that the telegraph office may be placed at the lap, and therefore convenient to the engins of both standing trains, thus facilitating operation. As will be seen, the lap siding is, in effect, a double track, of length *A B*, with a crossover midway of its length.

Fig. 12.

Gage.

39. Some roads maintain standard gage on turnouts. Others widen the gage by from ¼ to ½ inch, betw switch-point and frog-heel, beyond which points the gage is gradually narrowd to standard width within a dist of about 30 ft each way; while, on European roads, the gage is often narrowd ¼" in the turnout, in order to prevent lateral play of the wheels, and to steady vehicles while on the turnout. The Wharton switch, see ¶¶ 119, etc., requires, at the switch, a gage ½" wider than standard.

Frogs.

Rigid or Stiff Frog.

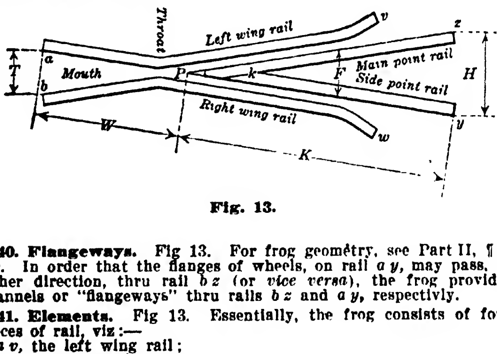


Fig. 13.

40. Flangeways. Fig 13. For frog geomêtry, see Part II, ¶ 2, etc. In order that the flanges of wheels, on rail *a y*, may pass, in either direction, thru rail *b z* (or *vice versa*), the frog provides channels or "flangeways" thru rails *b z* and *a y*, respectivly.

41. Elements. Fig 13. Essentially, the frog consists of four pieces of rail, viz:—

a v, the left wing rail;
b w, the right wing rail;
P z, the main point or long point;
k y, the side point or short point.

42. The gage lines, thru the frog, are *a y* and *b z*. Fig 13. To the *remaining parts and dimensions* of the frog are given names as follows:—

Toe spread, *T*, = *a b*, measured betw gage lines at rail heads;
Heel spread, *H*, = *z y*; measured betw gage lines at rail heads:
Throat, the point of shortest distance between wing rails;
Mouth, the trapezoidal space betw the two wing rails and betw throat and toe;
Theoretical frog point, *P*; the intersection of the gage lines, *a y* and *b z*;
Actual (or "half inch") frog point;

Tongue, the triangle betw P and k;
Flangeways or channels, the two parallel-sided channels betw the points and the wings;
Frog angle, F, $= z\,P\,y = a\,P\,b$.

43. The frog number, N, is the quotient, l/i, where l (not shown) = the length of any portion of the frog, and i (not shown) = the increase of frog width (measd betw gage-lines and perp to the frog axis) within that portion. l is measd, by some engineers, along the center-line of the frog; and, by others, along a gage-line; and the number of a given frog is of course correspondingly affected. See Part II, ¶ 6 etc.

44. Right and left. Fig 13. The *side* point, $k\,y$, is ordinarily placed in the *turnout*. Hence, a frog is called "*right*-hand" if a person, facing it, sees the *side* point on the *right*, and *vice versa*.

45. Fillers. The two point-rails are riveted together, and a steel filler is secured in place betw the point and each wing-rail. The two fillers are sometimes carried beyond the point, and joined there, forming a single straddling filler.

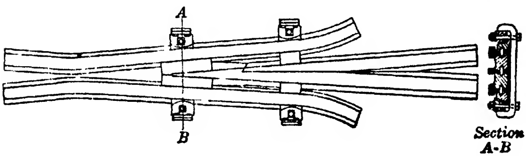

Fig. 14a.

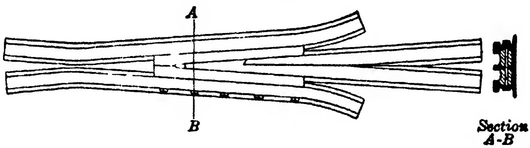

Fig. 14b.

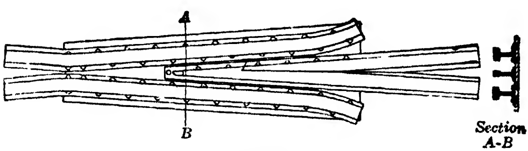

Fig. 14c.

46. Fastenings. The wing-rails and the point, are held together, in their proper relativ positions, usually either
(1) by clamps and keys, Fig 14*a*;
(2) by bolts, Fig 14*b*;
(3) by riveting to a plate, Fig 14*c*;
(4) by bolts and plate [combination of (2) and (3)]; or
(5) by riveting to tie plates.

47. Practice, respecting the choice betw these methods, is indicated by the results of two canvases, showing the number of roads using each method, as follows:—

	(1) Clampt	(2) Bolted	(3) Plate	(4) Bolt and plate	Total
Roadmasters' Assn, 1897,	7	29	9	....	45
Eng News, 1908 Jun 4,	7	32	15	10	64

Frogs are connected with the adjoining track rails by the usual rail joints. See Track, ¶¶ 145, etc.

48. Altho one side of the frog is in the turnout curv, and the other side may be in a main-line curv, yet the shortness of the sides warrants making them straight, except in very sharp turnouts and in special cases.

49. Length. The frog length must be such that the rail ends, at toe and at heel, are far enough apart to give room for the rail-joints without interference. Increast length strengthens the frog against working loose; but it also increases waste when frogs must be renewd, because the adjoining rails always outwear the frogs. The adoption of a standard frog reduces the rail cutting required when frogs are renewd. See ¶ 70.

50. Details. The wing-rail on the turnout side is sometimes made slightly longer, at the toe, than the other wing-rail, in order that the main and turnout lead rails (¶ 5) may be of equal length, and still bring the heels of the switch rails opposit.

Wear, Reinforcement, etc.

51. Special Steel. Those parts of frogs which are subjected to heavy wear are frequently made from special manganese or other steel of high wearing quality, and built into the body of the frog. Frogs so made cost about twice as much as do ordinary frogs; but their use is nevertheless economical under heavy traffic.

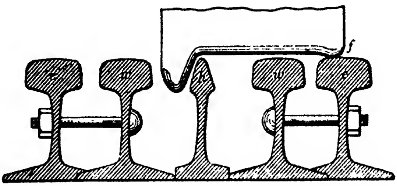

Fig. 15.

52. Easer Rails. Fig 15. False or outside wheel flanges, *f*, are formd by the wearing down of the tread, nearer to the flange. A short easer rail, *e*, bolted outside of each wing rail, *w*, and forming, with *w*, a double-headed wing, raises the wheel sufficiently to keep the worn tread out of contact with the point-rail, *h*.

53. Heel Block or Heel Raiser. Figs 16. The false flange, *f*, of a trailing wheel, dropping betw the point-rails, *M* and *S*, tends to wedge them apart. To prevent this, a heel block or heel raiser, *R*, is bolted in place betw the point rails. The raiser slopes downward toward the frog heel, as shown, in order to lift and lower the wheels gradually. It may be a solid steel casting, or an inverted piece of rail. It also servs as a foot gard. See ¶ 75. Unless securely fastend, it may be driven forward by the false flange, *f*, and may thus itself act as a destructiv wedge

*54. In the rigid or stiff frog (thus far described) all the parts are immovable, and both flangeways are always open. The wing-rails, Fig 13, by supporting the outer portion of the wheel-tread, protect the relativly slender frog-point, which otherwise would receiv hard usage from passing wheels; and the flangeways are made as narrow as possible, in order to diminish the severity of the blows deliverd by wheels passing them; but, nevertheless, these blows become serious under heavy traffic.

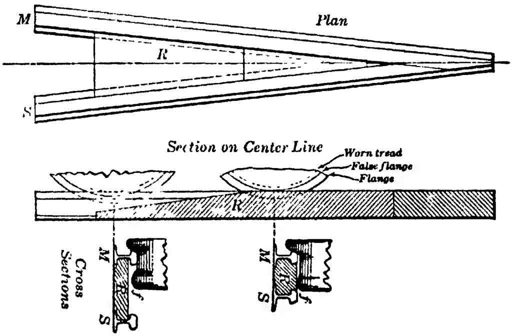

Fig. 16.

55. High Flangeways. In early days, in order to obviate this difficulty, the flangeways were made shallow, so that the wheels, traversing them, ran upon their flanges, their treads being thus lifted above contact with the rail-heads; but the flanges soon cut grooves, which lowerd the wheels until the treads again bore upon the rail-heads, striking blows as before.

Spring-rail Frogs.

56. Action. Figs 17, 18. In the spring-rail frog, the turnout wing-rail, *b s w* (called the spring-rail), altho spliced to the track rail at its toe, *b*, is spiked along only its *gage* side, and it may therefore be moved away from contact with the point, *P y*, against which it is normally held by springs, as at *h*. Any main-track wheel, *m'* (like its mate, *m*) has thus always a full bearing thru the frog. The spring-rail slides on large fixt plates, which extend under all the frog rails.

Of 59 railroads interrogated, 58 used spring-rail frogs as standard. Eng News, 1908 June 4.

57. Wheels, *n'*, *o'*, passing to or from the *turnout*, thru the frog, must cross the flangeway betw the point-rail, *P z*, and the wing-rail, *P v*. To obtain flangeway, betw the spring-rail, *s w*, and the point, *P y*, the flange of a *trailing* wheel, *o'*, merely pushes in betw the two; while a *facing* wheel, *n* (being held away from the frog by the gard-rail, *gt*), necessarily guides its mate wheel, *n'*, in that direction also, and thus forces the spring-rail, *s w*, away from the point, *P y*, and opens a flangeway for wheel *n'*. In either case, the spring, *h*, restores the spring-rail, *s w*, to its normal position, in contact with the point, *P y*, after the passage of each wheel.

58. Guide-box. Figs 17, 18. In order to prevent the free end, *w*, of the spring-rail, *b w*, from rising, when a load is concentrated at or near its other end, *b*, there is fastend, to the web of the spring-rail, near *w*, a forging, the horizontal tongue of which slides in a guide-box, *c*, riveted to a fixt slide-plate extending under all the frog rails at that point. The guide-box acts also as a stop, to prevent the free end, *w*, of the spring-rail, from moving out too far.

59. In order that the spring-rail head may fit snugly against the point-rail head, its *flange must be cut away* on the side next to the point. The spring-rail, thus weakend, is *reinforced*, usually by a strap riveted or bolted to its web.

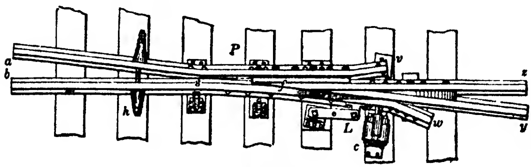

Fig. 17.

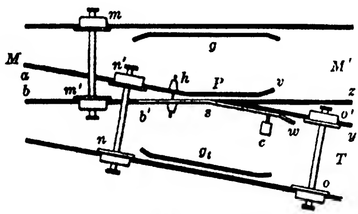

Fig. 18.

60. Provision against false flanges. Fig 18. If the bearing, betw the head of the spring-rail, *s w*, and that of the point-rail, *P y*, is too short, a false flange (¶ 52) worn on the outer edge of the tread of a trailing main-line wheel, *m'*, passing from *M'* toward *M*, may strike the spring-rail flare, *w*, and thus wedge the spring-rail away from the point, *P*. To prevent this, the spring-rail, *s w*, is given a longer bearing against the point-rail, *P y*, than would otherwise be necessary. For a similar reason, the spring-rail head, where in contact with the frog-point, is planed down to a groove parallel with the main-track gage-line, as indicated by the shading in Fig 17, providing a flangeway for false flanges.

61. For Main Track only. Since ordinary spring-rail frogs present a full bearing to the treads of only *main*-track wheels, *m'*, Fig 18, and not to those of turnout wheels, *n'* and *o'*, they are most useful where most of the traffic uses the main track, and where but few trains use the turnout. But see ¶¶ 66, 67.

62. Right and Left. Rigid frogs (except those with unequal wing-rails, ¶ 50) may be used for right-hand or for left-hand turnouts interchangeably; but spring-rail frogs must be made either right-hand or left-hand.

63. Creeping. Fig 17. To prevent the spring-rail from creeping, without restricting its lateral motion, the link, *L*, is used. The link is so set that the tendency to creep shall force the spring-rail *against* the tongue, and not *away* from it.

64. *In the hinged spring-rail frog* (designd to avoid the necessity of providing against creeping of the spring-rail) the latter is divided at *s*, Fig 17; and the portion *b s* is fixt in position, while the portion, *s w*, is hinged at *w*, instead of at *s*, where it is left free to swing outward against a spring, which restores it to its place in contact with the point, after the passage of each wheel.

65. On Curvs. Figs 17, 18. When a spring-rail frog is used on the outside of a main-track curv, the centrif force of a main-track train, pushing against the spring-rail, between *b* and *s*, tends to open it This tendency is resisted only by the gard-rail, *g*, Fig 18, opposit, but it is relievd by slightly flaring the spring-rail away from contact with the tongue near the point.

66. Double Spring-rail Frog. In the double spring-rail frog, both wing-rails are equipt as spring-rails, and each moves independently of the other. Both flangeways are closed when no wheels are passing. Such frogs are adapted to turnouts where the traffic, on main line and on turnout, is about equal. See ¶ 61.

67. Slid'ng Wing-rail Frog. In the sliding wing-rail frog, the two wing-rails are rigidly connected, at a fixt dist apart; but are free to slide together, so that either of them may rest against the fixt tongue, leaving a flangeway between the other wing-rail and the tongue. Wheels, either facing or trailing, open the flangeway (if it is not already open) by sliding the wing-rails over (facing wheels effecting this by means of the opp gard-rail). The wings then remain in the new position for following wheels. The wing-rails must slide, under high friction, while one of them carries the load of the first wheel; and an obstruction, lodged betw one wing-rail and the tongue, may hold the wing-rails fast, and cause derailment. Like the double-spring-rail frog, ¶ 66, the sliding wing-rail frog is designed for cases where the traffic, on main line and on turnout, is nearly equal. See ¶ 61.

Continuous Main Rail Frogs.

68. In order to leav the main rail always unbroken, certain frogs so elevate the turnout rail that wheel flanges on the turnout pass *over* (insted of thru) the main rail, the treads being carried by short supporting rails, which are swung temporarily into position, meeting over the main rail for this purpose, and which are afterward swung aside, in opposit directions, from the main rail, in clearing the main line. The switch is set simultaneously with the frog.

Specifications, Use, etc.

69. Requirements. In ordering frogs, specify type and details of construction; section and wt of rail; frog number or angle; length over all; length from half-inch point to heel; spacing of rail-joint holes at heel and at toe; thickness and dimensions of plate used; and, in the case of a spring-rail frog, or other frog with unequal wings at toe, whether right-hand or left-hand. In order that the parts may be interchangeable, specify also that all frogs of one kind shall be made alike as to drilling of bolt and rivet holes. Wing rails (which wear out much faster than point-rails) can then be readily replaced.

70. Dimensions, Am Ry Engng Assn, Manual, 1915, pp 168-170. **Sizes or Numbers.** (See also end of this paragraph for other than A R E A.) "Nos. 8, 11 and 16 frogs are recommended as meeting all general requirements for yards, main track switches and junctions. New work should be laid out, as far as practicable, for these three frogs, so as to effect the gradual elimination of frogs of other numbers, lessen the cost of manufacture, and decrease the amount of stock carried."

Rigid Frogs. Figs 13

Frog No.	*W*	*K*	*W + K*	*T*	*H*
8	4′ 9″	8′ 9″	13′ 6″	7 1/16″	13 1/8″
11	6′ 0″	11′ 6″	17′ 6″	6 [illegible]/16″	12 9/16″
16	8′ 0″	16′ 0″	24′ 0″	6″	12″

See also ¶ 71.

Diams of bolts for all the foregoing rigid and spring frogs

Rail,	100-lb	90-lb	80-lb	70-lb	60-lb
Diam, ins,	1⅛	1⅛	1⅛	1	⅞

For spring-rail frogs, Fig 17.

Ends of wing rails chamferd at 45° with vertical

No 11 spring frog has five ⅝ inch open-end prest-steel stop-blocks.

Sizes or Nos. *For main-track slow-speed* turnouts, Nos 8 or 9 to 12 frogs are commonly used; *for high speed,* as at ends of double track, Nos 15 or 16 to 20. *In yards,* Nos 6 or 7 to 8 or 9 are used; in crowded *industrial yards,* for locomotivs of short wheel-base, Nos 4 to 6.

71. Flangeways. A canvass of 59 railroads showed that 38 used flangeways, in frogs and for gard-rails, 1¾″ wide; 18 used 1⅞″, and 3 used 2 ins.

Gard-Rails.

72. Fig 1. In passing thru the frog, each wheel is held to its proper course by the gard-rail, *g, g₁,* acting upon its mate wheel.

73. Details. On the side next the track rail, the gard-rail flange is cut away (or the gard-rail is rolled with its web inclined toward the track rail) in order to allow room for spiking, in the narrow flangeway. Instead of rails, thus trimmed or distorted, heavy steel angles have been used as gard-rails. The standard flangeway width extends for one or two feet each way from a point opp the frog point. The gard-rail ends are preferably planed down to a long bevel, to avoid their being caught by accidentally trailing objects; or the web, near the end, may be removed, and the head bent down to the desired slope. In main track, the gard-rails are from 15 to 18 ft long.

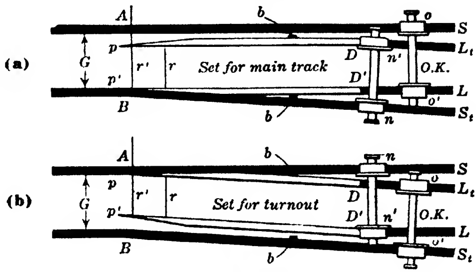
74. Fastenings. The gard-rails (sometimes weakened by the removal of one flange, ¶ 73) have to withstand severe lateral pressures; and they are therefore supported, usually by rail-braces, secured to the ties on the side opp to the track rail. Or tie-plates, extending under both the gard-rail and the main rail, may be used: or the gard-rail may be bolted to the track rail, and separated from it by filler-blocks, which, near the flaring ends, act also as foot-gards. See ¶ 75.

75. Foot Gards. Where the clear space, between adjacent rails, is betw 2½ and 5 ins, there is danger that men may have their feet caught and held in front of an advancing train. Such points are found at the ends of gard-rails, at the throat and heel of frogs, in the flare of wing rails, and in switches. Foot-gards are intended to prevent such accidents. They are required by law in some states. They are formd of pieces of plank, cut to fit the spaces and spiked to the ties; or of properly shaped wooden or cast iron blocks or steel strips, bolted to the rail webs; or of steel bars, bent into a series of angles, and placed on edge

Switches.

The Point Switch.

For the stub switch, see ¶¶ 96-99.
For the Wharton switch, see ¶¶ 119-126.



Figs. 19.

76. General. Figs 19*a* and 19*b* represent, in outline, the principle of the point or split switch, now in practically universal use on main lines. For simplicity, the rail flanges are omitted from the Figs, and only the rail heads are shown. In each Fig, the switch is shown set for the wheels marked "O. K." It is misplaced for the others. The lead-rails, L_t and L (see ¶ 1, Fig 1), and the stock-rails, S and S_t, are permanently spiked to the ties. S is the main stock-rail (or thru rail), and S_t is the turnout stock-rail (or knee-rail). At B, the knee-rail, S_t, is bent to a sharp angle = switch angle, s (Fig 21), and sometimes kinkt there, for the reception of the toe of the point-rail, $p' D'$, when set for the main track, as in Fig 19*a*.

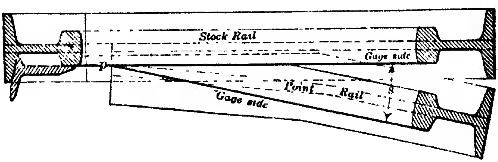


Fig. 20.

77. The switch or point rails, $p\ D$, $p'\ D'$, **Figs 19, are formd from ordinary track rails, so planed, Fig 20 (for the taper at the point), as to leav the gage side straight; and they are left straight (except for very sharp turnouts, where they are sometimes curvd). They remain straight while being set for the turnout; swinging about their heels,** D, D', **Figs 19.**

78. Length of Point. In ordinary turnouts, on lines where 30 or 33-ft rails are used in the main track, the switch-rail length (for economy in rail-cutting) is usually 15 ft or 16′ 6″, or half a rail-length; for high speeds, however, as at end of double track, switch-lengths of 20 to 30 ft are used; for yards and branches, 10 or

11 ft. In any case, the switch length must be at least such that the rail joints, at the heels, *D* and *D'*, Figs 19, shall not crowd the stock-rails.

See table, Part 2, ¶ 47

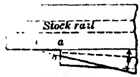

Fig. 21.

79. The Switch Angle is the angle, *s*, Figs 20, 21, between the gage sides of the switch-rail and stock-rail. On account of the thickness, *a b*, Fig 21, of the actual point or toe, the theoretical switch-point, or the vertex, *v*, of this angle is at a distance, = *v a*. from said actual point. (See table of split switches, ¶ 94.) Actual switch-point thickness, *a b*, = *v a* tan *s*.

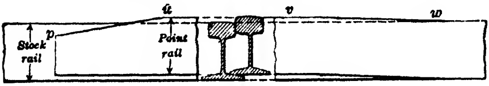

Fig. 22.

80. Details of Design. Fig 22. To protect the thin portion of each switch-rail, near the toe, the top of that portion is planed down to about ½ inch below the top of the adjacent stock-rail, at *p*; but, from *p*, the switch-rail top rises uniformly, in a varying distance, *p u* (see table ¶ 94), until, at *u*, the top of the switch-rail is about ¼ inch *higher* than that of the adjacent stock-rail, in order that the "false flange" of a gutterd wheel, Fig 23, may not foul the stock-rail, or wedge the two rails apart by dropping into the narrow space between them. From *u*, Fig 22, the top of the switch-rail maintains this superelevation for several feet, as to *v*, and then declines until the tops of the two rails are at the same level, as at *w*. Sometimes (for the same purpose) instead of thus *raising the switch-rail*, at *u*, the *stock*-rail is planed *down* to bring its top below that of the switch-rail.

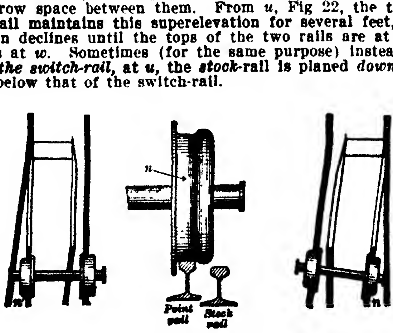

Fig. 23.

81. Protection and Reinforcement. To avoid danger of striking the open points, the *throw*, at *p*, Fig 19*a*; *p'*, Fig 19*b*, is made greater than would be necessary for merely passing the wheel flanges. The Am Ry Engng Assn, (see ¶ 94, below) specifies 5 ins.

82. Except in yards and for slow traffic, the *point-rails* are reinforced, at least thruout the planed portion, usually by a pair of strap pieces, from ¼ to ⅝ inch thick, and wide enough to fill the space betw head and flange, riveted or bolted one on each side of the rail web. An angle-bar or a channel-bar is sometimes substituted for one of the strap pieces.

83. In the *"channel" switch,* a piece of light T-rail, of proper length, is bolted alongside of the point-rail, from which it is held about 6" dist by two or three separators, placed at intervals. The resulting rigidity tends to prevent wrongly locking the switch when an accidental obstruction separates the two rails which should be brought together. See ¶ 48, under Signals, p 989.

84. Figs 19. *Stop-blocks, b,* or stop-lugs, are short metal blocks, bolted to the web of either the point-rail (Fig 19*a*) or the stock-rail (Fig 19*b*) at suitable intervals, at points where the two rails themselvs never come into contact. Their thickness is such as to afford a bearing betw either point-rail and the adjacent stock-rail, when these are at their nearest. They thus brace the point-rail against the stock-rail, enabling it better to resist the lateral pressure of passing wheels, which (owing to centrifugal force) is especially heavy on curvs. Usually, one, two or three such blocks are placed on each side of each switch.

85. **Steel Slide Plates,** 5 to 6 ins wide, and spiked to the ties, extend under both the switch-rail and the stock-rail, betw toe of switch and the point where the flanges of the switch-rail and the stock-rail separate. There are usually 6 to 8 such plates on each side of the switch. They serv the double purpose of guiding the switch-rail to its seat on the base of the stock-rail, and (by means of a raisd seat on which the switch-rail rests and slides) of elevating the switch-rail above the stock-rail, as mentioned in ¶ 80. They are generally made to receiv *rail-braces* to reinforce the stock-rail on the outside.

86. **Gage Plate.** In place of the two slide-plates, next to the toe, a single long plate, extending entirely across the track, and called a gage-plate, is sometimes used. It acts not only as a slide-plate, but also to hold the stock-rails to gage, by means of lugs attached to it.

87. **Tie Rods, Switch Rods, Tie Bars, Bridle Rods.** Figs 19. The two point-rails are connected, as indicated, by means of tie rods (switch rods, tie bars, bridle rods), *r, r',* fastend preferably to the webs of the point-rails, usually by hinged connections, to facilitate the change of angle involvd in the throwing of the switch.

88. The tie rods are sometimes made *adjustable in length,* in order to correct for wear and for accidental shifting of one or of both switch-rails.

89. *Number used* On main lines, the tie rods are usually from 2 to 5 in number. Their presence interferes with tamping; but when few rods are used, additional reinforcement of the switch-rails becomes necessary.

90. *Location.* The tie rods are placed below the levels of the tie tops, to avoid their being hit by wheels of cars, or dragd by parts of the rolling stock which may accidentally become partially detacht.

91. *Cross-section.* In point switches, the tie rods are usually flat, and are placed either vertically edgewise (in which position they resist canting of the point rails), or horizontally.

92. Figs 19. The tie rod, *r',* nearest to the toe is called the *head rod,* or *No 1* rod. At each end, it extends under the stock-rail, in order to prevent the toe end of the switch from rising out of place. At one of its ends it is jointed to the connecting rod (usually 1 to 1¼ ins round or square) leading to the switch stand.

93. Specifications Required. In ordering point switches specify gage of track; switch-rail length; switch throw, measd at head rod; rail section; drilling for rail joints; switch angle; and heel spread.

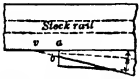

Fig. 21. (Repeated.)

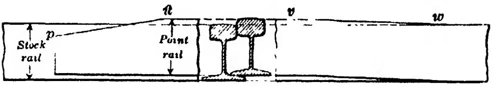

Fig. 22. (Repeated.)

94. Switch specification, Am Ry Engng Assn, Manual, 1915, pp 178-9.

Switch throw, 5 ins at center line of No 1 rod, *r'*, Figs 19.

Heel spread, at *D* and at *D'*, Figs 19, 6.25 ins betw gage lines of stock-rail and switch-rail.

Frog number, *N*			Switch length $l = pD$	*p u*	*v a*
Limitations		Recommended	Figs 19	Fig 22	Fig 21
≯ 6		. . .	11 ft 0 ins	5 ft	5.50 ins
> 6	≯ 10	8	16 ft 6 ins	7 ft	8.25 ins
> 10	≯ 14	11	22 ft 0 ins	9 ft	11.00 ins
> 14		16	33 ft 0 ins	12 ft	16.50 ins

Reinforcing bars, ⅝" thick; height to fill space betw head and flange; length as great as heel connections permit.

Two non-adjustable switch-rods, ¾" × 2½"; placed horizontally; 20" apart, cen to cen. Cen of head-rod 12" back from switch-toe.

On each tie, *two slide-plates,* ⅝" × 7", planed down to receiv stock-rail and braces.

95. A three-throw switch, Fig 3, consists virtually of two separate point switches; and, in fact, these are sometimes so arranged, the points of the two pairs of switch-rails being placed about a switch-rail length apart, or in "tandem"

Stub Switches.

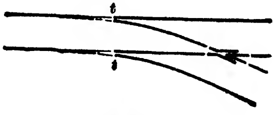

Fig. 24.

96. Fig 24. The stub switch (still used in subordinate locations, as in turnouts from branch lines) is simple in construction, and cheap in first cost, but expensiv in operation and maintenance. To avoid possibility of binding in hot weather, a considerable space must be left betw the toes, *t t*, and the ends of the adjacent track rails, and this subjects the rail-ends to serious blows from passing wheels. Such blows are injurious both to the rail-ends and to rolling-stock.

97. Danger. A lateral shifting, of either the toe or the adjacent rail-end, relativly to the other, causes a shoulder, called "lip", which may become very dangerous. But the most serious objection to the unprotected stub switch is the inevitable derailment of trailing cars when the switch is wrongly set.

98. Length. Stub-switch rails are usually full-length track rails, 30 or 33 ft long. Of this length, 4 or 5 ft, next to the heels, are spiked to the ties, leaving the remainder free to spring to a curv when thrown for the turnout.

99. The throw, or dist thru which the toes move, must be at least equal to the rail-head width (usually 2 to 2.5 ins) plus a width (1.75 to 2.5 ins) sufficient to pass the wheel flanges. Usually the throw is made from 5 to 5.5 ins

Switch Stands.

100. The lever, by means of which (thru the connecting rod) the switch is thrown, is housed in a "stand." The arrangements vary greatly. The lever may rotate in a vert or in a hor plane. If in a vert plane, this plane may be either perp to, or parallel with, the track; the movement of the lever, in the latter case, being transmitted to the connecting rod by means of gearing or a bell crank.

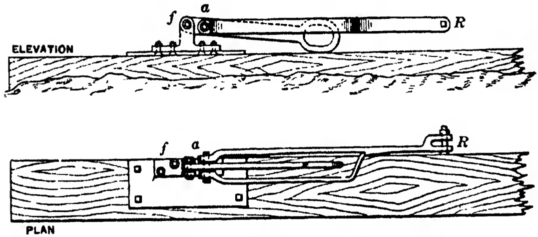

Fig. 25.

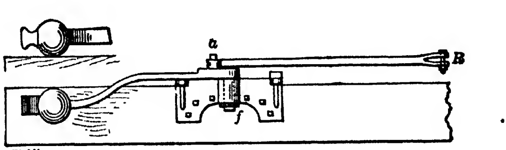

Fig. 26.

101. Ground or Tumbling Lever. Figs 25 and 26 show the "ground lever" or "tumbling lever" stand. In Fig 25, the lever moves thru an arc of a little more than 180°, in a vert plane, either perp to, or parallel with, the track; so that, when the lever is at rest, its joint, *a*, with the connecting rod, is a little below the fulcrum, *f*, about which the lever itself revolvs, or below dead center; so that the switch cannot be thrown by the lateral pressure of wheels pushing thru it. In Fig 26, the free end of the lever is weighted, and the joint, *a*, when the lever is at rest, is *above* dead center. This permits the automatic throwing of a misplaced switch by trailing wheels. See ¶ 57.

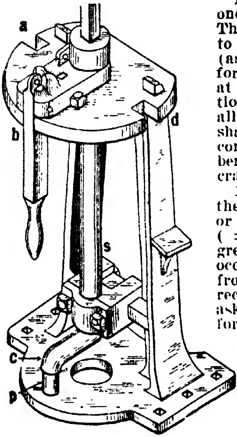

Fig. 27.

102. Revolving Stand. Fig 27 shows one of many forms of revolving stand. The lever is usually hinged, so as to hang vertically, and out of the way (as shown), when not actually in use for throwing the switch. The notches, at *a*, *b* and *d*, hold it in its three positions, respectivly. The crank, *c*, is usually formd, as shown, by bending the shaft, *s*; and the pin, *p*, to which the connecting rod is attacht, is formd by bending (up or down) the end of the crank.

103. Fig 28*a*. If, in a revolving stand, the crank-pin is moved 90° from *a* to *b*, or *vice versa*, the lateral movement (= $a' b'$ = $b' a'$) of the switch-rail, is greater than that (= $b' c'$) which occurs when the crank-pin is moved 90° from *b* to *c*, or *vice versa*. This may be rectified by setting the stand slightly askew, as indicated by the dotted lines; for this shifts b' materially toward a', while a' and c' are but very slightly shifted. Or, Fig 28*b*, the stand may be so set that the line *o d*, normal to the switch-rod, bisects the 90° throw of the crank, but this arrangement does not bring the crank to dead center in either position. For a given switch-rail throw, and given crank-throw angle, Fig 28*a* requires a longer crank than does Fig 28*b*.

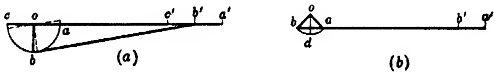

Fig. 28.

104. Locks. To prevent tampering with the switch, the lever is usually provided with a padlock and staples: but stands with self-containd and more elaborate locks have been used. See also end of ¶ 58, Signals, pp 990 and 991.

105. A target, at the top of a vertical shaft and operated simultaneously with the switch, indicates how the switch is set. The target may be a single disc, showing the switch-setting by its position (edgwise or flatwise to an approaching train); or it may have two discs, set at right angles, and differing in shape, in color or in both. See also Signals, ¶ 14, p 984.

106. Low, Pony, Intermediate or High Stands are those in which the top of the target is ≯ 2 ft, 2 to 4 ft, 6 to 8 ft, or about 18 ft, above ground, respectivly. Intermediate stands are in general use; low and pony stands are used betw neighboring tracks, and high stands where the target of a lower stand would be hidden by intervening objects.

107. Lamps. For switches which are to be used at night, the stand carries also a lamp, showing colors corresponding to those used on the target See Signals, p 984. Kerosene lamps are in general use; but, in large yards, incandescent electric lights are often used.

Automatic Switches.

108. Automatic switches are those in which the connections with the stand are such as to permit the passage of a trailing car when the switch is wrongly set for it.

109. Figs 19*a*, 19*b*. The flange of a trailing wheel, *n*, on the stock-rail, crowding into the narrowing space betw it and the adjacent switch-rail, will (if not prevented) throw the latter over, away from the stock-rail, thus providing, for wheel *n*, a flangeway betw those two rails; the other switch-rail being simultaneously thrown over against the opposit stock-rail, or into proper position for the mate wheel, *n'*.

110. A "set-over" automatic switch is one in which the point-rails, when automatically thrown, as in ¶ 109, carry over the switch lever, and remain in the new position.

111. In the "fly-back" automatic switch, the switch lever is not thrown when a trailing car passes a mis-set switch. The switch-rails are only temporarily pusht aside, and, after the passage of each pair of wheels, are returnd to their former positions by means of a spring in the head-rod connection, in the connecting rod, or in the stand. The stand throw is made a little greater than the switch throw, in order to take up lost motion.

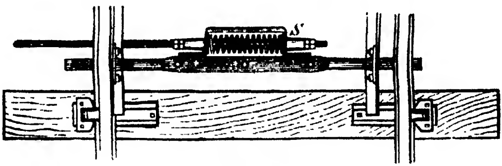

Fig. 29.

112. Objections. Both forms are open to the objection that the throwing of the switch takes place while part of the moving load is bearing upon one of the relativly slender switch-rails, which must therefore slide while loaded.

113. Lorenz spring. Fig 29 shows, in principle, the Lorenz spring, much used in "fly-back" automatic switches. The spring, *S*, is sometimes placed outside of the track.

114. The *repeated blows* of the switch-rails against the stock-rails in automatic switches are injurious, especially to the slender switch-rails; and permanent compression of the spring, resulting from long service, may leave a switch-rail (after the lever is thrown) improperly out of contact with its stock-rail, endangering facing wheels.

115. *The spring* also may permit the lever to be forced home, even when ice, a small stone, or other obstruction, lodged betw a switch-rail and a stock-rail, prevents complete setting of the switch.

116. Automatic & Non-Automatic. Frequently the rod, passing thru the coil spring, is provided with two adjustable sleevs, by means of which the switch may be arranged, at pleasure, in either one of several ways. According to this arrangement (*a*, *b*, *c*, etc), a trailing car, coming to a misplaced switch may pass it freely if coming either

(*a*) from the main line;

(*b*) from the turnout;

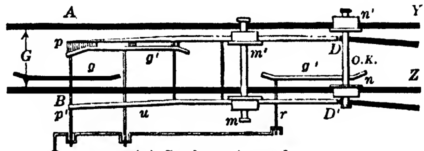
(*c*) from either the main line or the turnout;

or the sleevs may be so adjusted as to prevent the spring from acting; the switch thus being renderd non-automatic, so that a trailing car, whether coming from the main line or from the turnout, cannot freely pass the switch if the latter is misplaced.

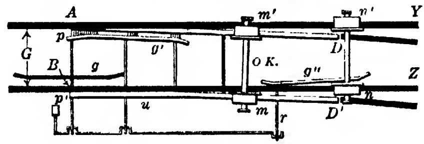
117. The *use of automatic and of non-automatic* ("rigid") switch stands, compared as follows:—

In 1900, 24 roads used automatic, and 23 roads used rigid stands; in 1908, 23 roads used automatic, and 29 roads used rigid stands Eng News, 1908 June 4.

118. Specifications Required. In ordering switch-stands, specify switch throw at point of connection, size of head rod and whether vert or hor, diam of hole in head rod, length and diam of connecting rod, style of target and its height above the ties, and dimension of lantern tip on shaft.



(*a*) *Set for main track*



(*b*) *Set for turnout*

Figs. 30.

Wharton Switch.

119. Figs 30*a* and *b*. We omit the rail flanges, showing only the rail heads. *Moving* rails are shown *white*. Wheels, for which the switch is properly set, are markt "O. K." Fig 30*a* shows the switch set for the main line; Fig 30*b* shows it set for the turnout.

120. *A Y* and *B Z* are the main-track rails. They are continuous (except, of course, that *B Z* is broken at the *frog*, beyond the Fig), and are spiked to the ties thruout. They are not moved or broken in the working of the switch. *p D* and *p' D'* are the switch-rails.

121. The Switch-rail, *p' D'* (the "elevated rail"), is blunt-ended. At its toe, *p'*, its top is level with that of *B Z*; but, at *u*, 4 or 5 ft back from the toe, its top is about 2" higher than that of *B Z*. This enables the flange of wheel *m*, in passing to or from the turnout, Fig 30*b*, to clear the main rail, *B Z*. *p' D'* retains this elevation from *u* to its heel, *D'*. Beyond *D'*, the turnout rail, continuous with *p' D'*, slopes downward until its top is at the normal level. The **"point-rail,"** *p D*, is elevated also, to prevent the lateral rocking of rolling stock which would otherwise result from the elevation of *p' D'*.

122. The reinforcing or "point" gard-rail, *g'*, is bolted to, and separated from, the point-rail, *p D*, and moves with it. Flange-way is left betw their heads. In Fig 30*b*, by confining the flange of wheel *m'*, *g'* holds the flange of wheel *m* clear of the head of rail *B Z*, in coming down the incline, *u p'*.

123. In Fig 30*b* the point, *p*, fits close against the head of the main rail, *A Y*; so that the flange of wheel *m'*, moving in either direction, clears the point, *p*; and the fixt gard-rail, *g*, confining the flange of *m*, holds *m'* away from *A Y*, thus affording additional protection to the point, *p*.

124. Early patterns were provided with special attachments, designed to receiv, from the turnout, a trailing car when the switch was set for the main line, and to guide it safely on to the main track; but this device has been abandoned, on the ground that its cost and complication are not warranted by the probability, under proper management, of such misplacement.

125. Trailing. Fig 30*b*. If a trailing car moves along the main track while the switch is set for the turnout, the flange of its first wheel, *n*, pushes aside *g''* (compare Fig 30*a*) which, pulling the rod, *r*, throws the switch into the proper position for the main track, as in Fig 30*a*.

126. Gage. For proper working of the Wharton switch, the main-track gage, at the switch, is made half-inch wider than the standard gage.

Computations.

127. Many of the approximations, permissible in computing turnouts of small angle, such as are usual on steam lines, are inadmissible in street railway turnouts and crossings, where the layouts are frequently very complex. Hence, the design of such work is preferably entrusted to mfrs who specialize in it.

Ties.

128. Turnout Ties, for standard gage, vary, in length, betw that of an ordinary tie (say 8.5 ft) and 24 ft. One or two ties, 12 to 16 ft long according to the style of switch stand, are used at the toes of split and of stub switches as a seat for the stand, and are called **Head-Blocks.** The set of ties should extend, beyond the frog, to a point where the ends of the ties of the two tracks do not interfere. Ties 7 × 9 ins are commonly used, except under the frog, where 7 × 10 ins ties are used, to give greater bearing area, and strength to resist the shocks of wheels passing over the frog. They are generally orderd in lengths varying by 6 ins. For ties in general, see under Track, p 784, etc.

Switch Ties.

129. Digest of Am Ry Engng Assn Specifications. Manual 1915, following p 176.

All 7" × 9".

Lengths for 8' 6" track-ties. For 8' 0" track-ties, the switch-tie lengths are in general 6 ins less than here given.

Length, ins	180*	108	114	120	126	132	138	144	150	156
	Number of switch-ties, beginning at switch-point									
Frog No 8,	2	8	7	5	4	3	3	3	3	3
Frog No 11,	2	12	10	8	5	5	5	3	3	4
Frog No 16,	2	20	14	10	9	6	6	5	5	5

(Table concluded)

Length, ins	162	168	174	180	186	192	198	Total	
	Number of switch-ties								
Frog No 8,	2	3	2	3	2	3	2	58 ties,	3651 ft B M
Frog No 11,	4	3	3	2	3	3	3	78 "	4814 ft "
Frog No 16,	5	5	4	5	5	4	5	115 "	7111 ft "

*Each turnout has two head-blocks, 7" × 9", 15 ft long.

130. Tie Spacing, for turnouts. Beginning at switch-point. Center to center. For use with 8′ 6″ track-ties. Ties 7″ × 9″.

										Total
Frog No 8	Number of ties,	5	4	18	3	7	9	6	5	57
	Space, ins	20	21	20	19	20	18	19	20	
	Total, ins	100	84	360	57	140	162	114	100	93′ 1″

	Total, ins	342	380	76	320	76	400	285	360	186′ 7″

Timber Bills.

The following are typical timber bills for double (three-way) turnouts and for crossovers.

131. For Double Turnouts. Two headblocks 7″ × 10″, 16′ long. Ties under frogs spaced 23″. Other ties spaced 24″.

Length, ins.	108	114	120	126	132	138	144	150	156	162
	Number of ties, beginning at switch point									
Frog No 6,	5	4	3	2	2	1	1	1	2*	1*
Frog No 8,	5	4	4	2	3	2	1	2	1*	1*
Frog No 10,	5	4	4	3	3	2	2	2	2*	1*

(Table continued)

Length, ins.	168	174	180	186	192	198	204	216	222	228
	Number of ties, beginning at switch point.									
Frog No 6,	1*	0	1	1	1	1	1*	1*	1*	1*
Frog No 8,	2*	1	1	1	2	1	1*	2*	0	2*
Frog No 10,	1*	2	2	2	2	0	2*	2*	0	2*

(Table concluded)

Length, ins.	240	252	264	270	276	288	Total	Ft B M
	Number of ties, beginning at switch point							
Frog No 6,	1	2	1	0	2	1	38	3069
Frog No 8,	2*	2	2	0	1	2	47	3828
Frog No 10,	3	2	2	2	2	3	57	4754

132. For Crossovers. (13 ft cens). Four headblocks 7″ × 10″, 16′ long. Ties under frogs spaced 23″. Other ties spaced 24″.

Length, ins.	102	108	114	120	126	132	138
	Number of ties, beginning at switch point.						
Frog No 6,	8	8	6	6	6	4	4
Frog No 8,	10	8	8	6	6	6	6
Frog No 10,	10	10	10	8	8	8	8

(Table concluded)

Length, ins.	144	150	156	258	258	Total	Ft B M
	Number of ties, beginning at switch point.						
Frog No 6,	4	2	4*	4*	6	62	4392
Frog No 8,	6	6	4*	4*	9	79	5544
Frog No 10,	6	6	6*	6*	11	97	6817

*Frog ties, 7″ × 10″. Other ties, 7″ × 9″.

Laying.

133. Time required. When not greatly interrupted by passing rains, "a good foreman and six fair trackmen can put in either stub- or a split-switch turnout in one day of ten hrs, including he removal of old track ties and putting in switch ties." Camp, lotes on Track, p 298.

Miscellaneous.

134. To prevent creeping of the point-rails, dependence is usully placed upon slot-spiking the four rail-joints at the ends of the rog, those at the two point-rail heels, and the intermediate joints n the lead-rails. Anchoring the switchpoint rails, at their heels, o the neighboring stock-rails, has given trouble by crowding the oints out of line.

Removal of Ice and Snow.

135. Steam Heating. Where numerous switches are in proxmity, they may be economically kept clear of ice and snow by steam pipes, fed from some central source, and laid betw several pairs of switch ties, near the point, the ballast being first removed. The pipes are provided with automatic traps, which allow the conlenst steam to escape, and thus prevent its freezing in the pipes. See Ry Age Gaz, 1910 May 13, p 1199.

136. Burning Fluid. Turnouts have been cheaply and expeditiously cleard (and kept clear) of ice and snow, by means of a fluid hydrocarbon (a by-product of the Pintsch gas plant), applied, where needed, by means of a safety distributing can, and ignited. The fluid burns, in spite of wind and snow, melting, and finally evaporating, the snow. The flame temperature is not sufficient to injure the rails. The fluid costs from 3 to 5 cts per gallon. Where several neighboring switches are to be servd, the liquid is stored in tanks, and distributed, by gravity or by comprest air, thru piping.

See Engineering-Contracting, 1908, Sep 2, p 151.

137. To protect switch rods from becoming bent or broken in cases of derailment, a sawd tie may be placed each side of each rod, leaving 2.5" clear space, betw ties, for the rod. In cold weather, bent rods should be heated before it is attempted to straighten them. Ballast should be kept clear of the rods, and well draind in their vicinity, especially in cold weather.

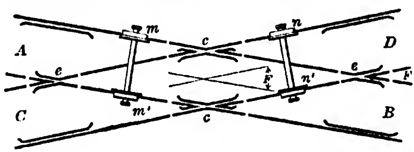

Fig. 31.

CROSSINGS

138. Fig 31. A crossing consists essentially of four frogs, *e*, *e*, *c* and *c*, and the necessary gard-rails.

139. The crossing angle, or end-frog angle, is the angle, *F*, betw center lines of the two straight crossing tracks.

140. Where F = 90°, the four frogs are all alike. In Fig 31 the two sharp "end" frogs, *e*, are alike, and similar to turnout frogs. The two blunt "middle" frogs, *c*, are alike also. The presence of the gard rails, at the middle frogs, gives the appearance of a second point, opposite the point, *c*, proper; and the middle frogs are therefore often called "double-pointed", altho the inside "points", formed by the angles in the gard-rails, carry no wheels.

141. Where one or both tracks are curvd, the frogs all have different angles; and are curvd thruout. Crossings of curvd tracks are best avoided. Problems concerning them are conveniently solvd by means of large-scale plottings.

142. Double-rail Crossing. Fig 31. If the middle gard-rails are extended, both ways, until they meet opposit the end frogs, and are properly filled, bolted and connected, the strength and durability of the crossing are greatly increast, and it is called a "double-rail" crossing. In this case, the end frogs, *e*, (as well as the middle frogs, *c*), are "double-pointed" (¶ 140).

143. An easer rail (¶ 52), to carry "false-flanges", is sometimes bolted outside the running rail.

144. When F exceeds say 35°, the webs of both of the main, gard and easer-rails of one of the two tracks, sometimes run thru the crossing uncut; the flangeways, for wheels on the other track, being cut thru the heads only of these rails.

145. When F is betw 15° and 40°, the four frogs usually meet directly; but in small-angle crossings, to avoid handling long frogs, pieces of rail are laid betw the ends of the frog rails, as in Fig 31. For convenience in shipping and handling, crossings are made with as few field joints as possible.

146. When F is less than say 10°, Fig 31, the middle frog points are nearly opp each other on either one of the two tracks, and cannot be properly garded. Thus, wheels *m* and *m'* might leav their proper track, *A B*, at the middle frogs, and take track *C D;* or wheels *n* and *n'* might leav track *D C*, and take track *B A*.

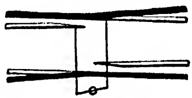

Fig. 32.

In such cases (Fig 32) the middle gard-rails are dispenst with, and a **"movable point center frog",** consisting of two pairs of short point switch-rails, facing each other, is used. These switches are, as required, seated against one of the two bent stock-rails, as shown. They may be operated by an automatic switch-stand, so that, if a train approaches a wrongly set crossing, the forward wheels force open the trailing switch-rails, and automatically throw the facing switch-rails into proper position.

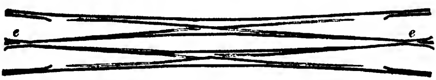

Fig. 33.

147. Slip-Switch or Combination Crossing. Fig 33. At a small-angle crossing, traffic may be intentionally diverted from one track to another by means of a slip-switch or "combination crossing", consisting of an arrangement of switch and connecting rails in addition to a regular crossing, all placed betw the two end frogs, *e*. Fig 33 shows a double slip-switch. In a single slip-switch, the switches and connecting rails are provided on one side only.

148. The slip-switch is especially useful for connecting a *leader* (see ¶ 12*b*) with the parallel tracks which it crosses. Such a combination saves much room, lengthwise, and givs a straight line, as compared with a series of separate crossovers.

149. *Movable-point center-frogs* may be used, as in Fig 33, in slip-switches; but *ordinary rigid middle frogs* are used instead, both with single and with double slip-switches, except where the angle is so small that the wings of the frogs interfere with the curvd rails connecting the switch-rails.

150. *Switch levers.* These crossings may be operated by an ordinary switch-stand for each pair of switch-rails and one for the movable-point center-frogs, if such are used; or all the switches may be connected by a system of rods and cranks, and operated from a single stand, while the movable point-frogs are operated from another stand. Or the switch-points and movable frog-points may be so arranged that they operate together.

151. Continuous Rail Crossings. In crossings of very large angle, the wheels, in crossing the flangeways, drop into them, delivering severe blows to rolling stock and to track; and devices have been constructed which afford continuous rails at such crossings, by means of a short section of rail, or its equivalent, which, thru an interlocking system, can be placed temporarily in line with the rail to be used.

152. Ties. Crossing ties, extending under both tracks, are usually laid at right angles to the long diagonal of the diamond formed by the crossing rails; sometimes at right angles with the line carrying the heavier traffic; and sometimes ordinary-length ties are used, at right angles with each track. For ties, see ¶ 128.

153. Specifications Required. In ordering crossings, specify type of construction; crossing angle, *F*, Fig 31; track gage; distance, cen to cen, betw parallel tracks, if there is more than one; rail section; lengths of arms of frogs; and bolt-hole spacing required in ends of arms to suit rail joints in use.

TURNOUTS AND CROSSINGS

PART II. THEORY

Geometry of Turnouts.

For Construction of Turnouts, see Part I, p 822.

1. Accuracy. Scrupulous accuracy is not necessary in the measurements of turnouts. A deviation of several per cent, in length of lead or of turnout radius, from the theoretical value, will seldom be noticeable. The traind eye of an expert trackman, or a large-scale drawing, may secure as good results as careful calculation. Nevertheless, the engineer should be informd as to the broader features of the geometry of turnouts. We therefore give, below, equations (both exact and approximate) covering the simpler cases.

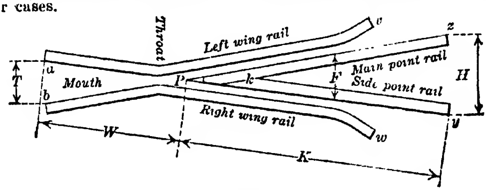

Fig. 1.

Frog angle and frog number.

For description of frog, see Part I, ¶ 40, etc.

2. Frog Angle. Figs 1 and 2. The theoretical frog point, P, is the intersection of the two gage-lines bounding the frog-tongue. The frog angle, F, is the angle, at the theoretical frog-point, betw the two gage-lines.

3. *How determind.* Figs 1 and 2. The frog angle, F, depends upon the sharpness-difference (¶ 29) betw the turnout curv and the main-line curv (if any) and upon the track-gage.

4. *How exprest.* Fig 2. The frog angle is usually exprest by means of the ratio, k/i, betw the length, k (not shown), of any portion of the frog, and the increase, i (not shown), of the frog width within that portion. This is also the ratio betw any given portion, (m or s, beginning at P, see below) of the frog length, and the corresponding spread, h. This ratio is called the frog number, N.

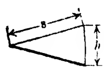
5. Frog Number. *N is determind* in two diff ways, viz:—

$$N = \frac{m}{h} = \frac{\cot(F/2)}{2}$$

$$2N = \cot(F/2)$$

$$N = \frac{s}{h} = \frac{1}{2\sin(F/2)}$$

$$2N = \operatorname{cosec}(F/2)$$



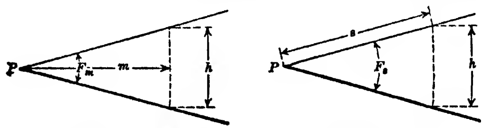
Eq (1)

6. The *Am Ry Engng Assn* makes $N = m/h = \frac{1}{2}\cot(F/2)$, as in Fig 2*a* (see values of F, in table, Manual, 1915, p 184); but railroad companies and mfrs are divided as to their practice in this

respect; many preferring the second formula, $N = s/h$, Fig 2b, because the frog length is customarily and more satisfactorily measd along a gage-line, s, than along the center line, m. Moreover, the length, so measd, is usually in even figures of ft and ins; and hence the spread is easily found by mentally dividing said length by the frog number.

7. Comparison of frog angles, F_m and F_s

N	F_m $\cot(F_m/2) = 2N$ Fig 2a	F_s $\operatorname{cosec}(F_s/2) = 2N$ Fig 2b	$F_s - F_m$ seconds	$\dfrac{F_m}{F_s - F_m}$
4	14° 15′ 00″	14° 21′ 41″	401	128
8	7° 9′ 10″	7° 10′ 00″	50	515
11	5° 12′ 18″	5° 12′ 38″	20	937
16	3° 34′ 47″	3° 34′ 54″	7	1841
24	2° 23′ 13″	2° 23′ 15″	1.87	4606



For $h=1$, $N=m$ (a)　　For $h=1$, $N=s$ (b)

Fig. 2.

8. Functions of the frog angle, F, in terms of the frog number, N.

See p 97b, ¶ 16, and p 97c, ¶ 19.

Fig 2a	Fig 2b
	Taking $N = \dfrac{m}{h} = \dfrac{1}{2}\cot(F/2)$ we have $\tan(F/2) = \dfrac{1}{2N}$, and	Taking $N = \dfrac{s}{h} = \dfrac{1}{2\sin(F/2)}$ we have $\sin^2(F/2) = \dfrac{1}{4N^2}$, and
$\tan F = \dfrac{N}{N^2 - {}^1/_4}$ $\sin F = \dfrac{N}{N^2 + {}^1/_4}$ $\cos F = \dfrac{N^2 - {}^1/_4}{N^2 + {}^1/_4}$	$\sin F = \dfrac{\sqrt{4N^2 - 1}}{2N^2}$ $\tan F = \dfrac{\sqrt{4N^2 - 1}}{2N^2 - 1}$ $\cos F = \dfrac{2N^2 - 1}{2N^2}$ Eq (2)

9. To determin the number of an actual frog, Fig 3; find any part of the frog, where the dist, h or t, betw *gage lines* (¶ 2) is unity (say 1 ft, or the length of a pencil or pocket-knife). Then N = dist, hP or tP, from that part to the theoretical frog-point, P (see ¶ 2) measured in the same unit, along the center-line, M, or along a gage-line, S, according to the definition of N adopted (see ¶ 6). Or (since the theoretical frog-point, P, is not easily located) measure *both* widths, h and t (betw *gage-lines*), at any *two* convenient points in opp directions from the frog-point, and the dist, M or S, betw said points. Then,

$$N = \frac{M}{h + t} \quad \text{or} \quad \frac{S}{h + t}.$$ See ¶ 5

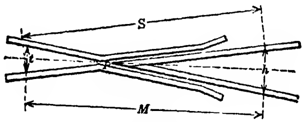


Fig. 3.

10. Actual Frog-Point. Fig 1. In practice, the tongue ends at the "actual frog-point" (or "half-inch point"), where the tongue is about ½" wide; leaving a small isosceles triangle betw the actual and theoretical points. (See ¶ 2). The length of this triangle, or the dist betw the theoretical and actual frog-points, is the product of the actual frog-point width by the frog number, N.

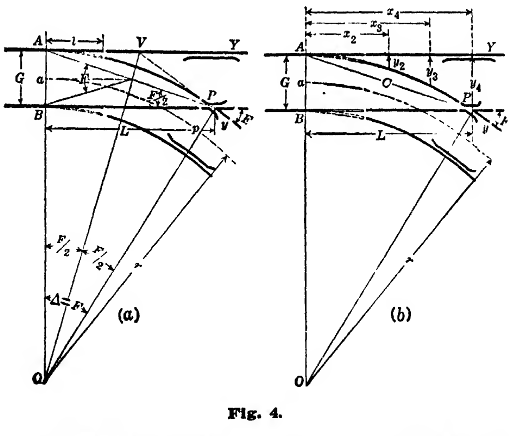

Fig. 4.

11. When angle is small. As an angle, A, approaches zero, as a limit, the values of $A \times \cot A$ ($= A/\tan A$) and of $A \times \csc A$ ($= A/\sin A$) approach unity, A being exprest in radians of 57.295 779°. (¶ 2, p 97). Hence, the same values, exprest in degrees,

approach, as a limit, 57.295 779* (log = 1.758 1226) ; and, in small angles, we have approx :—

for A in degrees, $A^\circ \;=\; 57.3^\circ/\cot A \;=\; 57.3 \sin A$;

$F \;=\; 2 \times 57.3/\cot(F/2) \;=\; 2 \times 57.3 \sin(F/2) \;=\; 57.3/N$.

For A in minutes, $A' \;=\; 3438'/\cot A \;=\; 3438 \sin A$. . (3)

STUB SWITCHES

Circular turnout curv from tangent

General.

12. Fig 4. Let the lead curv, $A\,P$, of the gage side of the outer turnout rail be a simple circular curv, from the beginning, A, of the turnout, to the theoretical frog point, P; said curv being tangential to $A\,Y$ and to $P\,y$, at A and P, respectivly. This condition is seldom perfectly realized in practice; but it is approximately realized, even in point-switches, ¶ 35, and it givs equations which, on account of their simplicity, are sometimes used, not only for stub-switch turnouts, but also (as being sufficiently approx) for point-switch turnouts. They are therefore given below, altho the stub-switch is now used only in subordinate locations.

13. Equations. Fig 4. Stub-switch turnout from tangent. Let

G	$= A\,B$	=	track gage;
r	$= O\,a = O\,A - G/2$ $= O\,B + G/2$	=	turnout center-line radius;
D	....	=	turnout curv sharpness;
Δ	....	=	turnout sweep, from switch-heel, A, to frog-point, P;
F	$= \Delta = B\,P\,V$ $= Y\,V\,P = A\,O\,P$	=	frog angle;
N	$= m/h$, Fig 2, $= \frac{1}{2}\cot(F/2)$ (See ¶ 5)	=	frog number;
L	$= B\,P$	=	lead = frog distance;
C	$= A\,P$	=	outer-rail gage-side chord;
M	....	=	middle ordinate for C;
Q	....	=	quarter-point ord for C;
y_1 (not shown), y_2, y_3, y_4	......	=	perp offsets from tangent to quarter-points of arc, $A\,P$;
x_1 (not shown), x_2, x_3, x_4	......	=	abscissas for offsets, y;
s	(Fig 10).............	=	switch angle;
l	....	=	switch length;
t	....	=	switch throw.

14. Frog angle, F, = turnout sweep, Δ.

Functions of F and of $(F/2)$.

$$\sin F = \frac{L}{r + (G/2)}; \qquad \tan F = \frac{L}{r - (G/2)};$$

$$\cos F = \frac{\sin F}{\tan F} = \frac{r - (G/2)}{r + (G/2)}$$

$$\operatorname{vers} F = \frac{G}{r + (G/2)}. \qquad F = \text{approx } D\,L/100. \quad \ldots.(4)$$

---

*This is also the number of degrees in the angle (= 1 radian) whose arc = radius, and is also the length of the radius of a curv in which an angle of 1° is covered by an arc whose length is unity.

For functions of F in terms of N, see ¶ 8.

$$\text{Cot}\,(F/2) = L/G = 2N = r/GN;$$
$$\text{Tan}\,(F/2) = G/L = 1/(2N) = GN/r. \quad \ldots\ldots\ldots\ldots\ldots (5)$$

15. Frog number, N.

$$N = \frac{\cot\,(F/2)}{2} = \frac{L}{2G} = \frac{r}{L} = \sqrt{\frac{r}{2G}} = \frac{r \tan\,(F/2)}{G}$$
$$= \text{approx } l/(2\sqrt{G\,t}) = \text{approx } 5730°/D°\,L. \quad \ldots\ldots\ldots\ldots (6)$$

16. Turnout center-line radius, r.

$$r = L/\sin F - G/2 = L/\tan F + G/2 = G/\text{vers}\,F - G/2$$
$$= G\,\frac{\cot^2\,(F/2)}{2} = G\,N \cot\,(F/2) = \frac{G\,N}{\tan\,(F/2)}$$
$$= 2\,N^2\,G = L^2/2\,G = N\,L = \text{approx } l^2/2\,t \quad \ldots\ldots (7)$$

17. Turnout center-line sharpness, D.

$$\text{Sin}\,(D/2) = 50/r = 25/N^2\,G\,.$$
$$D = \frac{100\,F}{\text{arc, } a\,p, \text{ ft}} = \text{approx}\,\frac{100\,F}{L, \text{ ft}} = \text{approx}\,\frac{57.3°}{N}\cdot\frac{100}{2NG}$$
$$= \text{approx}\,\frac{2865°}{N^2\,G} = \text{approx}\,\frac{608°}{N^2} \quad \text{for } G = 4 \text{ ft } 8.5 \text{ ins.}$$
$$= \text{approx}\,\frac{5730°}{r, \text{ ft}} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (8)$$

18. Track gage, G.

$$G = \frac{L}{\cot(F/2)} = \frac{L}{2\,N} = \frac{r}{2\,N^2} = \frac{L^2}{2\,r}$$
$$= 2\left(\frac{L}{\sin\,F} - r\right) = 2\left(r - \frac{L}{\tan\,F}\right)$$
$$= \text{approx}\,\frac{l^2}{4\,N^2\,t} = \text{approx}\,\frac{L^2\,t}{l^2} \quad \ldots\ldots\ldots\ldots\ldots (9)$$

19. Lead or frog distance, $L = B\,P$. Fig. 4.

$$L = [r + (G/2)]\sin F = [r - (G/2)]\tan F = G\cot\,(F/2)$$
$$= 2\,G\,N = r/N = \sqrt{2\,r\,G} = 2\,r \tan\,(F/2)$$
$$= (\text{approx, in ft})\ 100\,F/D \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (10)$$

20. Long chord, C ($= A\,P$), to gage-side of outer lead-rail.

$$C = 2\,[r + (G/2)]\sin\,(F/2) = \sqrt{G^2 + L^2}$$
$$= G\sqrt{1 + 4\,N^2} = \text{approx } 2\,r \sin\,(F/2). \quad \ldots\ldots\ldots\ldots (11)$$

21. Offsets, y, from gage-side of main-track rail to gage-side of outer lead-rail.

	A. Exact values of y.	B. Approximate values of y	A/B when $F = 12°$ ($N = 4.76$)*
y_1	$= [r + (G/2)]$ vers $(F/4)$	$= G/16$	1.0034
y_2	$= [r + (G/2)]$ vers $(F/2)$	$= G/4$	1.0027
y_3	$= [r + (G/2)]$ vers $(3\,F/4)$	$= 9\,G/16$	1.0016
y_4	$= [r + (G/2)]$ vers $F = G$		(12)

*With smaller values of F (greater values of N) the approximation for y_1, y_2 and y_3 is closer.

22. Ordinates from long chord, C (= AP) to gage-side of outer rail.

22a. *Middle ordinate, M.*

M = $[r + (G/2)]$ vers $(F/2)$
= approx $G/4$ = approx $14\frac{1}{8}$ ins when G = 4 ft 8.5 ins.

When N =	4	8	16	
we find $M/(G/4)$ =	1.0039	1.0010	1.000244	......(13)

22b. *Quarter-point ordinate, Q.*

$$Q = \sqrt{[r + (G/2)]^2 - (C/4)^2} + M - (G/2) - r \quad ..(14)$$

$$\text{where } C/4 = \frac{[r + (G/2)] \sin (F/2)}{2}$$

Q = approx $3\,G/16$ = approx $0.1875\,G$
= approx 10.6 ins when G = 4 ft 8.5 ins ....(15)

When F = 12°, (N = 4.76),

$$\frac{Q}{3\,G/16} = 1.0035.$$

With smaller values of F (greater values of N), the approximation is closer.

23. In stub-switch turnouts, the middle and quarter point ordinates are *nearly independent of the frog-angle, F.* When N = 4, N = 16, and gage = 4 ft 8.5 ins the middle ords, to gage side of outer rail, compare as follows:

$$\frac{\text{mid ord, } N = 4}{\text{mid ord, } N = 16} = \frac{1.18165 \text{ ft}}{1.17737 \text{ ft}} = 1.00363$$

But see ¶ 38.

24. Switch angle, s, length, l, and throw, t. For the relation betw these we may take

$t = l \sin s$ ....(16)

25. Dimensions. Circular Turnout from Tangent. Fig 4.

Gage, 4 ft 8.5 ins = 4.70833... ft.
Switch-throw = 5.5 ins = 0.45833... ft.

N = frog number; C = AP = chord;
F = frog angle; L = BP = lead;
r = turnout center-line radius; l = switch-rail length;
D = turnout sharpness; t = throw.

N	F	r	$\log r$	D	C	L	$l = 2N\sqrt{Gt}$

Turnout from Curv.

26a. Fig 5*b*. For stub-switch turnouts from tangents, ¶ 25 gives the sharpness, D, the radius, r, and the lead, $L, = B\,P$, for frog numbers from 4 to 16. The middle ordinate,

$$M = \left(r + \frac{G}{2}\right) \text{vers} \frac{F}{2},$$ from the chord $A\,P$ to the turnout frog-rail gage-side, is practically the same for all frog numbers. See ¶ 23.

26b. But, Figs 5*a* and 5*c*, when a given frog number is used in a turnout from a *curvd* main track, all these functions (including the ordinates) are affected; and their values depend not only upon the sharpness, D_m, of the main-track curv, but also upon whether the turnout curvs in the same direction with the main-track curv, Fig 5*a*, or in the opposit direction, Fig 5*c*.

27. Symbols. Figs 5. Let

G = gage; F = frog angle; $N = \frac{\text{Cot } (F/2)}{2}$ = frog number.

and let other symbols denote as follows:

	For curvd main track Figs 5*a*, *c*	For turnout from tang Fig 5*b*	For turnout from curv Figs 5*a*, *c*
Center	O_m	O	O_c
Center-line radius	r_m	r	r_c
Sharpness	D_m	D	D_c
Sweep, from beginning, *a*, of turnout, to frog-point, *P*,	Δ_m	Δ	Δ_c
Ordinates, from long chord, *A P*, to turnout frog-rail gage-side			
Middle-ordinate	— - -	M	M_c
Quarter-point ordinate	---	Q	Q_c
Lead, *B P*,	--- --	L	L_c

28. Relations. Then, comparing first Fig 5*a* and then Fig 5*c* with Fig 5*b*, we find, for a given frog angle, F:—

Fig 5*a*, when the two curvs are in the *same* direction,

$D_c > D;\ r_c < r;\ L_c < L;\ M_c > M.$

Fig 5*c*, when the two curvs are in *opposit* directions,

$D_c < D;\ r_c > r;\ L_c > L;\ M_c < M.$

29. Sharpness Difference. Figs 6. Let the sharpness of the main-track curv, $M\,M'$, be D_m, and let that of the turnout curv, T be D_c. (In Fig 6*b*, $D_m = 0$.)

Figs. 7.

Then, for their sharpness difference, D_d, we have :—

$D_d = D_c \pm D_m$; plus for Fig 6 *c;* minus for Fig 6 *a;*

or

$D_c = D_d \pm D_m$; plus for Fig 6 *a;* minus for Fig 6 *c.* (17)

If (Fig 7 *c*) the main track has the *sharper* curv, or $D_m > D_c$, we hav: D_d $(= D_c - D_m)$ negativ, and $D_c = D_m - D_d$.

Eqs (17), above, are exact, when D = sweep per *arc* unit. See Curvs p 878, ¶ 20.

·30a. Arrangements. Let Figs 7 represent a series of turnouts, T (shown dotted) each leaving the main track (shown solid) on the right, with constant frog angle, F*;* and, beginning with Fig 7*a*, let the main track deflect progressively toward the left. We then have :—

	Fig				
	7*a*	7*b* $r_m = \infty$; $\Delta = F$	7*c* $r_m = r_c$	7*d* $r_c = \infty$; $\Delta_m = F$	7*e*
Cens (and deflection from tangent in our Figs)					
Main —, O_m	right	0	left	left	left
Turnout —, O_c	right	right	right	0	left
Turnout leavs main track on	inside		outside	outside	outside
Frog rail					
Main —, BP	inner		outer	outer	outer
Turnout —, AP	outer	outer	outer		inner
Radii					
Greater	main	main		turnout	turnout
Main —, r_m	incrsg	∞	decrsg	decrsg	decrsg
Turnout —, r_c	increasing			∞	decrsg
Sweeps					
Main —, Δ_m	decrsg	0	increasing		
Turnout —, Δ_c	decreasing			0	incrsg

30b. We see, therefore, that a turnout may be a tangent, Fig 7*d*, or a curv in either direction; and that, if a curv, it may leav

Fig 7 *b*, a main-track tangent, as in our preceding articles;

Fig 7 *c*, a main-track curving in the *opp* dir'n, (cens on *opp* sides of track);

Figs 7 *a*, *e*, a main-track curving in the *same* dir'n, (cens on *same* side of track).

30c. When the turnout is a tangent (Fig 7*d*), it necessarily leavs the *outside* of the main-track curv; and the frog angle, F, is then the same (= turnout sweep, Δ_m) as for a turnout (Fig 7 *b*) of radius $r = r_m$, Fig 7 *d*, leaving a main-track tangent.

30d. When the two curvs are in opp directions (Fig 7c), (centers, O_m and O_c, on *opp* sides of the track), the turnout curv also necessarily leavs the *outside* of the main-track curv.

30e. When the two curvs are in the same direction (Figs 7 *a*, *e*) (cens, O_m and O_c, on *same* side of track) the turnout may leav either the inside or the outside of the main-track curv; but we assume (Fig 7 *a*) that, in this case, unless otherwise specified or obvious, the turnout curv has the shorter radius, so that it leavs the *inside* of the main-track curv.

31a. Equations for turnouts from curvs. For symbols, see ¶ 27.

For approximate equations, see ¶ 31 *b*.

$$\pm\,\Delta_m = F \pm \Delta_c\dagger; \qquad \pm\,\Delta_c = F \pm \Delta_m\dagger; \quad \ldots\ldots\ldots\ldots (18)$$

$$\operatorname{Tan}(\Delta_m/2) = G\,N/r_m; \qquad \operatorname{Tan}(\Delta_c/2) = G\,N/r_c; \quad \ldots\ldots\ldots\ldots (19)$$

$$\pm\,F = \Delta_c \pm \Delta_m;^* \qquad N = \tfrac{1}{2}\cot(F/2); \quad \ldots\ldots\ldots\ldots (20)$$

$$r_m = \frac{50}{\sin(D_m/2)} = \frac{G\,N}{\tan(\Delta_m/2)}; \quad \ldots\ldots\ldots\ldots (21)$$

$$r_c = \frac{50}{\sin(D_c/2)} = \frac{G\,N}{\tan(\Delta_c/2)} = \left(r_m \pm \frac{G}{2}\right)^* \frac{\sin\Delta_m}{\sin\Delta_c} - \frac{G}{2}; \quad (22)$$

$$\sin(D_m/2) = 50/r_m; \qquad \sin(D_c/2) = 50/r_c;$$

$$D_d = D_c \pm D_m;^* \quad \ldots\ldots\ldots\ldots (23)$$

$$L_c = 2\left(r_m \pm \frac{G}{2}\right)^* \sin\frac{\Delta_m}{2}; \quad M_c = \left(r_c + \frac{G}{2}\right)\operatorname{vers}\frac{\Delta_c}{2}; \quad (24)$$

$$Q_c = \sqrt{R_c^2 - x^2} + M_c - R_c \quad \ldots\ldots\ldots\ldots (25)$$

where $R_c = r_c + (G/2)$; $\quad x = A\,P/4 = \tfrac{1}{2} R_c \sin(\Delta_c/2)$

31b. Approximate equations. Fig 6. For a circular turnout from a curv, the principal functions may be found approximately, as below, by comparison with the corresponding functions in a turnout from a tangent.

With given gage, G, and given frog number, N, let the following nomenclature be observd.

---

*Plus for curvs in opposit direction; minus for curvs in same direction.

†Plus for curvs in same direction; minus for curvs in opposit direction.

	In turnout from tangt	In turnout from curv	
		Correct	Approx
Cen-line radius			
of main line,	$r_m (= \infty)$	r_m	...
of turnout,	r	r_c	r_{ca}
Sharpness			
of main line,	$D_m (= 0)$	D_m	...
of turnout,	D	D_c	D_{ca}
Sharpness-diff,	$D_d (= D)$	D_d $(= D_c \pm D_m)$*	D_{da}
Lead,	L	L_c	L_{ca}
Ordinate,			
middle—,	M	M_c	M_{ca}
quarter-point—,	Q	Q_c	Q_{ca}

Then, for a given gage, G, and given frog number, N, we have:—
Approx; see ¶ 31c

$$D_{da} = D; \quad D_{ca} = D_{da} \pm D_m\dagger; \quad r_{ca} = 50/\sin \tfrac{1}{2} D_{ca}$$

$$L_{ca} = L; \quad M_{ca} = M\,(1 \pm D_m/D)\dagger; \quad Q_{ca} = Q\,(1 \pm D_m/D)\dagger \quad (26)$$

31 c. The following table shows the *degree of approximation* in the approx equations (26), ¶ 31 *b*

						
	$D_m = 2°$	$D_m = 4°$	$D_m = 8°$	$D_m = 2°$	$D_m = 4°$	$D_m = 8°$
N	D_d/D	D_d/D	D_d/D	D_d/D	D_d/D	D_d/D
4	1.0042	1.0088	1.0196	0.99627	0.99299	0.98773
8	1.0019	1.0044	1.0115	0.99878	0.99821	0.99902

	M_c/M_{ca}		M_c/M_{ca}	M_c/M_{ca}		M_c/M_{ca}
4	1.0013	....	1.0043	0.99851	....	0.99305
16	0.99990	....	0.99285	0.99896	....	0.99368

*Plus for curvs in opposit direction; minus for curvs in same direction.

†Plus for curvs in same direction; minus for curvs in opposit direction.

‡With $D_m = 8°$, $N = 16$, the turnout, from outside of main track curv, curvs in the same direction, see Fig 7 *e*; *i. e.*, the two centers are on the same side of the track. See ¶ 30 *e*.

Double Turnout from Tangent.

From Opposit Sides.

32. Fig 8. In a double stub-switch turnout (see Part I, ¶10) from opposit sides of a tangent, let the two turnout curvs be of equal sharpness; and let

$G = AB =$ gage;

$F = F_a = F_b =$ main frog angle; $F_c =$ crotch frog angle;

$N = N_a = N_b =$ main frog number; $N_c =$ crotch frog number;

$L = A P_a = B P_b =$ main frog lead;

$L_c = a P c =$ crotch frog lead;

$r = O_a a = O_b a =$ center-line radius of either turnout curv;

$R = O_a B = O_b A = O_a P_a = O_b P_b = O_a P_c = O_b P_c = r + G/2$ = outer-rail gage-side radius of either turnout curv.

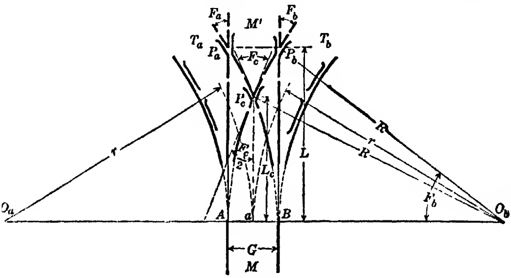

Fig. 8.

Then,

$F_c = 2 P_c O_b a$;

$L = 2 G N$ (see ¶ 19); $\quad L_c = 2 \left[G + \frac{(G/2)^2}{r} \right] N_c$

$$= \frac{G + \frac{(G/2)^2}{r}}{\tan(F_c/2)} \quad \ldots\ldots\ldots\ldots (27)$$

Or, for L_c, we have:—

$$\frac{L_c}{L} = \sqrt{\frac{R^2 - (R - G/2)^2}{R^2 - (R - G)^2}} = \sqrt{\frac{R - G/4}{2R - G}} \quad \ldots\ldots\ldots\ldots (28)$$

Hence, neglecting G, we have, approx:—

$L_c = \sqrt{1/2}\, L = 0.707\, L = \sqrt{2}\, G N$;

$L - L_c =$ approx $(1 - \sqrt{1/2})\, L =$ say $0.293\, L$;

or, practically, $L_c = 0.7\, L$; and $L - L_c = 0.3\, L$; ......(29)

$$N_c = \frac{\cot(F_c/2)}{2} = \frac{L_c}{2\,[G + (G/2)^2/r]}$$

$$= \text{app} \frac{L_c}{2G} = \frac{\sqrt{2}\, G N}{2G} = \frac{N}{\sqrt{2}} = 0.707\, N \quad \ldots\ldots\ldots\ldots (30)$$

From Same Side.

33. Fig 9. Two stub-switch turnouts, T_a and T_b, with center-line radii, r_a and r_b, respectivly, from the same side of the tan, $M\,M'$.

Let $R_a \;(= O_a A = r_a + G/2) = 2\,R_b = 2\,(O_b A) = 2\,(r_b + G/2)$.

Then, since $O_b P_b = O_b O_a$, we have:

$$F_a = F_b = F = \text{main-frog angle};$$
$$N_a = N_b = N = \text{" number}; \quad \ldots\ldots\ldots (31)$$

and the two main-frog points, P_a and P_b, are opposit, on track, T_a.

Let D_a and D_b be the center-line sharpnesses of curvs, T_a and T_b, respectivly.

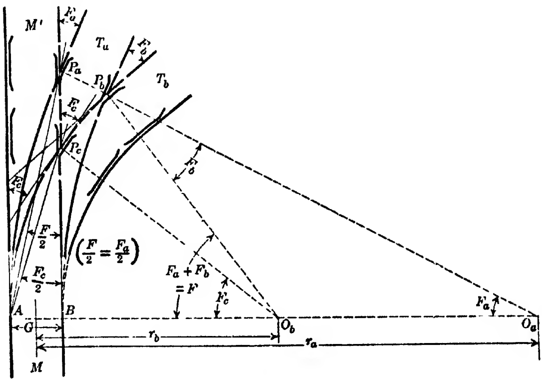

Fig. 9.

Then, approx:—

$D_b = 2\,D_a;$

$\text{Vers}\,F_c = G/R_b = 2\,G/R_a;$

$L = B\,P_a = \text{lead} = R_a \sin F_a = 2\,G\,N;$

$L_c = B\,P_c = \text{crotch-lead} = R_b \sin F_c = 2\,G\,N_c = \sqrt{0.5}\;L$
$= \sqrt{2}\;G\,N;$

$$N_c = \frac{L_c}{2\,G} = \frac{\cot\,(F_c/2)}{2} = 0.707\,N. \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots (32)$$

Double Turnouts from Curv.

34. In double turnouts from the same side or from opp sides of a curvd main track of moderate sharpness, the dimensions are practically the same as for similar turnouts from straight track, using the same frog angles. If the main-track curvature is sharp, the problem may be solvd graphically.

POINT SWITCHES

Turnout from Tangent.

35. Nomenclature. Fig 10. Point-switch turnout from tangent. Compare Am Ry Engng Assn, Manual, 1915, pp 182-3.

Let

G		=	track gage;
R	OD	=	outer-rail gage-side radius of turnout curv, DE;
r	$OD - G/2$	=	cen-line rad of turnout curv, DE;
D		=	sharpness of turnout curv, DE;
Δ	DOE	=	sweep of turnout curv, DE, betw switch-heel and frog-toe;
M		=	middle ordinate from chord, DE, to outer-rail gage-side;
F	$= BPE = tOE$	=	frog angle;
N	$= \frac{1}{2}\cot(F/2)$	=	frog number;
C	$= DE$	=	long chord of outer-rail gage-side;
L	$= BP$	=	lead, from actual switch-point to theoret frog-point;
T	$= DV = VE$	=	semitangent of turnout curv;
s	$= YAD$	=	switch angle;
l	$= AD$	=	switch length;
S		=	switch-heel distance, or spread, betw gage-lines, at D;
W	$= PE$	=	dist from frog-point to frog-toe;
e		=	$G - S - W \sin F$;
p		=	actual switch-point thickness;
t		=	actual frog-point thickness;
$x, y,$	$= ti, tk$	=	co-ordinates of any given point, as n, on outer-rail gage-side;
a	$= DOn$	=	sweep of arc, Dn.

36. Equations for point-switch turnout from tangent.

Fig 10. *Frog angle, F; turnout sweep, Δ, and switch angle, s.*

$F = \Delta + s; \quad \Delta = F - s;$

$s = F - \Delta. \quad \operatorname{Sin} s = (S - p)/l;$ ....(33)

Lead, L.

$$L = (l - W)\frac{\sin \frac{1}{2}(F - s)}{\sin \frac{1}{2}(F + s)} + (G - p)\cot\frac{F + s}{2}$$

$$= (T + l)\cos s + (T + W)\cos F \quad \text{..............(34)}$$

For *lead from vertex to theoretical switch point*, add $p \cot s$.

For *lead to actual frog point*, add $N t$, t = actual frog-point thickness.

Since $T \sin s + T \sin F = T(\sin s + \sin F) = e$, we have:—

$$T = R\tan(\Delta/2) = \frac{e}{\sin s + \sin F} \quad \text{........(35)}$$

Turnout center-line radius, r.

Since $e = DE \sin \frac{1}{2}(F + s)$

$= 2R\sin(\Delta/2) \sin \frac{1}{2}(F + s)$, we have:—

$$R = r + G/2 = T\cot(\Delta/2)$$

$$= \frac{e}{2\sin \frac{1}{2}(F + s)\sin(\Delta/2)} = \frac{e}{\cos s - \cos F}; \text{ and}$$

$= \quad R \quad - \quad G/2$ ....(36)

Chord, D E $\quad = \quad 2\,R \sin(\Delta/2)$ ....(37)

Turnout curv sharpness, D.

$\sin(D/2) \quad = \quad 50/r$ ....(38)

Arc, D E.

$DE \quad = \quad 2\,\pi\, R\,\Delta°/360 \quad = \quad 0.017\,453\,R\,\Delta°$ ....(39)

Distance, D′ E′, from switch-heel, *D′*, to frog-toe, *E′*.

$D'E' \quad = \quad L \quad - \quad (W \; + \; l)$ ....(40)

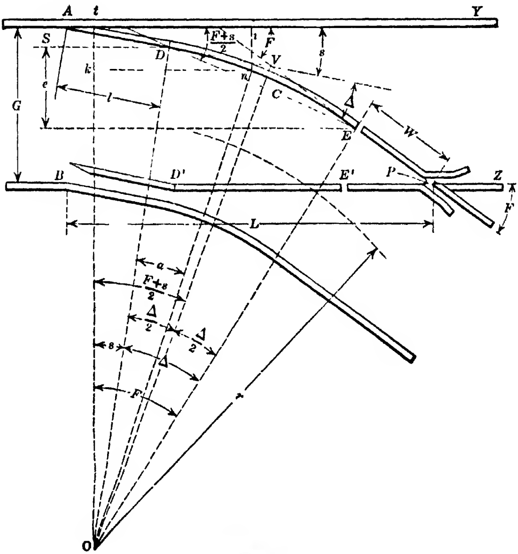

Fig. 10.

Co-ordinates, $x \quad = \quad k\,n$; and $y \quad = \quad i\,n$.

$x\;(= \;kn) \quad = \quad [l \cos s \; - \; R \sin s] \; + \; R \sin(a \, + \, s)$;

$y\;(= \;in) \quad = \quad [S \; + \; R \cos s] \; - \; R \cos(a \, + \, s)$..(41)

The quantities in brackets are constant for a given *N*, *l* and *s*.
The Am Ry Engng Assn, Manual, 1915, p 184, specifies:—

Switch-point thickness, *p*,	=	0.25 inch	=	0.020 833...ft;
Frog-point thickness, *t*,	=	0.50 inch	=	0.041 666...ft;
Switch-heel dist, or spread, *S*,	=	6.25 ins	=	0.520 833...ft.

Middle ordinate, *M*, to outer-rail gage-side.

$M = R \operatorname{vers}(\Delta/2)$ ....(42)

37. Simple approximate equations, using "switch-number", n. Fig 11. (Compare Wellington B. Lee, Eng News, 1898 Apl 21, p 252.)

Let

G	=	gage;
W	=	dist from frog-toe to frog-point;
F	=	frog angle;
l	=	switch length;
S	=	switch-heel distance;
N	=	frog number;
n	=	l/S = "switch-number";
e	=	$G - S - W \sin F$;
C	=	chord, $D\,E$, from switch-heel to frog-toe.

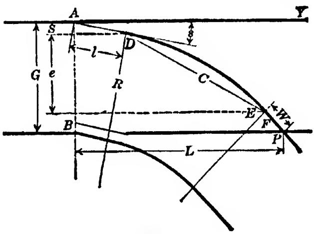

Fig. 11.

Then :—

$$C \text{ approx} = 2\,e\,\frac{n\,N}{n + N}\,; \qquad (43)$$

$$R = r + \frac{G}{2}\,; \quad R \text{ approx} = C\,\frac{n\,N}{n - N}$$

$$= \text{outer-rail gage-side radius.} \qquad (44)$$

With gage, G, = 4′ 8.5″, and S = 6.25″, calculation shows:

N =	l =	W =	F =	s =	$R - R_{app}$	R/R_{app}
4	11 ft	3 ft 2″	14° 15′ 0″	2° 36′ 19″	3.25 ins	1.0024

Ordinates to chord, C.

38. Where, as assumed, for the *stub* switch, in ¶ 12, Figs 4, the outer turnout rail forms a continuous circular curv, from beginning, A, of turnout to the theoretical frog-point, P, its middle and quarter-point ordinates are approximately independent of the frog number, N (and hence independent of the radius); but, where, as in point-switches, Fig 10, the turnout curv is tangential to the switch-rail and to the frog-leg, at D and at E, respectivly, the ords diminish as the frog-angle, F, diminishes; and they would become zero if the frog-angle, F, became = the switch-angle, s; for the turnout-curv would then become a straight line.

$$\text{Mid ord} = R \text{ vers } \frac{\Delta}{2} = \left(r + \frac{G}{2}\right) \text{vers } \frac{\Delta}{2}. \quad \text{See Eq (42).}$$

"Theoretical" and "practical" dimensions.

39. To reduce rail-cutting and rail-waste, it is commonly found desirable to depart from the "theoretical" dimensions given by eqs 34-41, and represented by the *solid* lines in Figs 12, and to make the straight lead-rail, $D' \, E'$, of such length, $D_p' \, E'$, as to permit the eventual utilization of both the pieces into which a rail is cut; thus substituting "practical" for the "theoretical" dimensions.

40. The curvd lead-rail, ($D_p \, E_p$, Fig12*a*; $D_p'' \, E$, Fig12*b*) may then be made of the same number and lengths of pieces with $D_p' \, E'$, bringing the joints of these two rails opposit, if the length excess of the curvd rail may be compensated by laying it with joint-spaces wider than those of $D_p' \, E'$. But compare tables of theoretical and practical dimensions, ¶ ¶ 47-50.

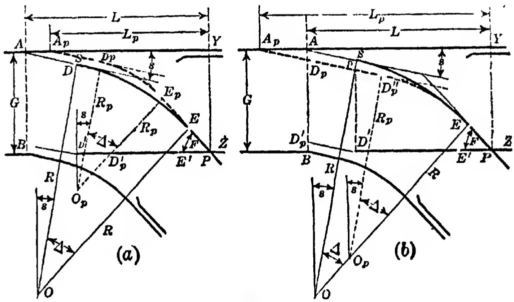

Fig. 12.

41. Diagrams. In Figs 12*a*, 12*b*, the *"theoretical"* dimensions are shown in *solid* lines; and the *"practical"* dimensions of the outer turnout rail are shown in *dotted* lines. Fig 12*a* represents the case where the "theoretical" lead, L, *exceeds* the "practical" lead, L_p; and Fig 12*b*, *vice versa.*

42. Change in lead length. Figs 12*a*, 12*b*. With a given switch-length, $l = A \, D$, given switch-angle, $s = Y \, A \, D$, and given frog-angle, F, there is but one lead length, L, and but one outer-rail gage-side radius, $R = O \, D$, for a circular arc, $D \, E$, connecting tangentially the switch-heel, at D, and the frog-toe, at E.

43. If the lead be *shortend* (as to L_p, Fig 12*a*) we must introduce an additional *"frog tangent"*, $E \, E_p$; whereas, if the lead be *lengthend* (as to L_p, Fig 12*b*), we must introduce an additional *"switch tangent"*, $D_p \, D_p''$. In *either* case, the *radius* is *shortend*, as indicated.

44. New Radius. For the new (diminisht) outer-rail gage-side radius, R_p, and for the additional tangents, we have (S. S. Roberts, Track Formulæ and Tables, pp 12-13).

Fig 12*a*

$$R - R_p = (L - L_p) \frac{\sin F \times \cot \frac{1}{2} (F - s)}{\sin (F - s)} ;$$

$$E \, E_p = (L - L_p) \frac{\sin \frac{1}{2} (F + s)}{\sin \frac{1}{2} (F - s)} \quad \ldots\ldots\ldots\ldots\ldots (45)$$

Fig 12b

$$R \; - \; R_p \; = \; (L_p \; - \; L) \; \frac{\sin s \times \cot \frac{1}{2}(F - s)}{\sin (F - s)} \; ;$$

$$D_p D_p'' \; = \; (L_p \; - \; L) \; \frac{\sin \frac{1}{2}(F + s)}{\sin \frac{1}{2}(F - s)} \; \ldots\ldots\ldots\ldots\ldots (46)$$

45. Co-ordinates. For a given point in the lead curv,

Let x = the abscissa (co-ordinate *parallel* with main track), measured from the switch-point, A_p,

y = the ordinate or offset (co-ordinate *normal* to main track) measured normally from the tangent.

In Fig 12a, where the theoretical exceeds the practical lead, the co-ords, x and y, to any point in the lead curv, $D_p E_p$, are as in eq 41, substituting R_p for R; but, in Fig 12b, where the practical exceeds the theoretical lead, these co-ords are modified, as below, by the introduction of the switch-tangent, $D_p D_p''$. (S. S. Roberts; Track Formulæ and Tables, p 13.) Here, l = switch-length, $A D$; S = switch-heel spread; s = switch-angle, $Y A D$; Δ_p = turnout sweep from switch-heel to the given point. The quantities in brackets [ ] are constant for given N, l and s.

$$x \; = \; [(l + D_p D_p'') \cos s - R_p \sin s] \; + \; R_p \sin(\Delta_p + s)$$

$$= \; (\text{approx}) \; [(l + D_p D_p'') - R_p \sin s] \; + R_p \sin(\Delta_p + s) \; ;$$

$$y \; = \; [S + D_p D_p'' \sin s + R_p \cos s] \; - \; R_p \cos(\Delta_p + s) \ldots (47)$$

46. Frogs and Switches. Am Ry Engng Assn, Manual, 1915, pp 184-5. Our Figs 1, 10 and 13. For theoretical and practical leads, see ¶¶ 48-50.

S = switch-heel spread = 6.25 ins;
N = frog number; F = frog angle;
W = dist, point to toe of frog, measured parallel with a gage-line;
K = dist, point to heel of frog; T = frog-toe spread;
H = frog-heel spread; l = switch-rail length;
s = switch angle

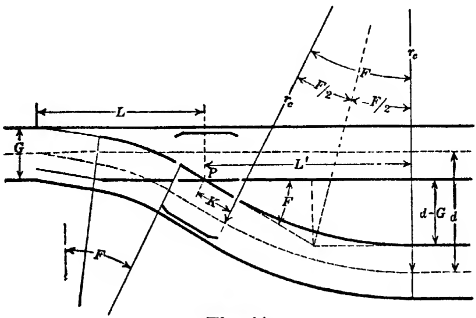

Fig. 14.

Connecting Curv.

51. Lateral Turnout. Fig 14. In the "lateral" turnout, let d = dist betw cens of tracks; $d - G$ = dist betw gage-lines of inner tracks; K = dist from theoret frog-point to frog-heel; r_c = cen-line radius of connecting curv; L' = lead from theoret frog-point to end of connecting curv. Then, remembering that

$$2N = \cot(F/2) = 1/\tan(F/2),$$

we have

$K + (r_c - G/2)\tan(F/2) = (d - G)/\sin F;$ **hence :—**

$r_c = 2N(d - G)/\sin F - 2NK + G/2;$

$L' = (d - G)\cot F + (r_c - G/2)/2N$ .... (48)

52. Diamond or Equilateral Turnout. Fig 15. In the "diamond" or "equilateral" turnout, we have :—
(compare Lateral turnout, ¶ 51.)
r = turnout curv cen-line radius, $O_t c$.

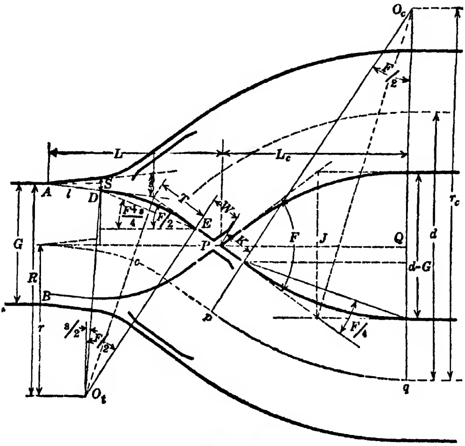

Fig. 15.

$$R\ (= r + G/2) = O_t D = T^*\cot\frac{F - s}{4} = \frac{DE^*}{2\sin\frac{1}{4}(F - s)}$$ .... (49)

$L = (T + l) \times \cos(s/2) + (T + W) \times \cos(F/2)$ .... (50)

Comparison of Dimensions between a diamond turnout and a turnout from straight track, with given frog and switch angles.
With F = 8° (N = 7.15); s = 2°; G = 4′ 8.5″ = 4.70833... ft; l = 16 ft; S = 0.5 ft; W = 5 ft;

	Diamond	Straight	Diamd/Strt
T	20.1285	20.1782	0.9975
R	768.6760	385.0226	1.9964
L	61.1903	61.0893	1.0017

$$^*T = \frac{G/2 - S/2 - W\sin(F/2)}{\sin(s/2) + \sin(F/2)};$$

$$DE = \frac{G/2 - S/2 - W\sin(F/2)}{\sin\frac{1}{4}(F + s)} = 2R\sin\tfrac{1}{4}(F - s)$$

53. Radius and Lead. Fig 15. Radius, r_c, and lead, L_c, of connecting curv, $p\,q$, for diamond turnout.

Let

$d - G$ = dist betw gage-sides of inner rails;

$r_c = O_c\,p$ = center-line radius of connecting curv, $p\,q$;

K = dist from frog-heel to theoret frog-point, P;

$L_c = P\,Q$ = lead, from theoret frog-point to end of connecting curv;

F = frog angle; N = frog number $= \frac{1}{2}\cot(F/2)$.

Then

$(r_c - G/2)\,\mathrm{vers}(F/2) = (d - G)/2 - K\sin(F/2)$. Hence,

$$r_c = \frac{d - G}{2\,\mathrm{vers}(F/2)} - \frac{K}{\tan(F/4)} + G/2; \quad \ldots\ldots\ldots\ldots\ldots\ldots (51)$$

$$L_c = P\,J + J\,Q = N\,(d - G) + (r_c - G/2) \times \tan(F/4) \quad \ldots (52)$$

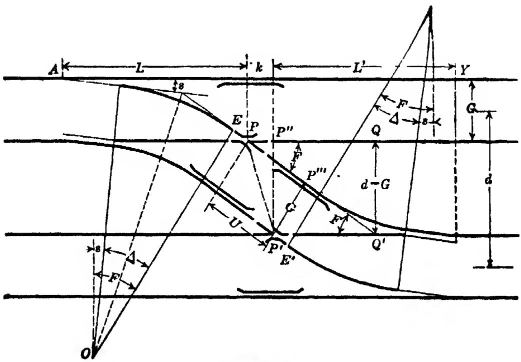

Fig. 16.

Crossovers.

54. Figs 16, 17. When the connecting track is a tangent (Fig 16), the two frog angles are necessarily equal. When it is a reverse curv (Fig 17) they are preferably equal.

With straight connecting track, $E\,E'$. Fig 16. Let

$R = O\,E$ = outer-rail gage-side radius of turnout curv;

T = semitangent of turnout curv;

d = dist betw main-track center-lines;

G = track-gage;

$d - G$ = dist betw gage-lines of inner rails;

$k = PP'' =$ dist betw theoret frog-points, P and P', $\parallel$ with main tracks;
$U = PP''' =$ dist betw theoret frog-points, P and P', $\parallel$ with connecting track;
$W =$ dist from theoret frog-point, P, to frog-toe, E;
$l =$ switch-length.

Then :—

$T = R \tan(\Delta/2)$; $L = L' = (T + l) \cos s + (T + W) \cos F$;

$$k = PQ - P'''Q = PQ - P'Q' = \frac{d - G}{\tan F} - \frac{G}{\sin F};$$

$AY = L + k + L' = k + 2L$;

$$U = PQ' - P'''Q' = \frac{d - G}{\sin F} - \frac{G}{\tan F}. \quad \ldots\ldots\ldots\ldots\ldots\ldots (53)$$

For unit change in the value of d, the corresponding changes in k and in U, respectivly, are :—in k, change $= \cot F$; in U, change $= \operatorname{cosec} F$.

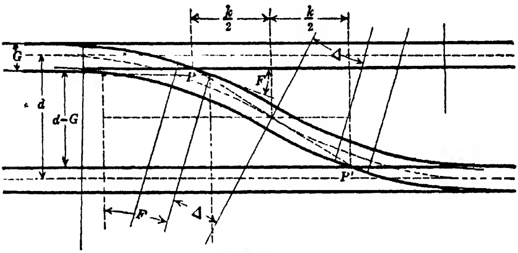

Fig. 17.

55. With reverst connecting curv. Fig 17.

The use of a reverst connecting curv economizes space, especially where the two tracks are spaced wide apart and where the frog-angle is small. The radius is usually that of the turnout curv.

Let

$F =$ frog angle;
$\Delta =$ sweep of either branch of reverst connecting curv;
$r =$ center-line radius of reverst connecting curv;
$R = r + G/2$
$=$ outer-rail gage-side radius of reverst connecting curv;
$K =$ dist, from theoret frog-point, P, to frog-heel.
$k =$ dist, parallel with track, betw frog-points, P and P'.

Then :—

$r \cos(F + \Delta) = R \cos F + K \sin F - (d - G)/2$;
$k/2 = r \sin(F + \Delta) - R \sin F + K \cos F$;
$PP' = \sqrt{k^2 + (d - G)^2}$ $\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots$ (54)

Double Turnout.

56. Fig 18. Double point-switch turnout from opp sides of tangent. Let the two main frogs, P, be of equal angle and therefore opp, and let

r = turnout center-line radius;
R = $OE = r + G/2$ = outer-rail gage-side radius;
Δ_c = sweep, $D\,O\,P_c$;
T_c = semitangent of curv $D\,P_c$;
W = $E\,P$ = dist from main frog-toe, E, to theoret frog-point, P;
S = switch-heel spread;
s = switch angle;
l = $A\,D$ = switch length;
N, F, = main frog number and angle;
N_c, F_c = crotch frog number and angle;
$L = B\,P$ = lead to main frog, P;
$L_c = a\,P_c$ = lead to crotch frog, P_c.

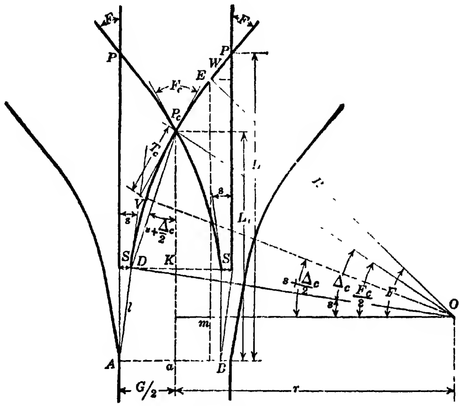

Fig. 18.

Then :—

$$\frac{F_c}{2} = \Delta_c + s; \qquad D\,P_c\,a = V\,O\,m = s + \frac{\Delta_c}{2} = \frac{F_c - \Delta_c}{2};$$

$$\operatorname{Cos}\frac{F_c}{2} = \frac{r}{R} = \cos F + \frac{G/2 - W \sin F}{R}; \qquad \cos F = \frac{O\,m}{R};$$

$$N_c = \frac{\cot(F_c/2)}{2};$$

$$T_c = \frac{G/2 - S}{\sin s + \sin(F_c/2)}$$

$$D\,P_c = \frac{G/2 - S}{\sin(s + \Delta_c/2)} = 2\,R \sin\frac{\Delta_c}{2};$$

$$R = \frac{D\,P_c}{2\sin(\Delta_c/2)} = T_c \cot(\Delta_c/2) = \frac{G/2 - S}{2\sin(\Delta_c/2)\sin(s + \Delta_c/2)}$$

$$L_c = L - W\cos F - R\,[(\sin F - \sin(F_c/2)]$$

$$= aK + KP_c$$

$$= l\cos s + (G/2 - S)\cot\frac{F_c - \Delta_c}{2}$$

$$= (T_c + l)\cos s + T_c\cos(F_c/2)\ \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (55)$$

Ladders.

57. Layout. Fig 19. Ordinarily, the yard or "body" tracks, 2, 3, 4, etc., reacht by a ladder, are parallel with the main (or "drill") track, 1; the ladder is straight, from P_1 to P_4, etc; the yard tracks, 2, 3, 4, etc., are straight from the ladder frogs, P_2, P_3, etc., and the dist, *d*, betw cens of adjacent parallel tracks is constant.

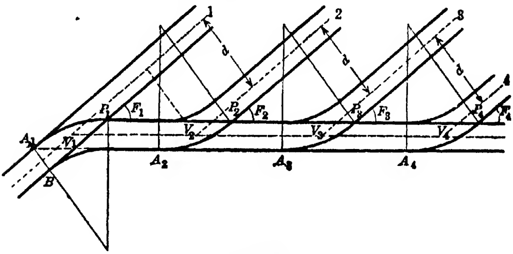

Fig. 19.

58. Distances. The frog angles, F_1, F_2, etc., betw drill track and ladder, and betw ladder and yard tracks, are then equal; and the dists, A_1A_2, A_2A_3, etc., betw consecutiv switches; those, P_1P_2, P_2P_3, etc., betw consecutiv frogs; and those, V_1V_2, V_2V_3, etc., betw consecutiv intersections, measured ‖ with the ladder, are all equal, and $V_1V_2 = d/\sin F$. (But see ¶ 60.) For unit change in the value of *d*, the corresponding change, in $d/\sin F$, is $1/\sin F = \operatorname{cosec} F$.

59. The *minimum allowable dist,* along the ladder, betw a frog point, as P_1, and a point opp the switch-toe, A_2, of the next turnout, is about 10 ft.

60. "Under ordinary conditions, *body tracks should be spaced* 13 to 14 ft centers, and, where they are parallel to main track or to other important running track, the first body track should be spaced $\nless$ 15 ft centers from such main or other important track. Ladder tracks should be spaced $\nless$ 15 ft centers from any parallel track." Am Ry Engng Assn, Manual, 1915, p 469.

61. Frog Numbers. Steam railroad yards commonly use No 7 and No 8 frogs; less commonly No 6. For general use in ladders, the Am Ry Engng Assn (Manual, 1915, p 469) recommends frogs of not lower No than No 8.

Double Turnout.

56. Fig 18. Double point-switch turnout from opp sides of tangent. Let the two main frogs, P, be of equal angle and therefore opp, and let

r = turnout center-line radius;
R = $OE = r + G/2$ = outer-rail gage-side radius;
Δ_c = sweep, $D\,O\,P_c$;
T_c = semitangent of curv $D\,P_c$;
W = $E\,P$ = dist from main frog-toe, E, to theoret frog-point, P;
S = switch-heel spread;
s = switch angle;
l = $A\,D$ = switch length;
N, F, = main frog number and angle;
N_c, F_c = crotch frog number and angle;
L = $B\,P$ = lead to main frog, P;
L_c = $a\,P_c$ = lead to crotch frog, P_c.

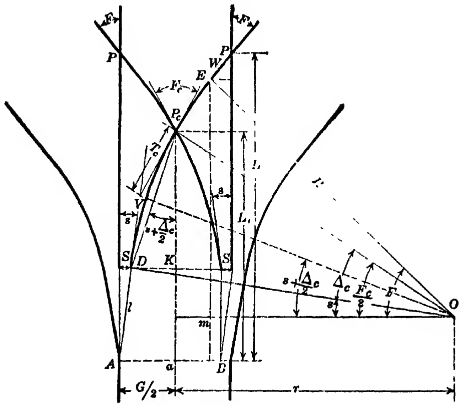

Fig. 18.

Then :—

$$\frac{F_c}{2} = \Delta_c + s; \qquad D\,P_c\,a = V\,O\,m = s + \frac{\Delta_c}{2} = \frac{F_c - \Delta_c}{2};$$

$$\text{Cos}\,\frac{F_c}{2} = \frac{r}{R} = \cos F + \frac{G/2 - W\sin F}{R}; \qquad \cos F = \frac{O\,m}{R};$$

$$N_c = \frac{\cot(F_c/2)}{2};$$

$$T_c = \frac{G/2 - S}{\sin s + \sin(F_c/2)}$$

$$D\,P_c = \frac{G/2 - S}{\sin(s + \Delta_c/2)} = 2\,R\sin\frac{\Delta_c}{2};$$

66. Double (three-throw) turnouts (see ¶¶ 32-4) are also used in connection with ladders.

In such cases, resort may be had to graphic methods.

See also ¶ 73, Yards and Stations, p 1005.

Turnout from Curv. (Point Switch).

67. Computing vs. drafting. Exact equations, for the dimensions of point-switch turnouts from curvs, would be very complicated; and problems, involving such dimensions, are best solvd by means of drawings to liberal scale. The subject is discust mathematically, in "Track Formulæ and Tables", by S. S. Roberts; New York, John Wiley & Sons.

68. Sharpness Difference. In general, and for practical purposes (even with straight switch-rails and frog-rails), the sharpness *diff*, betw the main and turnout curvs, for a given frog-number, may be taken as equal to that of a turnout from straight track, with the same frog number, as in ¶ 26.

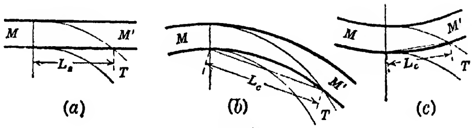

Fig. 22.

69. Lead. Figs 22. For a given frog number, the lead may be taken as approximately equal to that figured for a turnout from a tangent, by eq 10; but, in his Notes on Track, p 373, Mr. W. M. Camp gives the following:—

Let L_s = lead for turnout from tangent, Fig (*a*);
L_c = lead for turnout from curvd track with same frog, Figs (*b*), (*c*).
D = main line curv sharpness; N = frog number.

Then

$$L_c = L_s \pm D\,(N/12)^2 \;\ldots\ldots\ldots\ldots (57)$$

plus when turnout leavs *inside* of curv (Fig *b*), and *vice versa* (Fig *c*). This givs results as follows when $D = 3°$:—

	Lead		
N	L_s	L_c	
	Fig *a*	Fig *b*	Fig *c*
4	37.05	37.38	36.72
12	97.25	100.25	94.25

CURVS

SIMPLE CURVS

GENERAL

Definitions

(For equations, see ¶ ¶ 25, etc)

1. Fig 4a. A railroad line, *a b c . . . f,* is usually an alternation of curvs, *b c, d e,* etc; and of straight lines, *a b, c d,* etc, which are commonly called "tangents" because they are necessarily tangential to the curvs.

Fig 1. In a circular or simple railroad curv, the center line, *A P B* of the track (or, if not level, its projection on a horizontal plane) is a circular arc.

Fig 1. Imagin the tangents, *X A* and *B Z,* at the ends of the curv, *A B,* produced to their intersection, *V.* Then the equal dists, *A V, V B,* are called the **semitangents.**

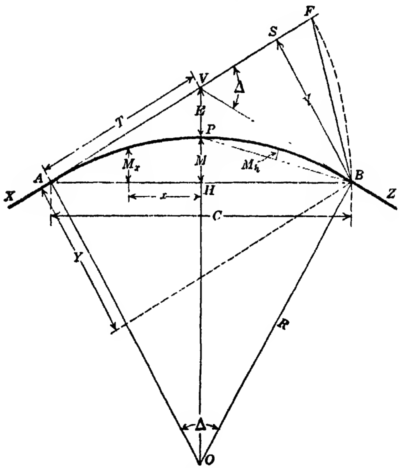

Fig. 1.

2. For the points of change from tangent to curv, etc, etc, we use the symbols adopted by the **Am Ry Eng Assn,** Manual of Recommended Practice, 1915, p 135, as follows:—

For circular curvs	Hitherto called
T. C. From tangent to curv;	Point of curv, P. C.
C. T. " curv " tangent;	Point of tangent, P. T.
C. C. " curv " curv;	Point of compound or of reverst curv, P. C. C. or P. R. C.

For spiral curvs See p 968, ¶ 201.

The point of curv, Fig 1, T. C., is the beginning, *A*, of the curv, or that end of it which is first reacht by the location in its progress.

The point of tangent, C. T., is the other end, *B*, of the curv.

The vertex, point of intersection, P. I., or apex, is the point, *V*, where the two tangents, produced, *A V* and *V B*, meet.

LOCATION.

Curv Functions and their Symbols

3. Fig 1. List of the functions of an entire curv. For that portion of a curv subtended by a unit chain, see ¶ 9.

Functions	Symbols				
Sweep (central angle, see ¶ 10)	Δ	=	$A\,O\,B$	=	$F\,V\,B$
Radius	R	=	$O\,A$	=	$O\,B$
Long Chord	C	=	$A\,B$		
Semitangent	T	=	$A\,V$	=	$V\,B$
External distance	E	=	$P\,V$		
Tangent offset, (perp to tangent $A\,V$ or $B\,V$)	Y	=	$B\,S$		
Tangent distance (making $A\,F = A\,B$)......		=	$B\,F$		
Middle ordinate	M	=	$H\,P$		
Side ordinate, distant x from M	M_x				
Middle ordinate for $\Delta/2$	M_h				

4. Locating points on Curvs. Fig 2. Where the radius *R*, is very short, it is sometimes practicable to locate the center, *O*, of the curv, and to describe the center line on the ground, using a steel tape for the radius; but, ordinarily, the center is not located, and points, *a*, *b*, etc, in the curv, are located by setting the transit at a known point in the curv (as the T. C., at *A*), laying off known peripheral angles, *v A a*, *v A b*, etc, from the tangent, *A v*, and measuring chords, *A a*, *a b*, *b c*, etc, of the proper calculated lengths.

5. Chords and Chains.* In practice, these chords (except the first and last, see ¶ 24) are of equal length, equal (or nearly equal, see ¶ 20) to that of the tape (usually 100 ft or 20 meters long) used in the location of the line, and are called "chains,"* in order to distinguish them from other chords, as *A b*, *b d*, etc, which may be drawn to the curv.

6. The equal peripheral angles, *a A b*, *b A c*, etc, subtended by these equal chains, are called **deflection angles.** Each is equal to $D/2$ = half the corresponding **central angle,** *a O b*, *b O c*, etc.

7. Tangential, Deflection and Central Angles. Samuel W. Mifflin, "Methods of Location for Railway Engineers", 1837, called the angle, *e c d* (= *c O g* = $D/2$), the "*tangential angle*", as being the angle betw a chain,* *c d*, and the *tangent*, *c e*, at its either end. In this, Mifflin followed Col. Stephen H. Long, U. S. A. ("Railroad Manual", 1829), who gave the name, "*deflection angle*", to the angle, *f c d*, betw a chain, *c d*, and the extension, *c f*, of a consecutive chain, *b c*; it being equal to the angle, *e h d* (betw the tangents, *c e* and *h d*, at the two ends of a chain, *c d*), thru which *the line deflects* within the dist subtended by a chain. It is equal to the *central* angle, *D* = *c O d*, subtended by a chain, *c d*.

8. We, in "The Field Practice of Laying out Circular Curvs for Railroads" (first edition, 1851), and Mr. William Findlay Shunk, in "The Field Engineer", 1880, followed this nomenclature. Now, however, usage calls *e c d* the **"deflection angle"** or simply the "deflection" (as indicating a deflection of the line of sight) and calls *D* (= *f c d*) the **"degree of curv".** See Sharpness, ¶ 11.

---

*The use of the word "chain", to designate such a chord, survives from the days when survey *tapes* were unknown, and when the measuring was done by means of chains made up of wire links. The standard full *length* of such a chain was called "one chain."

9. Figs 1 and 2. In that portion of a curv, as *a b*, Fig 2, subtended by a unit chain*, *c*, we have sweep, $\Delta = D$, and we designate the several other functions by "lower-case" instead of by capital letters. Thus;

the letters .... *C T E Y M* M_x and M_h, Fig 1, ¶ 3,
become, respectivly .. *c t e y m* m_x and m_h, in the arc *a b*, Fig 2.

10. Fig 1. The sweep, Δ, of the curv, is the angle, *A O B*, swept out by the radius, *R*, and subtended by the curv. It is also the angle, *F V B*, swept out by the tangent in swinging from *V F* to *V B*. It is therefore the total deflection of the line, due to the curv; or it is the intersection angle betw the two tangents. Each *portion* of the curv of course has also its own sweep.

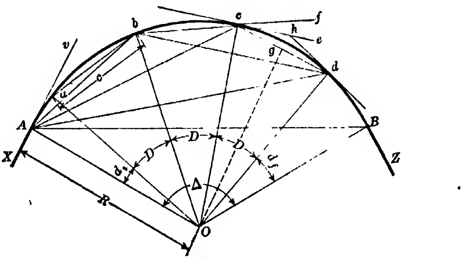

Fig. 2.

11. Fig 2. The sharpness, (commonly called the **"degree of curvature"**) is usually exprest by the sweep or *central* angle, *D*, (= *a O b* = *b O c*, etc) subtended by a *chain**, *a b* or *b c*; *i. e.*, sharpness = the deflection, *e h d*, of the line, in a length of one chain. A "one-degree", "two-degree", "three-degree-thirty-minute", etc curv is one whose sharpness is 1°, 2°, 3°30′, etc. See ¶ 14.

12. Fig 2. But sometimes (especially where the metric system is used) the curv is named for its *peripheral* chain angle, *c b d* = *c A d*, etc, or angle subtended at the *circumference*, as at *b* or *A*. A given curv, called
1° 00′, 2°, 3° 30′, etc, after its *central* chain angle, would be called 0° 30′, 1°, 1° 45′, etc, after its *peripheral* chain angle.
We follow the definition of ¶ 11.

13. Fig 3. When curvs are located by means of short chains* (see ¶ 19), the sharpness is sometimes taken as the sweep subtended by a *series* of such chains, the *sum* of whose lengths is equal to the standard unit chain. Thus, a curv, *a p b*, in which a series of two chains, *a p*, *p b*, of 50 ft each, subtends an angle of *D*°, is then called a *D*° curv, altho it is sharper (has a shorter radius, R_2 = *O b*) than the *D*° curv, *A P B* (R_1 = *O B*), in which the same angle of *D*° is subtended by a single chain, *A B*, of 100 ft.

14. Fig 1. In countries other than the U. S., the sharpnesses of curvs are often designated by the lengths of their *radii*, *R* = *O A* = *O B*, etc. The greater the sharpness, the shorter is the radius.

15. Graphic representation of curvature. In Fig 4, the center line, *a f* (Figs *a* and *b*) and the rectangles (Fig *b*) below and above it, represent the supposititious case tabulated below.

---

*The use of the word "chain," to designate such a chord, survives from the days when survey *tapes* were unknown, and when the measuring was done by means of chains made up of wire links. The standard full *length* of such a chain was called "one chain."

Since the abscissas, *a b*, *a c*, etc, Fig *b*, represent dists along the line, while the ordinates represent sharpness of curvature, the *areas* of the rectangles represent the *sweeps* of the curvs, or the deflections of the tangents from each other. Similarly with *portions* of the rectangles; thus, the area of the rectangle on *b′ c* represents the sweep of the portion, *b′ c*, of the simple curv, *b c*.

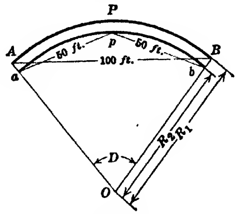

Fig. 3.

16. The inclined lines (Fig 4 *b*) represent easements of the ends of the curvs by means of spirals (see p 966). Since the positions of the tangents are not changed by the introduction of the spirals, the sweeps of the curvs, and the areas representing them, remain unchanged also. Thus, area of trapezoid on *B C* = area of rectangle on *b c*.

Chains*. Curv Length

17. The unit of railroad and of curv measurement is usually either 100 feet or 20 meters (= say 65.617 ft).

18. Full chain*. It is usual to make this (100 ft, or 20 meters) the *chain* length; and the **length of the curv** is then stated (*approximately*) as being equal to the sum of the *chain* lengths used in locating it. Thus, Fig. 6, in the curv, $A\ a\ b\ c\ B$, the length is taken as being $= A\,a + a\,b + b\,c + c\,B$, measured along these *chords*, $= 43 + 200 + 36.7 = 279.7$ ft The *true* length of the curv is of course slightly *greater* than this. See p 902.

19. Short chain.* Sharp curvs are usually located by means of a short chain whose length is half or quarter that of the standard chain, or less; these short chains subtending correspondingly smaller central angles. Thus, where the standard chain is 100 feet, chains (tape lengths) of 50 or 25 ft or less are used on such curvs. In general, the chain length used is not greater than from one-twelfth to one-eighth of the radius of the curv. The sum of a series of such short chain-lengths, subtending a given arc, is evidently greater (more nearly equal to the length of the arc itself) than is the sum of standard unit chain-lengths subtending the same arc. See ¶ 13.

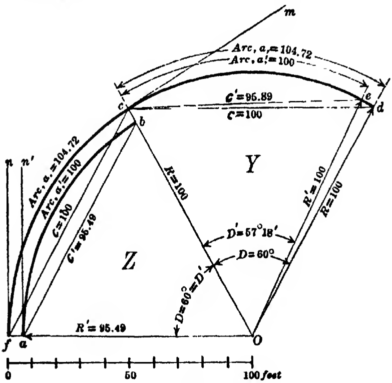

Fig. 5.

20. Diminisht chains*. If, on curvs, the rear chainman holds the tape with a properly calculated small reading (instead of the zero mark) at the stake, thus slightly diminishing the effectiv unit "chain" length, the *arc* subtended is thereby reduced to the full unit length, the *stated* length of the curv is made to correspond with its *actual* (curvd) length, and certain formulas (¶ 42) for finding curv functions (otherwise only approx) are renderd exact.

21. Sharpness, as affected by the use of diminisht chains*. Fig 5 Y. In the curv, $c\ e\ d$, let the full "chain", $c = c\,d = 100$ ft,

*The use of the word "chain," to designate such a chord, survives from the days when survey *tapes* were unknown, and when the measuring was done by means of chains made up of wire links. The standard full *length* of such a chain was called "one chain."

subtend a central angle, $D = c\,O\,d = 60°$. Then $c\,e\,d$ is a 60° curv, and its deflection angle, $D/2 = m\,c\,d = 30°$. To run **the same curv** with a *diminisht* chain, $c' = c\,e$ ($= 95.89$ ft, ¶ 22) we must use a deflection angle, $m\,c\,e$, of only 28° 39′, and D', ($= c\,O\,e$) $= 57°\,18'$. Thus, the use of diminisht chains makes a given curv *nominally flatter*.

22. Fig 5 *Z*. If, with diminisht chain, $c' = a\,b$, we use **the same deflection angle,** ($n'\,a\,b = n\,f\,c$), as with the full chain. ($c = f\,c$), we shall obtain a sharper curv, $a\,b$ (radius $= O\,a$) than with the full chain, which would give the curv $f\,c$, (radius $= O\,f$). Thus, the use of the diminisht chain makes a nominally equal curv *actually sharper*.

In Figs 5 *Y* and 5 *Z*, the functions compare as follows:

($Q = a/c$ or a'/c')

Fig	R, ft	R', ft	D	D'	a, ft	a', ft	c, ft	c', ft	Q
5 *Y*	100.00		60° 00′		104.72		100.00		1.047
		100.00		57° 18′		100.00		95.89	1.043
5 *Z*	100.00		60° 00′		104.72		100.00		1.047
		95.49		60° 00′		100.00		95.49	1.047

23. Stations. As on the tangents, the end-points of chains, on curvs, are called "stations"; but the name, "station", is often (loosely) applied to *the distance between* two such points.

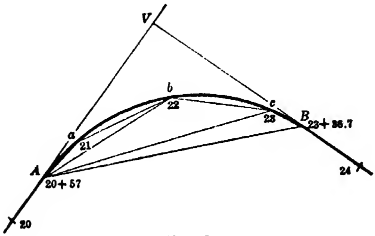

Fig. 6.

24. "Plus" stations; Sub-chains. Fig. 6. It can only accidentally happen that a curv begins or ends exactly at a station of the location. In other words, the T. C. and the C. T. nearly always fall *between* stas, *i. e.*, at a "plus" sta, as at sta A = 20 + 57, or at station B = 23 + 36.7; and this necessitates the use of a sub-chain, $A\,a$ or $c\,B$, and a sub-angle, $V\,A\,a$ or $V\,B\,c$ ($V\,B\,c = c\,A\,B$), at one or at both ends of the curv. See ¶¶ 44, etc.

GEOMETRY

Propositions of frequent application

25. Fig 7. **Similar triangles, and ratios between chord segments.** Let OV be a diam of the circle, $AVBO$; let AB ($= C$) be a chord perpendicular to OV and bisected at H; let OA, AV be chords in the semi-circle, OAV; and OB, BV, chords in the semi-circle, OBV; let AV ($= VB$) $=$ semitangent, T; and OA ($= OB$) $=$ radius, R, of the curv, APB.

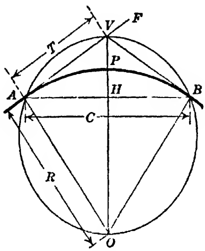

Fig. 7.

Then the 3 right triangles, OHA, AHV and OAV are similar; as are also OHB, BHV and OBV; angle, OAV ($= OBV$), betw R and T, $= 90°$; $AH = HB = C/2$; and

From similar triangles	We have		
OHB, BHV;	$OH : HB = HB : HV$;		
	$OH \times HV = (C/2)^2$;	or	$HV = (C/2)^2 \div OH$ (1)
OBV, BHV;	$OV : VB = VB : HV$;		
	$OV \times HV = T^2$;	or	$HV = T^2/OV$ ......(2)
OBV, OHB;	$OV : OB = OB : OH$;		
	$OV \times OH = R^2$;	or	$OH = R^2/OV$ ....(3)

26. Fig 8. **Angles between two chords, between two tangents, and between a chord and a tangent. Values of $\Delta/2$.** Let APB be the arc, and AB the chord, subtending the central angle, $AOB = \Delta = FVB = AOd + dOB = AOe + eOB$

Then

$\Delta/2$ = angle betw the tan, AV, at A, (or tan VB, at B) and the chord, AB

= external angle betw any two chords, as Ad and dB, or Ae and eB, drawn to the arc from A and from B respectively

= $(AOd + dOB) / 2 = (AOe + eOB) / 2$

= the peripheral angle, $AEB = VAB = VBA$, subtended by the chord, AB. ....(4)

27. Small angles, (such as the deflections usual in steam railroad work), are **approx proportional to their sines,** and less nearly proportional to their tangents. This fact may be used to facilitate many calculations.

Thus, for any small angle, A, we have,

approx: $\sin 0° 1' : \sin A = 1 \text{ minute} : A$, in mins; or

$A \text{ mins} = \sin A \div \sin 0° 1' = 3437 \sin A$;

$\sin A = A \text{ mins} \times \sin 0° 1' = 0.0002909\ A \text{ mins}$. . (5)

Similarly (approx) $\tan A = A \text{ mins} \times \tan 0° 1' = 0.0002909\ A$ mins.

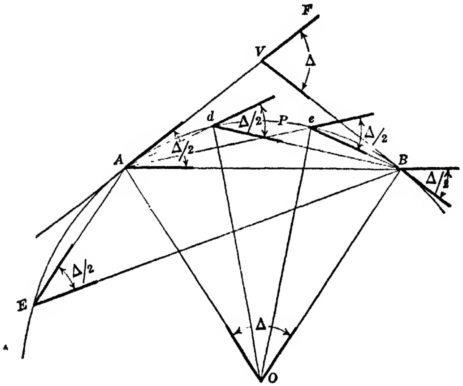

Fig. 8.

Example. With 100 ft chain; given radius, R, = 1300 ft; required the sharpness, D, of the curv. Here, $\sin (D/2) = 50/1300$; and $D = 4° 24' 30.44''$.

Approx, $D/2$ in mins

$= \sin (D/2) \div \sin 0° 1'$

$$= \frac{50}{1300} \times \frac{1}{\sin 0° 1'} = 132.221.$$

Hence, D approx $= 264.442$ mins $= D - 0.065$ min $= 0.99975\ D$.

Conversely; given $D = 4° 24'$, required the radius, R. Here

$$R = \frac{50}{\sin(D/2)} = 1302.497 \text{ ft.}$$

$$R \text{ approx} = \frac{50}{(D/2) \text{ in mins} \times \sin 0° 1'}$$

$$= 1302.177 \text{ ft} = 0.99975\ R.$$

Such operations are conveniently performd with the **slide-rule,** pp 73 etc.

Errors of Approximation.

Let A be in minutes; and let

$$S = \frac{A \sin 0^\circ 1'}{\sin A}; \qquad T = \frac{A \tan 0^\circ 1'}{\tan A}. \text{ Then:—}$$

for $A =$	$S =$	$T =$	for $A =$	$S =$	$T =$
0° 30′	1.000013	0.999995	6° 0′	1.001830	0.996342
1° 0′	1.000051	0.999898	7° 0′	1.002492	0.995020
2° 0′	1.000203	0.999594	8° 0′	1.003257	0.993493
3° 0′	1.000457	0.999086	10° 0′	1.005095	0.989825
4° 0′	1.000813	0.998375	20° 0′	1.020600	0.959050
5° 0′	1.001270	0.997460			

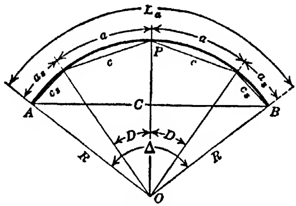

Fig. 9.

28. Relations between Δ, D, n, R, L_a and L_c. Fig 9.
In any circular curv, let

R = radius; $\pi = \dfrac{\text{circumf}}{\text{diam}}$; Δ = sweep; C = long chord;

L_a = curv length, $A\,P\,B$, measured on the arc. Then:—

πR = semi-circumf (subtending 180°);

$\dfrac{\pi R}{180}$ = arc subtending 1°; and (Δ in *degrees*)

$$L_a = \Delta \frac{\pi R}{180}; \quad \Delta = \frac{180\, L_a}{\pi R}; \quad \text{and} \quad R = \frac{180\, L_a}{\pi \Delta} \ldots. (6)$$

Let c = chain length, in ft; a = unit arc, in ft; n = number of chains, c, or of unit arcs, a, in the curv*; D = sharpness; L_c = curv length, $A\,P\,B$, measured on chains, = sum of lengths of chains. L_a = true curv length. Then:—

*Usually n is a mixt number. Thus, with two chains of 100 ft each, and sub-chains of 33.6 ft and 21.8 ft respectively, we have $n = 2 + 0.336 + 0.218 = 2.554$.

With *full* chain, ¶ 18	With *diminisht* chain, ¶ 20
$\sin\dfrac{D}{2} = \dfrac{c/2}{R}$ ....(7)	$D^\circ = \dfrac{180\,a}{\pi\,R}$ ....(11)
$\Delta = n\,D$ ....(8)	$\Delta = n\,D$ ....(12)
$R = \dfrac{c/2}{\sin(D/2)}$	$R = \dfrac{180\,L_a}{\pi\,\Delta^\circ} = \dfrac{180\,a}{\pi\,D^\circ}$ ..(13)
$= \dfrac{c}{2\sin(D/2)}$ ....(9)	
$L_c = n\,c;$ $n = L_c/c = \Delta/D$ ...(10)	$L_a = n\,a;$ $n = L_a/a = \Delta/D$ ...(14)

29. Hence, for the radius, R_f, in feet, or R_m, in meters, we have:—

	On any curv		On a 1° curv	
	Curv measured by			
¶ 18	100-ft chain	20-meter chain	100-ft chain	20-meter chain
	Radius			
	$R_f =$	$R_m =$	$R_f =$	$R_m =$
With full chain,	$\dfrac{50\text{ ft}}{\sin(D/2)}$	$\dfrac{10\text{ m}}{\sin(D/2)}$	$\dfrac{50\text{ ft}}{\sin 0^\circ\,30'}$ = 5729.650 ft log = 3.758 1281	$\dfrac{10\text{ m}}{\sin 0^\circ\,30'}$ = 1145.930 m log = 3.059 1581
	Curv measured by			
¶ 20	100-ft arc	20-meter arc	100-ft arc	20-meter arc
	Radius			
	$R_f =$	$R_m =$	$R_f =$	$R_m =$
With diminisht chain,	$\dfrac{18{,}000\text{ ft}}{\pi\,D}$	$\dfrac{3{,}600\text{ m}}{\pi\,D}$	$\dfrac{18{,}000\text{ ft}}{\pi}$ = 5729.578 ft log = 3.758 1226	$\dfrac{3600\text{ m}}{\pi}$ = 1145.916 m log = 3.059 1526

General Curv Equations

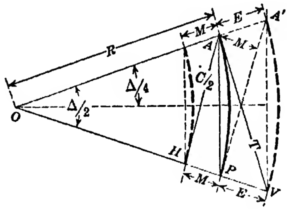
For symbols, see ¶¶ 3 and 9, pp 875, 876.

30. Fig 10. To avoid undue repetition, one equation is here frequently intended to serv, by inversion and substitution, for all the factors involvd and for others. Thus, from

$M = R \text{ vers}(\Delta/2)$, we have, also:—

$$R = M/\text{vers}(\Delta/2)\,; \quad \text{vers}\frac{\Delta}{2} = \frac{M}{R} = \frac{E\cos(\Delta/2)}{T\cot(\Delta/2)}\,;$$

etc, etc. See ¶ 69.



$$\frac{\Delta}{2} = HAV; \ \frac{\Delta}{4} = HAP = PAV = AVA'.$$

Fig. 10.

Angular Functions

31. Fig 10. **Functions of $\Delta/2$.**

$$\text{Sin}\frac{\Delta}{2} = \frac{C}{2R} = \frac{T}{R+E} = \frac{E+M}{T} \quad \text{.......... (17)}$$

$$\text{Cos}\frac{\Delta}{2} = \frac{R-M}{R} = \frac{M}{E} = \frac{R}{R+E}$$

$$= \frac{T^2-E^2}{T^2+E^2} = \frac{C^2-4M^2}{C^2+4M^2} \quad \text{.......... (18)}$$

$$\text{Tan}\frac{\Delta}{2} = \frac{T}{R} = \frac{E+M}{C/2} = \frac{C/2}{R-M} \quad \text{.......... (19)}$$

$$\text{Vers}\frac{\Delta}{2} = 1 - \cos\frac{\Delta}{2} = \frac{M}{R} = \frac{E}{R+E}$$

$$= \sin\frac{\Delta}{2} \times \tan\frac{\Delta}{4} = 2\sin^2\frac{\Delta}{4} \quad \text{.......... (20)}$$

$$\text{Exsec}\frac{\Delta}{2} = \frac{E}{R} = \frac{E-M}{M}\,; \quad \text{.......... (21)}$$

32. Fig 10. **Functions of $\Delta/4$.**

$$\sin\frac{\Delta}{4} = \frac{PH}{AP} = \frac{M}{\sqrt{M^2 + (C/2)^2}} = \frac{\sqrt{M^2 + (C/2)^2}}{2\,R};$$

$$\sin^2\frac{\Delta}{4} = \frac{AP}{2R}\,\frac{PH}{AP} = \frac{M}{2R} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots (22)$$

$$\tan\frac{\Delta}{4} = \frac{E}{T} = \frac{2M}{C} = \sqrt{\frac{2T - C}{2T + C}} = \sqrt{\frac{E - M}{E + M}} = \frac{\operatorname{vers}(\Delta/2)}{\sin(\Delta/2)}$$

which may be shown to be

$$= \frac{T}{2R + E} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (23)$$

Linear functions

33. Fig 10. Relations between R, E and M.

$$R + E = \sqrt{T^2 + R^2} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (24)$$

$$R - M = \sqrt{R^2 - (C/2)^2} = \sqrt{(R + C/2)\ (R - C/2)} \ldots (25)$$

$$E + M = \sqrt{T^2 - (C/2)^2} = \sqrt{(T + C/2)\ (T - C/2)} \ldots (26)$$

34. Fig 11. Equations for R, C, T, E, Y, BF, M and M_1.
D = sharpness, *in degrees* unless otherwise stated.

$$R^* = \frac{T}{\tan(\Delta/2)} = \frac{C}{2\sin(\Delta/2)} = \frac{M}{\operatorname{vers}(\Delta/2)} = \frac{E}{\operatorname{exsec}(\Delta/2)}$$

$$= \frac{T^2 - E^2}{2E} = \frac{(C/2)^2 + M^2}{2M} = \frac{EM}{E - M};$$

$= \text{approx } R_1/D = (R \text{ for } 1° \text{ curv})/D = \text{approx } 5729.65 \text{ ft}/D$
$= \text{approx } C^2/8M$ (see table, p 893) ……………………… (27)

$$C = 2R\sin(\Delta/2) = 2T\cos(\Delta/2)$$

$$= 2M\cot(\Delta/4) = 2\sqrt{M\,(2R - M)}$$

$$= 100\,\frac{\sin(n\,D/2)^*}{\sin(D/2)}$$

$$= 2E\,\frac{\sin(\Delta/2)}{\operatorname{exsec}(\Delta/2)} = \text{approx } \sqrt{8\,R\,M} \text{ (see table, p 893)} \ldots (28)$$

$$T = R\tan(\Delta/2) = \frac{C}{2\cos(\Delta/2)}$$

$$= M\,\frac{\tan(\Delta/2)}{\operatorname{vers}(\Delta/2)} = E\cot(\Delta/4)$$

$$= (R + E)\sin(\Delta/2) = \sqrt{E\,(2R + E)}$$

$$= \sqrt{(C/2)^2 + (M + E)^2} = \frac{M + E}{\sin(\Delta/2)} \quad \ldots\ldots\ldots\ldots (29)$$

$$E = R \operatorname{exsec}(\Delta/2) = T \tan(\Delta/4) = M \sec(\Delta/2)$$
$$= R \tan(\Delta/2) \tan(\Delta/4) = C \frac{\operatorname{exsec}(\Delta/2)}{2 \sin(\Delta/2)} = \frac{R\ M}{R - M}$$
$= \text{approx } M$ (see table, p 893) .... (30)

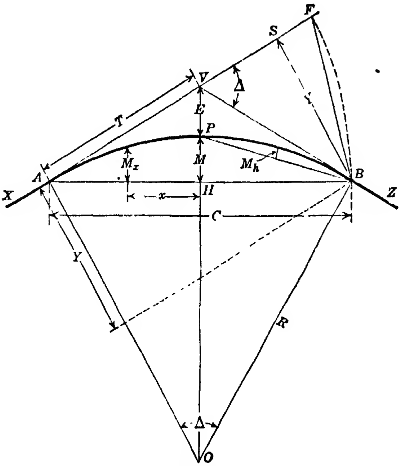


Fig. 11.

$$Y = R \operatorname{vers} \Delta = C \sin(\Delta/2)$$
$$= 2\,R \sin^2(\Delta/2) = C^2/2\,R = T \sin \Delta$$
$$= E \frac{\operatorname{vers} \Delta}{\operatorname{exsec}(\Delta/2)} = M \frac{\operatorname{vers} \Delta}{\operatorname{vers}(\Delta/2)}$$
$= \text{approx}$ (see table, p 893) $4\,M = \frac{7}{8} n^2 D^\circ$ * .... (31)

$BF = 2\,C \sin(\Delta/4)$ .... (31a)

$$M = R \operatorname{vers}(\Delta/2) = 2\,R \sin^2(\Delta/4) = \frac{PB^2}{2\,R} = T \frac{\operatorname{vers}(\Delta/2)}{\tan(\Delta/2)}$$
$$= (C/2) \tan(\Delta/4) = E \cos(\Delta/2) = R\,E/(R + E)$$
$$= R - \sqrt{R^2 - (C/2)^2} = R - \sqrt{(R + C/2)\ (R - C/2)}$$
$$= R \sin(\Delta/2) \times \tan(\Delta/4);$$
$= \text{approx}$ (see table, p 893) $4\,M_h = Y/4 = B\,F/4$
$= \frac{M + E}{2} = E = \frac{C^2}{8\,R} = \frac{7}{32} n^2 D^\circ$* .... (32)

$$M_h = R \operatorname{vers}(\Delta/4) = M \frac{1 - \cos(\Delta/4)}{1 - \cos(\Delta/2)} = M \frac{\sin^2(\Delta/8)}{\sin^2(\Delta/4)}$$

$$= \text{approx } \frac{M}{4} \text{ (see table, below)} \ldots\ldots\ldots\ldots\ldots\ldots\ldots (33)$$

For side ordinate, M_x, see ¶ 35.

Multipliers for Converting Approximate Values from Equations Above **to Correct Values.** The following table of multipliers indicates the degrees of approximation of our several approximate equations in ¶ 34, and enables us to obtain the correct values from them.

Example. Given $\Delta = 30°$; required the middle ordinate, M, for the entire curv. Here eq (32) gives, approx, $M = BF/4$; but, in the following table, in the line beginning "(32) $M = BF/4$", and in the colum headed "$\Delta = 30°$", we find the correctiv multiplier, 1.0088, which gives the true value, $M = 1.0088 \times BF/4 = 0.2522\,BF$.

Eq No.	Equation.	$\Delta =$ 1°	10°	20°	30°	60°	90°
		To obtain correct values of the equations, multiply the approx value by the proper coefficient given below					
(32)	$M = 4\,M_h$	1.0000	0.9995	0 9981	0.9957	0.9830	0.9619
(33)	$M_h = M/4$	1.0000	1.0005	1.0020	1.0043	1.0173	1.0396
(31)	$Y = 4\,M$	1.0000	0.9980	0.9925	0.9831	0.9328	0.8535

	for $D = 1°$	0.9974	0.9949	0.9873	0.9747	0.9095	0.8085
	" $D = 10°$	0.9986	0.9961	0.9885	0.9760	0.9106	0.8095
	" $D = 20°$	1.0024	0.9999	0.9922	0.9798	0.9141	0.8126
(27)	$R = R_1/D°$						
When		$D=5°$	$D=10°$	$D=15°$	$D=20°$	$D=30°$	$D=40°$
Mult R_1/D by		1.0003	1.0013	1.0028	1.0051	1.0115	1.0206

*n = number of unit chains in the curv.

Long Chords, C, in ft, required to subtend from two to eight 100-ft chains, for different sharpnesses, *D*.

$$C = 2R \sin(\Delta/2)$$

For table of long-chords to a 1° curv, for diff sweeps, Δ, see ¶ 40*a*.

35. Side ordinate, M_x. Fig 12.

$$M_x = \sqrt{R^2 - x^2} + M - R = \sqrt{R^2 - x^2} - R\cos(\Delta/2) \quad \ldots (34)$$

$$= \text{approx } a\,b/2\,R \text{ (see table, below)} \quad \ldots (35)$$

where a and b are the two segments of the chord, C,

$$= \text{approx } 4\,M\,a\,b/C^2 \text{ (see table, below)} \quad \ldots (36)$$

When $C = 100$ ft ($= c$; $\Delta = D$), eq (36) becomes:—

$$m_x = \text{approx } \frac{m\,a\,b}{2500} = \text{approx } \frac{m}{0.25} \cdot \frac{a}{100} \cdot \frac{b}{100} \quad \ldots (37)$$

or, since in that case, $B\,F$ (= "tangntl dist") $= 200\sin(D/4)$ = approx $4\,m$, we have, for any curv and for any value of C:—

$$M_x = \text{approx } B\,F \cdot \frac{a}{100} \cdot \frac{b}{100} = \frac{B\,F \cdot a \cdot b}{10{,}000} \quad \ldots (38)$$

See table p 893, using coeffs for $R = C^2/8\,M$. Thus, for $\Delta = 60°$, $M_x = 1.0718\ B\ F \cdot a \cdot b/10{,}000$.

$$M_x = \text{approx } D \times M_1 \text{ (see table, below)} \quad \ldots (39)$$

where D = the sharpness of the given curv, and M_1 = the side ord for a 1° curv, at the given dist, x, from its mid ord, M, on an equal chord, C.

Coefficients for the foregoing approximate equations for side ordinates, M_x.

The following table of multipliers indicates the degree of approximation of our several approximate equations in ¶ 35, and enables us to obtain the correct values from them.

Example. Given $\Delta = 20°$, and $x/C = 1/4$; required the ordinate, M_x, dist x from the mid ord, M. Here eq (35) gives, approx, $M_x = a\,b/2\,R$; but, in the following table, in the line beginning "(35) $M_x = a\,b/2\,R$", and in the column headed "$\Delta = 20°$, $x/C = 1/4$," we find the correctiv multiplier, 1.0096, which gives the true value, $M_x = 1.0096\,a\,b/2\,R = 0.5048\,a\,b/R$.

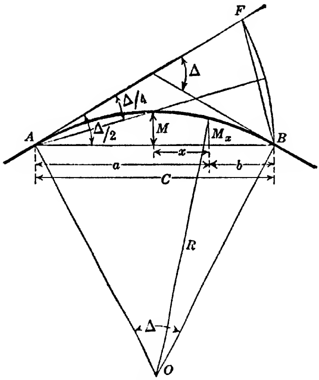

Fig. 12.

Eq. No	Equation.	Δ = 10° x/C =			Δ = 20° x/C =		
		1/4	3/8	19/40	1/4	3/8	19/40
(35)	$M_x = ab/2R$	1.0024	1.0028	1.0024	1.0096	1.0128	1.0094
(36) (37)	$M_x = 4\,Mab/C^2$ $m_x = mab/2500$	1.0005	1.0011	1.0012	1.0019	1.0051	1.0076

36. For that portion of a curv which is subtended by a **chain, c, or unit arc, a,** (sweep, Δ, = sharpness, D), use the equations of ¶ ¶ 34, 35,

substituting D, t, c, m, m_x, e, y and m_h
for Δ, T, C, M, M_x, E, Y and M_h respectivly.

Middle Ordinates, m, in ft, to 100-ft chain, **for different sharpnesses,** *D.*

37. Ratio, Q, of arc to chord. Fig. 9. In any circular curv, of radius R, and sweep Δ, we have (see ¶ 28) :—

$$\text{Eq (6) length, } L_a \text{, of arc, } = \frac{\pi R}{180} . \Delta^\circ \text{; and}$$

$$\text{Eq (28) long chord, } C, = 2 R \sin(\Delta/2).$$

Hence, for the ratio, Q, betw arc, L_a, and chord, C, we have :—

$$Q = \frac{L_a}{C} = \frac{\pi}{360} . \frac{\Delta^\circ}{\sin(\Delta/2)} ; \quad \ldots\ldots\ldots\ldots (40)$$

where π = 3.14159 . . . ;
$\pi/360$ = 0.008 726 647 ;
$360/\pi$ = 114.5916 ;
log π = 0.497 1499
log $(\pi/360)$ = 7.940 8474 :
log $(360/\pi)$ = 2.059 1526.

Hence Q is a function of Δ.

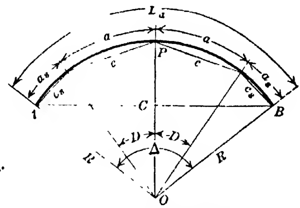

Fig. 9. (Repeated)

Values of Q = $\frac{\text{arc}}{\text{chord}}$.

Note that $Q - 1$ increases a little faster than Δ^2.

38. Fig 5 Y. Value of Q (= arc/chord) in the case of the unit chain, c, or unit arc, a' (where sweep, Δ, = sharpness, D or D'.)

Let
D° = central angle subtended by unit chain, c, and by the corresponding arc, a;
D'° = central angle subtended by unit arc, a', and by the corresponding chord, c'.

Then, from eq (40), we have, by substitution :—

$$Q = \frac{a}{c} = \frac{\pi}{360} \times \frac{D^\circ}{\sin(D/2)}$$

$$= \frac{a'}{c'} = \frac{\pi}{360} \times \frac{D'^\circ}{\sin(D'/2)} \quad \ldots\ldots\ldots\ldots (41)$$

39. Approximately :—

$$C = La\left(1 - \frac{La^2}{24\,R^2}\right); \text{ and } c = a\left(1 - \frac{a^2}{24\,R^2}\right) \quad ..(42)$$

(See Rankine, Civil Engng, p 104) When $\Delta = 50°$, this makes C only 0.031 per cent too short.

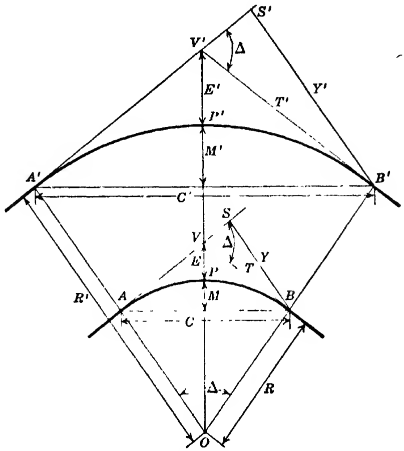

Fig. 13.

Comparisons of Curvs.

40. Fig 13 Comparison betw two curvs of **given sweep, Δ.** Ratios betw corresponding **linear functions.** Let F represent a linear function (as the radius, R, the arc, $A\,B$ (A), the semitan, T, etc) of one of two given curvs of equal sweep, Δ, but of different sharpness, D, and let F' represent the corresponding function, (as R', $A'\,B'(A')$, T', etc) of the other curv. Then, from similar triangles, we have :—

$$F/F' = R/R' = C/C' = A/A' = T/T', \text{ etc};$$
$$\text{or } F' = FR'/R = FC'/C, \text{ etc};$$
$$F = F'R/R' = F'C/C', \text{ etc} \quad \ldots\ldots\ldots\ldots(43).$$

Thus, let C be a unit chain of 100 ft, and let $C' = 200$ ft. Then, for instance, $M' = MC'/C = 2\,M$; $R' = 2\,R$; etc;

$$\frac{\sin\,(D'/2)}{\sin\,(D/2)} = \frac{50}{R'}\cdot\frac{R}{50} = \frac{R}{R'}.$$

Note that, with *given sweep*, Δ, the *sharper* curv has the *shorter* linear functions. Compare ¶ 43.

Functions of a 1° Curv.

40a. Figs 1 and 11. Table of Functions, F_1 (Semitangents, T_1; External Distances, E_1; and Long Chords, C_1); to a 1° curv, for different sweeps, Δ.

$T_1 = R_1 \tan(\Delta/2)$; $E_1 = R_1 \operatorname{exsec}(\Delta/2)$; $C_1 = 2 R_1 \sin(\Delta/2)$.

For the corresponding function, F (T, E or C) of a curv **of any other sharpness, D°,** we have approximately

$$F = F_1/D°.$$

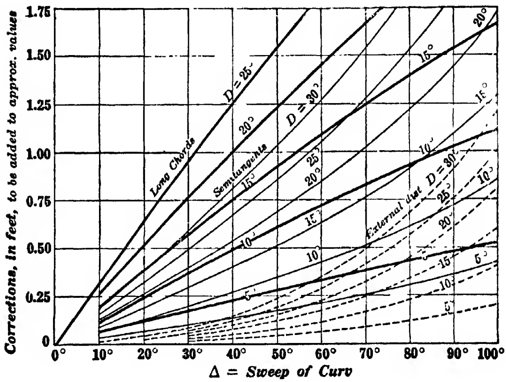

Diagram of Corrections

Corrections, in feet, to be added to approximate curv functions, F (Semitangent, T; External Distance, E; and Long Chord, C) for a $D°$ curv, as found by dividing the corresponding 1° curv function, F_1, of Table, pp 905-908, by D in degrees.

Light solid curvs give values to be added for semitangents, T;
Light dotted curvs give values to be added for external dists, E.
Heavy solid curvs give values to be added for long chords, C.

41. English & Metric. Fig 13. Comparison betw curvs in English and metric (or other) measures. Again, let
$C = c =$ a *chain* of n meters ($\Delta = D$).
$C' = c' =$ a *chain* of 100 feet ($\Delta = D'$).

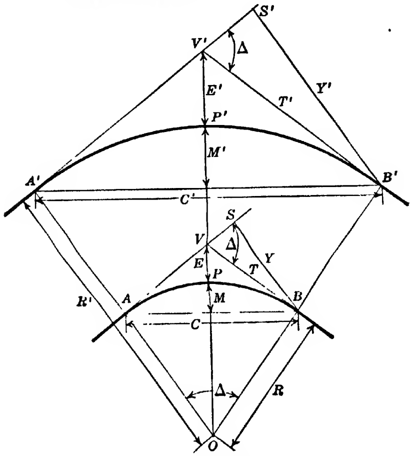

Fig. 13. (Repeated)

Then the two curvs, in Fig 13, altho of diff sharpnesses, are *called* by the same number of degrees; because, in each, the adopted chain subtends the same angle, $D = D'$.

For instance, from eq (43), we have

$$\frac{R \text{ meters}}{R' \text{ feet}} = \frac{c \text{ meters}}{c' \text{ feet}} = \frac{n}{100}\text{ ; and}$$

$$R \text{ meters} = R' \text{ ft } \frac{c \text{ meters}}{c' \text{ feet}} = R' \text{ ft } n/100. \text{ Or, in general :—}$$

$$F = F' c/c' = 0.01\, n\, F' \quad \ldots\ldots\ldots\ldots\ldots (44)$$

Example. Let $\Delta = D = D' = 6°$; $R' = 955.366$ ft. (table, p 886). Then, in a 6° metric curv ($c = 20$ meters; $n = 20$), we have :— R meters $= 0.01 \times 20\, R' = 0.2 \times 955.366 = 191.073$ meters.

Similarly, any table of linear curv functions, in any unit (as in feet, Table p 884), may be used for a curv in any other unit, by multiplying the tabular values by the ratio betw the numbers expressing the chain lengths of the two systems. The results (products) will be in said other unit.

42. Fig 13. **Effect of sharpness, D, upon linear functions** of entire curv of given sweep, Δ. Comparison betw 1° and $D°$ curvs. Ratio betw **exact and approx values.**

Let F_1 (function of 1° curv) = the radius, R_1, or the long chord, C_1, or the semitan, T_1, etc, for a 1° curv, of given sweep, Δ ; and let F_d = the corresponding function of a $D°$ curv of the same sweep, Δ.

Then, where the *"diminisht"* chain (¶ 20) is used, we have,

(D in *degrees*)

$$D = F_1/F_d; \quad F_d = F_1/D; \quad F_1 = D\,F_d \ldots\ldots (45)$$

But, where the *full* chain is used, these equations are only approx. For the ratio, q, betw the true value, F_d, and the approx value, F_1/D, we have: $R_1 = 50/\sin 0°\ 30' = 5729.65$; $\log R_1 = 3.758\,1281$.

$$q\left(= \frac{F_d}{F_1/D} = \frac{R_d}{R_1/D}\right) = \frac{50}{\sin(D/2)} \cdot \frac{D \sin 0°\ 30'}{50}$$

$$= D\,\frac{\sin 0°\ 30'}{\sin(D/2)} \ldots (46)$$

and, since (eq 41, ¶ 38) $Q = \dfrac{a}{c} = \dfrac{\pi}{360} \times \dfrac{D}{\sin(D/2)}$; we have:—

$$\frac{Q}{q} = \frac{\pi}{360} \cdot \frac{D}{\sin(D/2)} \cdot \frac{\sin(D/2)}{D \sin 0°\ 30'}$$

$$= \frac{\pi}{360} \cdot \frac{1}{\sin 0°\ 30'} = 1.000\,013 \ldots\ldots (47)$$

$$\text{Log } (Q/q) = 0.000\,0055.$$

In other words, the value of Q ($=$ arc/chord), in table, ¶ 37, for any given value of Δ, may be taken as practically identical with the value of q [$= F_d/(F_1/D)$], for the same value of D.

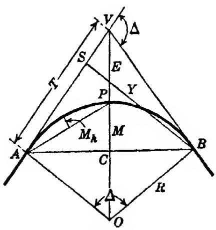

Fig. 14a.

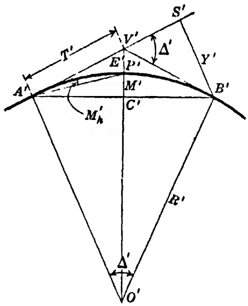

Fig. 14b.

43. Figs 14*a*, 14*b*. As between two curvs of **equal length,** L_a or L_c, the sharper (Fig 14*a*) of course has the shorter radius, R; but it has the *greater sweep*, Δ, and the *greater* values of T, M, E, M_h and Y. (Compare ¶ 40.) These values may be found by means of the equations in p 891, ¶ 34.

44. Fig 15. **Sub-chains,** c_s, c_i, c_f.* See ¶ 24. Let the curv begin at A, w ft beyond y, and end at B.

*Where it is necessary to distinguish betw the initial and the final sub-chain, we use the subscripts, i and f, respectively. Otherwise we use the subscript, s.

If a b = a diminished chain = *nearly* 100 ft, and $a\,m\,b$ = a unit arc = 100 ft (see ¶20), we have:—

initial sub-arc, $A\,a = 100 - w$;

initial sub-angle, $d_i = D \dfrac{100 - w}{100}$;

initial sub-chain, $c_i = A\,a = 2\,R \sin(d_i/2) = c \dfrac{\sin(d_i/2)}{\sin(D/2)}$ . . (48)

Having located b, we have:—

final sub-angle, $d_f = b\,O\,B = 2\,b\,A\,B$;

final sub-arc, $b\,B = 100 \dfrac{d_f}{D}$;

final sub-chain, $c_f = b\,B = 2\,R \sin(d_f/2) = c \dfrac{\sin(d_f/2)}{\sin(D/2)}$;

$x = B\,z = 100 -$ (final sub-arc, $b\,B$) . . . . (49)

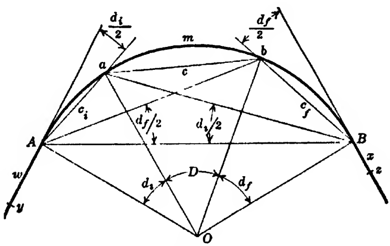

Fig. 15.

45. Fig 15 **With the full chain,** ($c = a\,b = 100$ ft; unit arc, $a = a\,m\,b$, > 100 ft) we have:—

initial sub-chain, $c_i = A\,a = 100\text{ ft} - w$;

for initial sub-angle;

$$\sin \frac{d_i}{2} = \frac{c_i}{2\,R} = c_i \frac{\sin(D/2)}{100} \quad \text{. . . . . (50)}$$

Having located b, we have, as before:—

final sub-angle, $d_f = b\,O\,B = 2\,b\,A\,B$; and

final sub-chain, $c_f = b\,B = 2\,R \sin(d_f/2) = 100 \dfrac{\sin(d_f/2)}{\sin(D/2)}$;

but $x = B\,z = 100\text{ ft} -$ final sub-*chain*, c_f . . . . (51)

46. Fig 15. **Approximate or "nominal" values of c_s* and of d. With either full or diminisht unit chain,** let

c_s = the *true* value of either sub-chain, as found above;
d = the *true* value of the corresponding sub-angle;
c = the full or diminisht chain used, as the case may be;
c_n = $c\,d/D$ = the approx or "nominal" value of c_s;
d_n = $D\,c_s/c$ = the approx or "nominal" value of d.

---

*Where it is necessary to distinguish betw the initial and the final sub-chain, we use the subscripts, i and f, respectively. Otherwise we use the subscript, s.

Then

$$c_s > c_n; \quad d_n > d; \quad \frac{c_s}{c_n} = \frac{d_n}{d} \quad \ldots\ldots\ldots (52)$$

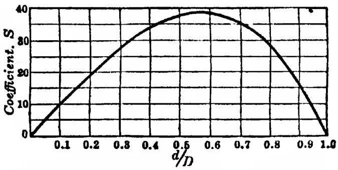
and, for 100 ft chain or 100 ft unit arc, approx,

$$c_s - c_n = S(Q - 1) \quad \ldots\ldots\ldots\ldots\ldots\ldots (53)$$

where Q = value of $\frac{\text{arc}}{\text{chord}}$ (table, ¶ 37) for the given value of D,

and S = a coefficient as per Fig 16, below.

Fig. 16.



Coefficient, S, for deducing true value, c_s, of sub-chain, from its "nominal" value, $c_n = cd/D$.

47. For any value, c, of the chain or unit arc other than 100 ft, we have:—

$$c_s - c_n = S\ (Q - 1)\ c/100 \ldots\ldots\ldots\ldots\ldots\ldots (54)$$

48. From ¶ 27, we have, approx:—

$\sin 0°\ 1'$: $\sin(d/2)$ = 1 min : $d/2$ in mins; or

$$d/2 \text{ in mins} = \sin(d/2) \div 0.0002909 = 3437\ \frac{\text{sub-chain}}{2\ R} \ldots (55)$$

49. If, in a given circular curv, the full chain and the sub-chain be divided into the same number of equal parts, their ordinates are approx as the squares of the chain lengths.

COMPOUND CURVS

Compare Reverse Curvs, ¶ ¶ 70, etc.

Definitions

50. Figs 17, 18. Compound curvs. When two consecutiv curvs, AP and PB, of unequal radii, R_g and R_s, curv in the same direction (both to the right or both to the left), they are said to be compounded, and the entire curv, APB, is called a compound curv.

51. Branches. The two portions, AP and PB, of the compound curv, are called its branches. They lie on the same side of the common tangent, $v_g\,v_s$. Their meeting point, P, or common tangent point, is the point, "C. C." of change from *curv* to *curv*. It is also called the "P. C. C." or point of compound curvature. See ¶ 2.

52. Radii. The centers, O_g and O_s, of the two branches, are necessarily in a straight line with the P. C. C. (P): *i. e.*, the two radii, being normal to the common tangent, $v_g\,v_s$, at P, coincide in $O_s\,P$. At A and at B, the radii are normal respectively to the semitangents, $A\,V$, $V\,B$, of the entire curv.

53. The vertex, V, of the entire compound curv, is usually *not* (as it is in Fig 17) in $O_g\,P$ produced. See ¶ ¶ 57 and 146.

54. Subscripts. R_g is the *greater* radius; and its sweep, semitangent, etc., are lettered Δ_g (or simply g), T_g, etc., respectivly; and similarly for the *shorter* radius, R_s, with its sweep, Δ_s, (or s), semitangent, T_s, etc.

55. The semitangents of the entire compound curv, $A\ P\ B$, are T_g and T_s, perpendicular respectivly, at A and at B, or vice versa, to the radii, R_g and R_s. The semitangents of the two branches, respectivly, are $t_g = v_g P$, and $t_s = P v_s$.

56. If (as usual, and as in Figs 17, 18) $\Delta < 180°$, we find $T_g > T_s$; but, when $\Delta > 180° < 360°$, $T_g < T_s$. See ¶ 69. If $\Delta = 180°$, T_g and T_s are infinit. and there is no vertex, V.

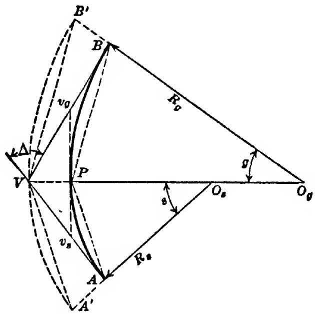


Fig. 17.

Equations

57. Fig 17. In the **special case** where the vertex, V, lies in the common radial line, $O_g\ P$, produced, we have

$$V\ P = R_g \text{ exsec } g = R_s \text{ exsec } s.$$

Hence

$$\frac{R_g}{R_s} = \frac{\text{exsec } s}{\text{exsec } g} = \frac{1 - \cos s}{\cos s} \cdot \frac{\cos g}{1 - \cos g} \ldots\ldots (56)$$

Hence, in this special case, we have $s > g$, or the *shorter* radius, R_s, has the *greater* sweep, s, and vice versa.

In this case, also, we have :—

$T_g = R_g \tan g$; $T_s = R_s \tan s$;

$$\begin{aligned} T_g \tan(g/2) &= T_g \tan V\ B\ P = T_g \tan B'V\ B \\ &= B'B = V\ P = A'A \\ &= T_s \tan(s/2)\text{ ; or} \end{aligned}$$

$$\frac{T_g}{T_s} = \frac{\tan(s/2)}{\tan(g/2)} \ldots\ldots\ldots\ldots\ldots\ldots (57)$$

Sweeps, Δ_g, Δ_s, Δ.

58. Figs 18. The sweeps, Δ_g (or g) and Δ_s (or s) of the two branches, may be equal or unequal; and, in general, either may be the greater; but see the special case of ¶ 57.

Since both branches curv in the same direction (right or left), we have, for the sweep, Δ, of the entire compound curv, $A\ P\ B$:—

$$\Delta = g + s; \quad g = \Delta - s; \quad s = \Delta - g \ldots (58)$$

See also eq (60).

In Fig 18a	In Fig 18b
Draw $Puw \perp O_s B$. Then sin s	Draw $Puw \perp O_g A$. Then sin g

$$= \frac{P\,w}{R_g} = \frac{P\,u}{R_s} = \frac{u\,w}{O_g\,O_s} = \frac{P\,w - P\,u}{R_g - R_s} \quad \ldots . (59)$$

59. Angles, A and B. Let $VAB = A$; $VBA = B$. Then: $\Delta\ (= 180° - AVB) = A + B$; $A = \Delta - B$; $B = \Delta - A$ . . . (60)

See also eq (58).

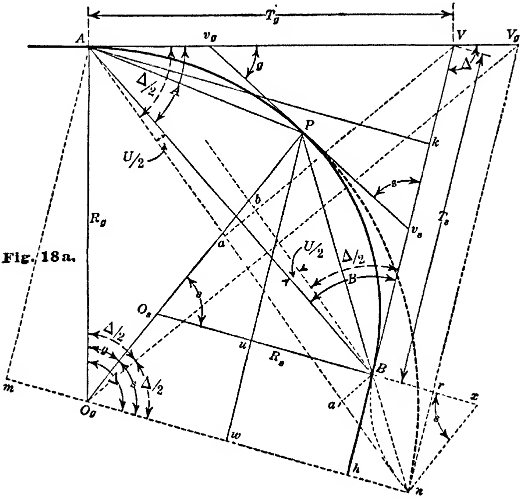

Fig. 18a.

60. Angles V A P and V B P.

$$VAP = g/2; \qquad VBP = s/2;$$
$$VBP + VAP = s/2 + g/2 = (s + g)/2 = \Delta/2$$
$$VBP - VAP = s/2 - g/2 = (s - g)/2 = \Delta/2 - g \quad . . (61)$$

61. Long chord, C_{delta} = **A B.** See also ¶ 64.

In Fig 18a	In Fig 18b
Draw $A\,k \perp B\,V$. Then $A\,k = C_{delta} \sin B = T_g \sin \Delta$	Draw $B\,k \perp A\,V$. Then $B\,k = C_{delta} \sin A = T_s \sin \Delta$

and $C_{delta} = T_g \sin \Delta / \sin B = T_s \sin \Delta / \sin A$ . . . . (62)

See also eqs (66) and (67)

Fig. 18a.	Fig 18b.
62. Produce branch $A P$ to n, making $O_g n \parallel O_s B$. Then P, B and n	Produce branch $B P$ to n, making $O_s n \parallel O_g A$. Then P, n and A

are in a straight line.

Angle, U/2.

Join $A\,n$, and draw $n\,V_g \parallel B\,V$.	Join $B\,n$, and draw $n\,V_s \parallel A\,V$.
Draw $B\,b \parallel A\,n$.	Draw $A\,a \parallel B\,n$.
Let $B\,A\,n\ (= A\,B\,b) = U/2$.	Let $A\,B\,n\ (= B\,A\,a) = U/2$.

Then $A = \Delta/2 - U/2 = (\Delta - U)/2$

$B = \Delta/2 + U/2 = (\Delta + U)/2$ ......(63)

Adding, we have $A + B = \Delta$, as in eq (60);

Subtracting, we have

$B - A = U;\quad B = A + U;\quad A = B - U;$

$U = \Delta - 2A = 2B - \Delta$ ....(64)

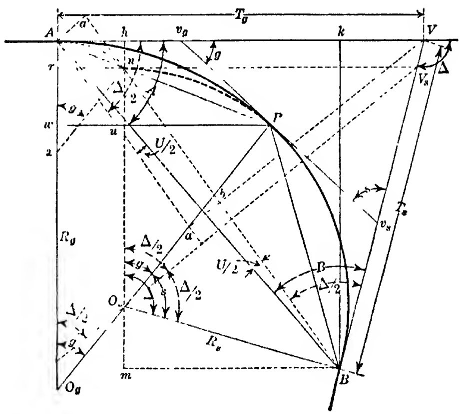

Fig. 18b.

63. Then

In Fig 18a	In Fig 18b
$O_g V_g \perp A\,n$, bisects $A\,n$; $A\,O_g\,n = \Delta$; and $A\,O_g\,V_g = V_g\,O_g\,n = \Delta/2$.	$O_s V_s \perp B\,n$, bisects $B\,n$; $B\,O_s\,n = \Delta$; and $B\,O_s\,V_s = V_s\,O_s\,n = \Delta/2$ ..(65)

64. Long chord, C_{delta} = A B. See also ¶ 61.

Fig. 18a.	*Fig. 18b.*
Draw $V\,a$ and $B\,a' \parallel O_g V_g \perp A\,n$. Then $C_{delta} \sin(U/2) = B\,a'$	Draw $V\,a$ and $A\,a' \parallel O_s V_s \perp B\,n$. Then $C_{delta} \sin(U/2) = A\,a'$

$$= V\,a - V\,b$$
$$= T_g \sin(\Delta/2) - T_s \sin(\Delta/2)$$
$$= (T_g - T_s) \sin(\Delta/2).$$

Hence

$$C_{delta} = (T_g - T_s)\,\frac{\sin(\Delta/2)}{\sin(U/2)} \;\ldots\ldots\ldots\ldots (66)$$

See also eqs (62) and (67).

We have, also

$C_{delta} = \sqrt{A\,k^2 + B\,k^2} =$ $\sqrt{(T_g \sin\Delta)^2 + (T_s - T_g \cos\Delta\dagger)^2}$	$C_{delta} = \sqrt{B\,k^2 + A\,k^2} =$ $\sqrt{(T_s \sin\Delta)^2 + (T_g - T_s \cos\Delta\dagger)^2}$ ....(67)

See also eqs (62) and (66).

65. Semitangents, T_g and T_s. Draw $n\,x \parallel = O_g O_s = R_g - R_s$,

meeting $O_s B$ produced, in x Then $B\,x\,n = s$. Draw $n\,r$ and $A\,m \parallel B\,V \perp O_s\,x$. Then $Ak = T_g \sin\Delta$ $= mn - hn$ $= mn - Br$ $= R_g \text{ vers}\Delta - (R_g - R_s) \text{ vers } s$	meeting $O_g A$ in x. Then $A x n = g$. Draw $n\,r$ and $B\,m \parallel A\,V \perp O_g\,x$. Then $B\,k = T_s \sin\Delta$ $= mn + hn$ $= mn + Ar$ $= R_s \text{ vers}\Delta + (R_g - R_s) \text{ vers } g$ ....(68)

66. Branch semitangents, t_g and t_s; and **common tangent,** $v_g\,v_s$.

$$\begin{matrix} t_g & (= v_g P) & = & R_g \tan(g/2) \\ t_s & (= v_s P) & = & R_s \tan(s/2) \end{matrix}$$

Common tangent, $v_g\,v_s$, $= t_g + t_s$ ....(69)

$B\,n = 2(R_g - R_s) \sin(s/2)$.	$A\,n = 2(R_g - R_s) \sin(g/2)$ ....(70)

67. Figs 18*a*, 18*b*. Eqs (58) and (68) enable us to find required elements of compound curvs, other elements being given. See examples, below.

Examples.

Given	**Required** elements indicated by **bold** type
$R_g\ R_s\ g\ s$	Δ is given immediately by Eq (58) and **T_g** and **T_s** by Eq (68)
$R_s\ T_s\ \Delta\ s$	**g** $= \Delta - s$, eq (58) **R_g** $\text{vers } g = T_s \sin\Delta + R_s \text{ vers } g - R_s \text{ vers }\Delta$..(71) **$T_g$** $\sin\Delta = R_g \text{ vers }\Delta - (R_g - R_s) \text{ vers } s$ ......(72)

† See ¶ 69.

R_g T_g Δ g	$s = \Delta - g$, eq (58) $R_s \text{ vers } s = R_g \text{ vers } s + T_g \sin\Delta - R_g \text{ vers } \Delta$ . . . (73) $T_s \sin \Delta = R_s \text{ vers } \Delta + (R_g - R_s) \text{ vers } g$ . . . . . . (74)
R_g R_s T_g Δ	$(R_g - R_s) \text{ vers } s = R_g \text{ vers } \Delta - T_g \sin \Delta$ . . (75) $g = \Delta - s$, eq (58) $T_s = R_g \sin \Delta - (R_g - R_s) \sin s - T_g \cos \Delta^*$ . . . (76)
R_s T_g T_s Δ	$\text{Tan } (g/2) \times (T_g + T_s \cos \Delta^* - R_s \sin \Delta)$ $= T_s \sin \Delta - R_s \text{ vers } \Delta$ . . . . (77) $s = \Delta - g$, eq (58) $R_g \sin g = R_s \sin g + T_g + T_s \cos \Delta^* - R_s \sin \Delta$. (78)
R_g T_g T_s Δ	$\text{Tan } (s/2) \times (R_g \sin \Delta - T_g \cos \Delta^* - T_s)$ $= R_g \text{ vers } \Delta - T_g \sin \Delta$ . . . . (79) $g = \Delta - s$, eq (58) $R_s \sin s = R_g \sin s - R_g \sin \Delta + T_g \cos \Delta^* + T_s$. (80)

68. Figs 18. Given angles, A and B, long chord $C_{delta} = A\ B$, and either R_g or R_s, to find **g, s and the other radius.** Find $\Delta = A + B$; T_g and T_s by eq (62).

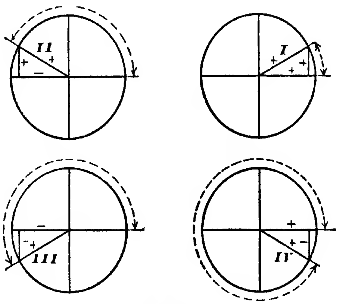

Fig. 19.

Then, having R_g (or R_s), T_g, T_s and Δ, find g, s and R_s (or R_g) by eqs (77) to (80).

69. Angles over 90°. When, owing to the considerable sweep of the curv, or to other causes, any of the angles involvd exceeds 90°, attention must be given to the fact that the algebraic signs (+ and −) vary with the several quadrants of the circle. See "Positiv and negativ signs", p 97*a*.

Thus, Fig 19

In quadrant	I	II	III	IV
Including angles from	0° to 90°	90° to 180°	180° to 270°	270° to 360°
Sine and cosecant are Tangent and cotangent are Secant and cosine are	plus plus plus	plus minus minus	minus plus minus	minus minus plus

*In our Figs 18, $\Delta > 90°$, and cos Δ is therefore ***negativ.*** See ¶ 69.

REVERSE CURVS

Definitions

70. Figs 20-23. Compare Compound Curvs, ¶ ¶ 50-69. When two consecutiv circular curvs, AP and PB, of equal or of unequal radii, R_a and R_b, curv in *opposit* directions (either one to the right, and the other one to the left) they are said to be reverst, and the combination is called a reverse curv. Reverse curvs are sometimes unavoidable, as in some crossovers and turnouts; but elsewhere they should be avoided.

71. The two branches, AP and PB, lie on *opposit* sides of the common tangent, $v_a v_b$. Their meeting point, P, or the common tangent point, is the point, "C C." of change from *curv* to *curv;* or point of reverse curvature, "P. R. C." See ¶ 2.

72. The centers, O_a and O_b, of the two branches, are necessarily in a straight line with the C. C. (P), **the two radii** being normal to the common tangent, $v_a v_b$, at P. At A and at B, the radii are normal respectivly to the tangents, AV, VB, of the entire curv. The vertex, V, is on the side of *the greater sweep.*

73. The semitangents of the entire reverse curv are $T_a = AV$ and $T_b = BV$. See ¶ 77 The semitangents of the two branches, respectivly, are $t_a = v_a P = v_a A$, and $t_b = v_b P = v_b B$. **Common tangent,** $v_a v_b = t_a + t_b$.

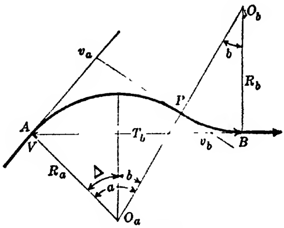

Fig. 20a.

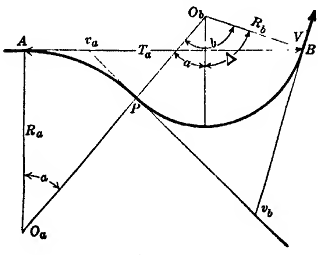

Fig. 20b.

74. Figs 20.
Fig 20*a*. If V coincides with A, we have

$$T_a \ (= AV) = 0, \text{ and } T_b \ (= VB) = AB.$$

Fig 20*b*. If V coincides with B, we have

$$T_b \ (= BV) = 0, \text{ and } T_a \ (= VA) = AB.$$

75. The sweeps, Δ_a and Δ_b (or, simply, a and b) of the two branches, may be equal or unequal, and either may be the greater.

76. Since the two branches deflect in *opposit* directions, the resultant deflection, Δ, due to the reverse curv as a whole, is

$$\Delta = \textit{difference} \text{ between } a \text{ and } b \quad \text{.......... (81)}$$

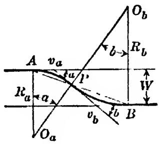

Fig. 21.

77. Fig 21. When the tangents are parallel, we have $a = b$, and Δ ($= a - b$) $= 0$. Then $T_a (= A\,V)$ and $T_b (= B\,V)$ are infinit, there being no vertex, V. See ¶ 79.
Also, P is in the line $A\,B$.

Equations

78. Figs 22 and 23. **Semitangents,** $A\,v_a$ and $v_b\,B$, **non parallel.** The P. R. C (P) is not in $A\,B$.

Radii unequal. Figs 22.	**Radii equal.** Figs 23. $R_a = R_b = R$

From the semi tan, $A\,v_a$, at A, lay off $X\,A\,D = Z\,D\,A = \Delta/2$.

Measure chord $A\,D = 2\,R_a \sin(\Delta/2)$	Measure chord $A\,D = 2\,R \sin(\Delta/2)$.

Then D is a point in the curv $A\,P$ (produced, Figs 22*b*, 23*b*). Draw $O_a\,D \parallel O_b\,B$ Then $A\,O_a\,D = \Delta$. Thru D, draw tangent, $Z\,N \parallel B\,V$, and distant $D\,B' = W$, from $B\,V$ From D lay off arc $D\,P$ ($D\,O_a\,P = b$), locating P

Radii unequal:

Measure the chords, $D\,P$ and $P\,B$. Then

$$D\,B = D\,P + P\,B$$
$$= W/\sin(b/2)$$
$$= 2\,(R_a + R_b)\sin(b/2) \quad \text{.... (82)}$$
$$R_b = R_a\,P\,B/D\,P$$
$$= \frac{D\,B}{2\sin(b/2)} - R_a \quad \text{.. (83)}$$

Common tangent,

$$v_a\,v_b = t_a + t_b$$
$$= R_a \tan\frac{a}{2} + R_b \tan\frac{b}{2} \quad \text{.... (84)}$$

Radii equal:

Measure the chords, $D\,P = P\,B$. Then

$$D\,B = D\,P + P\,B$$
$$= 2\,D\,P = 2\,P\,B$$
$$= W/\sin(b/2)$$
$$= 4\,R\sin(b/2) = 2\sqrt{W\,R} \quad \text{.... (82')}$$
$$R = R_a = R_b$$
$$= \frac{D\,P}{2\sin(b/2)} = \frac{P\,B}{2\sin(b/2)} \quad \text{.... (83')}$$

Common tangent,

$$v_a\,v_b = t_a + t_b$$
$$= R\left(\tan\frac{a}{2} + \tan\frac{b}{2}\right) \quad \text{.... (84')}$$

$$\sin D\,B\,v_b = \sin(b/2) = W/D\,B \quad \text{............ (85)}$$

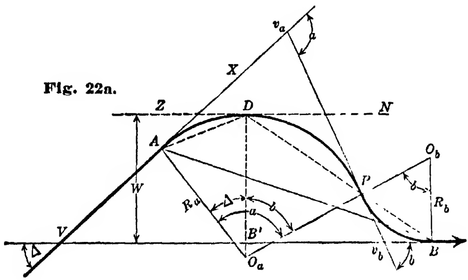
$A\,B = A\,P + P\,B$	$A\,B = 2\,A\,P = 2\,P\,B$
$= 2\,(R_a + R_b) \sin(a/2)$	$= 4\,R \sin(a/2)$
$= \sqrt{2\,W\,(R_a + R_b)}$ ..(89)	$= \sqrt{4\,W\,R} = 2\,\sqrt{W\,R}$ ....(89′)
	$R = A\,B^2/4\,W$ ....(90)

Fig. 22a.



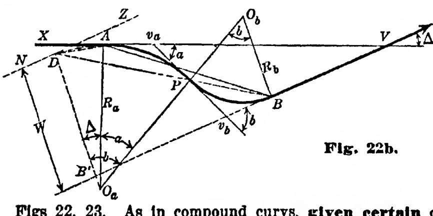


Fig. 22b.

80. Figs 22, 23. As in compound curvs, **given certain** of the seven elements, R_a, R_b, T_a, T_b, a, b, Δ; **the others** may be found. For instance:—

Given	Required quantities indicated by **bold type**
	In all cases, $\Delta = a - b$ or $b - a$.
$R_a\ R_b\ T_a\ \Delta$	$\mathbf{vers\ b} = \dfrac{R_a \text{ vers } \Delta + T_a \sin \Delta}{(R_a + R_b)}$ .... (91)
	$\mathbf{T_b} = T_a \cos \Delta + R_a \sin \Delta \pm (R_a + R_b) \sin b$ ... (92)
$R_a\ R_b\ T_b\ \Delta$	$\mathbf{vers\ a} = \dfrac{R_b \text{ vers } \Delta + T_b \sin \Delta}{(R_a + R_b)}$ .... (93)
	$\mathbf{T_a} = T_b \cos \Delta + R_b \sin \Delta \pm (R_a + R_b) \sin a$ ... (94)

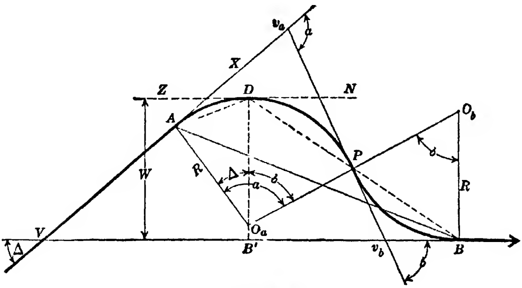

Fig. 23a.

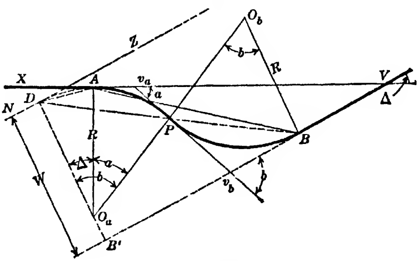

Fig. 23b.

CURV LOCATION.

81. Fig 24. By Peripheral or Deflection Angles. See ¶¶ 4, &c. Example. Instrument at the T.C. (*A*), or at the C.T. (*B*). (For other points, see ¶¶ 84 &c.)

(1) If the chaining begins at A.

To locate	Inst at A — Inst at B — Lay off angle	Chains†
A	—— $VBA^* = \Delta/2 = d_i/2 + 3\,D/2 + d_f/2$	*
a	$VAa = ABa = AOa/2 = d_i/2$	$c_i = Aa$
b	$VAb = ABb = AOb/2 = d_i/2 + 1\,D/2$	$c = ab$
c	$VAc = ABc = AOc/2 = d_i/2 + 2\,D/2$	$c = bc$
d	$VAd = ABd = AOd/2 = d_i/2 + 3\,D/2$	$c = cd$
B	VAB —— $= \Delta/2 = d_i/2 + 3\,D/2 + d_f/2$	$c_f = dB$

(2) If the chaining begins at B.

To locate	Inst at A — Inst at B — Lay off angle	Chains
B	VAB^* —— $= \Delta/2 = d_f/2 + 3D/2 + d_i/2$	*
d	$BAd = VBd = BOd/2 = d_f/2$	$c_f = Bd$
c	$BAc = VBc = BOc/2 = d_f/2 + 1D/2$	$c = dc$
b	$BAb = VBb = BOb/2 = d_f/2 + 2D/2$	$c = cb$
a	$BAa = VBa = BOa/2 = d_f/2 + 3D/2$	$c = ba$
A	—— $VBA = \Delta/2 = d_f/2 + 3D/2 + d_i/2$	$c_i = aA$

82. For the tangent, at any given station, as B, we have:—
Sighting back to the T.C., A;
$zBx = VBA = VAB =$ sum of angles laid off, at A, from tan, AV, to given sta, B;

Sighting back to another station, as b;
$zBy = VBb = cbB =$ sum of angles laid off, at b, from tan, bc, to given sta, B.
etc, etc.

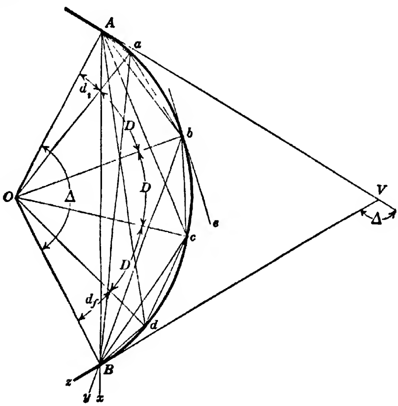

Fig. 24.

---

*Sighting from either end of the curv, to the other end, where the chaining begins, the desired point is located by the intersection of the line of sight with the tan, BV or AV.

†The chains given, c_i, c, etc, refer to their several *chain* angles, VAa, aAb, bAc, etc. The *total* angle, VAc, for instance, requires chains $c_i + c + c$.

Moving the Instrument. Transit Points.*

83. Fig 24. When the sum, *V A d*, of the angles, laid off from the tangent with the inst at one point, as *A*, exceeds say 15° or 20°, then, with the rear end of the chain held at the last preceding sta, as *c*, the free end of the chain may deviate materially from its correct position, at *d*, without detection by the transitman; and this difficulty is increast by the increast length of sight.

84. In this case, or when an obstacle prevents the laying-off of the next angle, the instrument is moved to another point ("transit point"*), on the curv, and the work is continued thence.

85. Liability to error is much reduced by pursuing, thruout, a systematic method of procedure, as below.

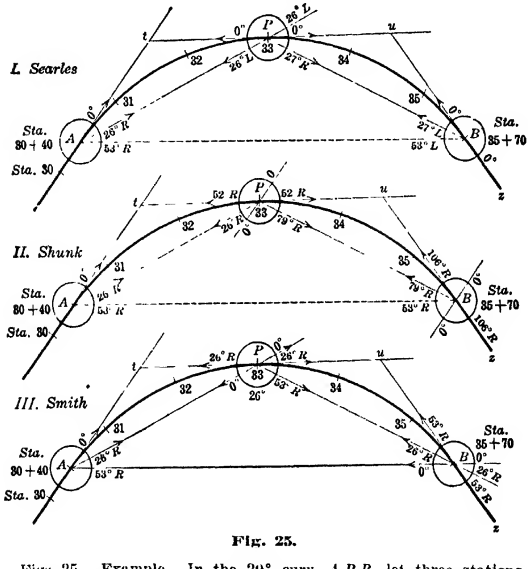

Fig. 25.

Figs 25. Example. In the 20° curv, *A P B*, let three stations, Nos. 31, 32 and 33 (*P*), be set from the T.C. (*A*, sta 30 + 40); then three stations, Nos. 34, 35 and 35 + 70 (*B*), from *P*; and then let the final tangent, *Bz*, be located from the C.T. (*B*, sta 35 + 70).

The circles, at *A*, at *P* and at *B*, in each Fig, show the orientation of the inst, the angles turnd and the resulting vernier readings.

In each of the three Figs (see Figs 25, I) let

angle $t A P = 0.6 \times 10° + 10° + 10° = 26°$;

" $u P B = 10° + 10° + 0.7 \times 10° = 27°$.

*Such points are often called "turning points," but this is liable to confusion with the "turning points" used in *leveling*.

Three methods of procedure are in common use in connection with the removal of the transit to a new inst point. These may be called :—

I. Searles. See "Field Engineering," pp 53, 57, etc.
II. Shunk. See "The Field Engineer," pp 66, etc.*
III. Smith. See Eng News, 1876 Aug 26, p 277, reprinted 1888 Sep 29, p 245 ;* also Cross's "Engineer's Field Book," pp 56 etc.

Method I (Searles) is sufficiently described in the first of the three sections of the comparativ table in ¶ 86.

Method II (Shunk) may be made clearer by the following application of it to the same case See Figs 25, II. Here all the angles are to the right (R) of zero.

Inst at	A	P	B
Sight to old point,	t	A	P
Vernier read'g on old point,	0°	$tAP = tPA = 26°$	$2\,tAP + uPB = 52° + 27° = 79°$
Add	0°	$APt = tAP = 26°$	$PBu = uPB = 27°$
Sight to tan,	At	tu	uz
Vernier reading on tan,	0°	$tAP + APt = 2\,tAP - 0° = 2 \times 26° - 0° = 52°$	$79° + 27° = 2 \times 79° - 2\,tAP = 158° - 52° = 106°$
Add	$tAP = 26°$	$uPB = 27°$	
Sight to new point,	P	B	
Vernier read'g on new point,	$tAP = 0° + 26° = 26°$	$2\,tAP + uPB = 52° + 27° = 79°$	
Move to new point,	P	B	

After removing the instrument from an old point, p (not shown), to a new point, p', the vernier reading, C, which will place the telescope in the new tangent, is determind thus :—Let

A = vernier reading on sighting new point, p', from p;
B = vernier reading on sighting along old tangent, at p;
C = vernier reading on sighting along new tangent, at p'.

Then,

$$C = 2A - B.$$

Method III (Smith) is described in ¶ ¶ 89 to 91.

86. The following table outlines the method of procedure by the three methods respectivly.
U. M. = upper motion of transit, L. M. = lower motion of transit.
R = right; L = left.

*In his 9th edition, 1890, Mr. Shunk described the "Smith" method (III), accrediting it to Mr. Robert Burgess, C.E., who described it in Eng News, 1888 Sep 22.

†For the sake of uniformity, we here assume that, in using method III (Smith), we move the inst either to P or to B, and that, after so moving, we sight to the same stations (A and P, respectivly) as in methods I and II; but, in fact, with method III, the condition, described in ¶ 90, will obtain, no matter to what station we remove, or to what station we sight from it. See ¶ 91.

89. In Method III (Smith), Figs 25, III, before beginning to run the curv, calculate, and enter in the field book (as in last column of table, ¶ 88), opposite each sta (as 30 + 40, 31, etc), and opp any other points, in the curv, which, for any reason, it may be thought desirable to locate, the total angle (as *t A t* = 0°, *t A* 31, *t A P*, *t A B*, etc), betw the *original* tangent, *A t*, and the chord, *A*-31, *A*-*P*, *A*-*B*, etc) from *A* to such sta, *as tho each of the points, thruout the entire curv, were to be located from the point of curv, A.*

90. Then, after setting up at any point whatever in the *curv*, set the vernier to the angle so recorded in the field book opp *any* other convenient point, *x*, in the curv, and sight to *x*, thus orienting the inst. Then, if the vernier be set, by the upper motion, to the reading recorded, as above, opp any *other* point, *y*, in the curv, the inst will be sighted at *y*. With the vernier at the angle recorded opp the *point occupied*, the inst is in the *tan thru that point.*

*For the sake of uniformity, we here assume that, in using method III (Smith), we move the inst either to *P* or to *B*, and that, after so moving, we sight to the same stations (*A* and *P*, respectivly) as in methods I and II; but, in fact, with method III, the condition, described in ¶ 90, will obtain, no matter to what station we remove, or to what station we sight from it. See ¶ **91.**

91. If the sharpness of the curv is exprest in a whole number of degrees, if the curv begins with a sub-chain, and if many stations are to be set, it may be worth while to **make an arbitrary addition to each angle,** so as to give, to the full stations, angles exprest in a whole number of degrees (or in degs and half degs); thus simplifying the calculations.† For instance, in a 3° curv, if the actual angles be as in line A, below, we may add 0° 18′ to each angle, making them read as in line *B*.

Station	30 + 20 (*A*)	31	32	33	34	34 + 40 (*B*)
A	0°	1° 12′	2° 42′	4° 12′	5° 42′	6° 18′
B	0° 18′	1° 30′	3° 0′	4° 30′	6° 0′	6° 36′

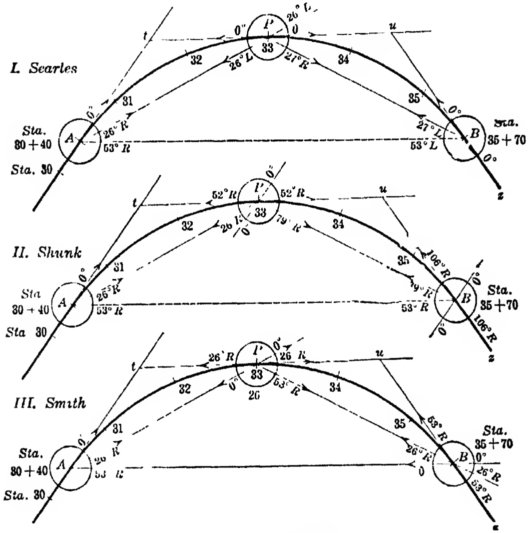

Fig. 25. (Repeated.)

Miscellaneous Methods.

92. Locating a curv without a transit. Fig 26. Let *a b*, *b c*, be chains; *a b* = *b c* = *c*; let *a t* and *b n* be tangents at *a* and at *b*, respectively. Produce chord *a b* to *f*, and make *a t* = *b f* = *a b* = *c*. Then :—

$$t\,b = 2\,c\sin(D/4)\,;\qquad f\,c = 2\,c\sin(D/2) = 2\,c\frac{c}{2\,R} = \frac{c^2}{R}\,. \quad . . (95)$$

†T. Appleton. Assn Engng Socs, Jour, March 1883.

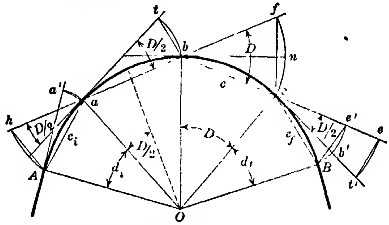
93. **The dists, $t\,b$ and $f\,c$, may be used for locating a curv without a transit.** Thus:—

(1) Having laid off $a\,t$ ($=c$) along the tangent, $a\,t$, to locate b; from a, lay off $a\,b$ ($=c$) to meet $t\,b$ laid off from t.

(2) Having laid off $b\,f$ ($=c$) along the chord $a\,b$ produced, to locate c; from b, lay off $b\,c$ ($=c$) to meet $f\,c$ laid off from f.

(3) Having laid off $c\,e$ ($=c$) along the chord $b\,c$ produced, to find the tangent, $c\,t'$, at c; from c, lay off $c\,t'$ ($=c$) to meet $e\,t'$ ($=t\,b$) laid off from e

Fig. 26.



94. For the sub-chains, $A\,a = c_i$, and $c\,B = c_f$, **sub-angles,** d_i and d_f, etc, we have the following equations.—

Distances	Angles	Approximate
$a'\,a = 2\,c_i \sin(d_i/4)$	$\sin(d_i/2) = \dfrac{c_i}{2\,R}$	$a'\,a = t\,b\,\dfrac{c_i^2}{c^2}$ . . (96)
$B\,b' = 2\,c_f \sin(d_f/4)$	$\sin(d_f/2) = \dfrac{c_f}{2\,R}$	$B\,b' = e\,t'\,\dfrac{c_f^2}{c^2}$ . . (97)
$A\,h = 2\,c_i \sin(A\,a\,h/2)$	$A\,a\,h = \dfrac{D}{2} + \dfrac{d_i}{2}$	$d_i = D\,\dfrac{c_i}{c}$ . . . . (98)
$B\,e' = 2\,c_f \sin(B\,c\,e'/2)$	$B\,c\,e' = \dfrac{D}{2} + \dfrac{d_f}{2}$	$d_f = D\,\dfrac{c_f}{c}$ . . . . (99)

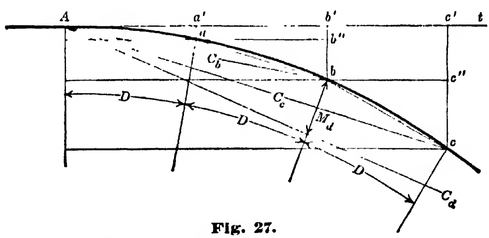


Fig. 27.

95. By Offsets from Tangent, A t. Fig 27. Let R = radius; c = chain length, $A\,a$, $a\,b$, etc; C_b, C_c, C_d, etc = long chord $A\,b$, $A\,c$, $A\,d$, etc, from A to 2d, 3d, 4th, etc station: M_b, M_c, M_d, etc = mid ord for C_b, C_c, C_d, etc; $D/2 = a'A\,a$; $3\,D/2 = b''a\,b$; $5D/2 = c''b\,c$, etc. Then

Distances on tangent

$$A\,a' = c\cos(D/2) = R\sin D \quad\ldots\ldots\ldots\ldots \quad = C_b/2 \ldots\ldots (100)$$

$$A\,b' = c\,[\cos(D/2) + \cos(3\,D/2)] = R\sin(2\,D) \quad\ldots\ldots\ldots\ldots \quad = C_d/2 \ldots\ldots (101)$$

$$A\,c' = c\,[\cos(D/2) + \cos(3\,D/2) + \cos(5\,D/2)] = R\sin(3\,D) \quad\ldots\ldots\ldots\ldots \quad = C_f/2 \ldots\ldots (102)$$

Offsets from tangent

$$a'\,a = c\sin(D/2) = c^2/(2\,R) = R \text{ vers } D = M_b \quad\ldots\ldots\ldots (100a)$$

$$b'\,b = c\,[\sin(D/2) + \sin(3\,D/2)] = C_b \sin b'\,A\,b = C_b \sin D = (C_b)^2/(2\,R) = R \text{ vers } 2\,D = M_d \quad\ldots\ldots\ldots (101a)$$

$$c'\,c = c\,[\sin(D/2) + \sin(3\,D/2) + \sin(5\,D/2)] = C_c \sin(3\,D/2) = (C_c)^2/(2\,R) = R \text{ vers } 3\,D = M_f \quad\ldots\ldots\ldots (102a)$$

Thus, let $c = 100$ ft; $D = 12°$. Then

For dist $A\,c'$, on tan	For offset, $c'\,c$ from tan
$\cos(D/2) = \cos 6° = 0.99452$	$\sin(D/2) = \sin 6° = 0.10453$
$\cos(3D/2) = \cos 18° = 0.95106$	$\sin(3D/2) = \sin 18° = 0.30902$
$\cos(5D/2) = \cos 30° = 0.86603$	$\sin(5D/2) = \sin 30° = 0.50000$
Sum of cosines = 2.81161	Sum of sines = 0.91355
$Ac' = 2.81161c = 281.16$ ft	$c'\,c = 0.91355c = 91.355$ ft

96. First, from A, line in the points, a', b', c', etc., in the tangent, $A\,t$. Then, from a', b', c', etc., lay off $a'\,a$, $b'\,b$, $c'\,c$, etc., normal to $A\,t$; or lay off $a'\,a$, $b'b$, etc, at random, to intersect $A\,a$, $a\,b$, $b\,c$, etc., each $= c$

97. If, as usual, the curv begins or ends with a sub-chain, it may be preferable to divide the curv (sweep $= \Delta$) into a convenient number, n, of equal parts, each $= \Delta/n$, and substitute Δ/n for D, and $2\,R\sin(\Delta/2n)$ for c, etc

As the work proceeds, and the angles $a\,b\,b''$, $b\,c\,c''$, etc., become more acute, the work becomes less accurate.

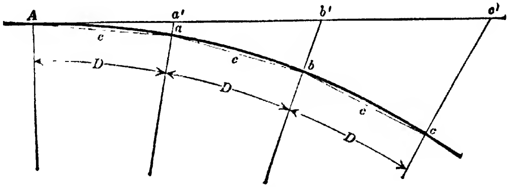

Fig. 28.

98. In Fig 28, the dists, $a\,a'$, $b\,b'$, etc., are **in line with the radii** at a, at b, etc. Here:—

$$A\,a' = R\tan D; \quad A\,b' = R\tan 2\,D; \quad A\,c' = R\tan 3\,D, \text{ etc.} \quad (103)$$

$$a\,a' = R \text{ exsec } D; \; b\,b' = R \text{ exsec } 2\,D; \; c\,c' = R \text{ exsec } 3\,D, \text{ etc.} \quad (104)$$

From A, line in a', b', c', etc. From A and from a', simultaneously, lay off c and $a'\,a$, respectivly, locating a. Then, from a and from b' respectively, lay off, simultaneously, c and $b'\,b$, locating b; and so on. See ¶ 97.

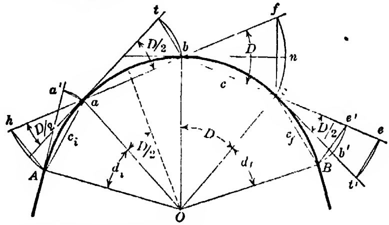
93. The dists, $t\,b$ and $f\,c$, may be used for locating a curv without a transit. Thus:—

(1) Having laid off $a\,t$ ($=c$) along the tangent, $a\,t$, to locate b; from a, lay off $a\,b$ ($=c$) to meet $t\,b$ laid off from t.

(2) Having laid off $b\,f$ ($=c$) along the chord $a\,b$ produced, to locate c; from b, lay off $b\,c$ ($=c$) to meet $f\,c$ laid off from f.

(3) Having laid off $c\,e$ ($=c$) along the chord $b\,c$ produced, to find the tangent, $c\,t'$, at c; from c, lay off $c\,t'$ ($=c$) to meet $e\,t'$ ($=t\,b$) laid off from e

Fig. 26.



94. For the sub-chains, $A\,a = c_i$, and $c\,B = c_f$, **sub-angles,** d_i and d_f, etc, we have the following equations.—

Distances	Angles	Approximate
$a'\,a = 2\,c_i \sin(d_i/4)$	$\sin(d_i/2) = \dfrac{c_i}{2\,R}$	$a'\,a = t\,b\,\dfrac{c_i^2}{c^2}$ . . (96)
$B\,b' = 2\,c_f \sin(d_f/4)$	$\sin(d_f/2) = \dfrac{c_f}{2\,R}$	$B\,b' = e\,t'\,\dfrac{c_f^2}{c^2}$ . . (97)
$A\,h = 2\,c_i \sin(A\,a\,h/2)$	$A\,a\,h = \dfrac{D}{2} + \dfrac{d_i}{2}$	$d_i = D\,\dfrac{c_i}{c}$ . . . . (98)
$B\,e' = 2\,c_f \sin(B\,c\,e'/2)$	$B\,c\,e' = \dfrac{D}{2} + \dfrac{d_f}{2}$	$d_f = D\,\dfrac{c_f}{c}$ . . . . (99)

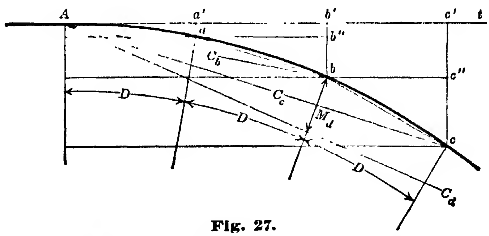


Fig. 27.

95. By Offsets from Tangent, A t. Fig 27. Let R = radius; c = chain length, $A\,a$, $a\,b$, etc; C_b, C_c, C_d, etc = long chord $A\,b$, $A\,c$, $A\,d$, etc, from A to 2d, 3d, 4th, etc station; M_b, M_c, M_d, etc = mid ord for C_b, C_c, C_d, etc; $D/2 = a'A\,a$; $3\,D/2 = b''a\,b$; $5D/2 = c''b\,c$, etc. Then

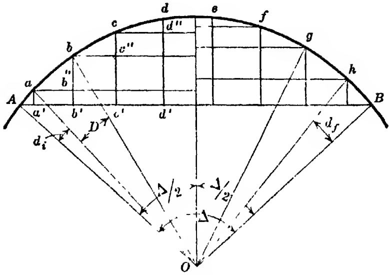

Fig. 31.

Similarly, for the ordinates, $a'\,a$, $b'\,b$, $c'\,c$, etc., we have:

$$a'\,a = c_i \sin\frac{\Delta - d_i}{2};$$

$$b''\,b = c \sin\frac{\Delta - 2\,d_i - D}{2};$$

$$c''\,c = c \sin\frac{\Delta - 2\,d_i - 3\,D}{2}; \text{ etc., and}$$

$$b'\,b = a'\,a + b''\,b; \quad c'\,c = b'\,b + c''\,c, \text{ etc.} \qquad (109)$$

102. Fig 32 *To eliminate sub-chains* (see ¶ 97), let the curv, $A\,P\,B$, be divided into a convenient number of *equal* arcs; and let

c_e = the chord, $A\,a = a\,b$, etc, subtending one of these arcs;
D_e = the central angle, $A\,O\,a$, subtended by c_e;
C, C', C'', etc = the long chords, $A\,B$, $a\,h$, $b\,g$, etc, respectivly;
M, M', M'', etc = the mid ords, $E\,P$, $E'\,P$, $E''\,P$, etc, of C, C', C'', etc, respectivly.

Then,

Abscissas

$$C/2 = A\,E = R\sin(\Delta/2);$$
$$C'/2 = a\,E' = R\sin(\Delta/2 - D_e);$$
$$C''/2 = b\,E'' = R\sin(\Delta/2 - 2\,D_e); \text{ etc.}$$

$$A\,a' = C/2 - C'/2 = c_e \cos a\,A\,a' = c_e \cos\frac{\Delta - D_e}{2};$$

$$a'\,b' = a\,b'' = C'/2 - C''/2 = c_e \cos b\,a\,b'' = c_e \cos\frac{\Delta - 3\,D_e}{2};$$

$$b'\,c' = b\,c'' = C''/2 - C'''/2 = c_e \cos c\,b\,c'' = c_e \cos\frac{\Delta - 5\,D_e}{2};$$

etc; and

$$A\,b' = A\,a' + a'\,b';$$
$$A\,c' = A\,b' + b'\,c'; \text{ etc} \qquad (110)$$

Ordinates

$$M = E\,P = R \operatorname{vers}(\Delta/2)\,;$$
$$M' = E'\,P = R \operatorname{vers}(\Delta/2 - D_c)\,;$$
$$M'' = E''\,P = R \operatorname{vers}(\Delta/2 - 2\,D_c)\,;\ \text{etc.}$$

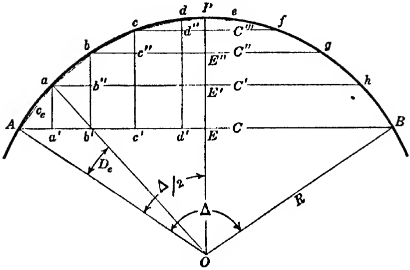

Fig. 32.

$$a'\,a = M - M' = c_c \sin\frac{\Delta - D_c}{2}\,;$$
$$b''\,b = M' - M'' = c_c \sin\frac{\Delta - 3\,D_c}{2}\,;$$
$$c''\,c = M'' - M''' = c_c \sin\frac{\Delta - 5\,D_c}{2}\,;\ \text{etc; and}$$
$$b'b = a'\,a + b''\,b = M - M''\,;$$
$$c'\,c = b'\,b + c''\,c = M - M'''\,;\ \text{etc.} \qquad (111)$$

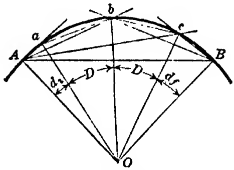

Fig. 33.

103. By Means of Two Transits, without Linear Measurement. Fig 33. Useful where chaining is difficult or impracticable, as in swamps, etc.

Given, any two stations, A and B, each visible from the other;

From each of the two stations, A and B, sight to the other, and lay off the angles found, as below, locating the points, a, b, etc., by means of the intersections of the lines of sight.

Thus, let $a\,b$, $b\,c$, be chains; $A\,a$, $c\,B$, sub-chains. Then, to locate the point b, at the intersection of $A\,b$ and $B\,b$; we have:—

$$b\,A\,B = b\,O\,B/2 = (D + d_f)/2\,;$$
$$b\,B\,A = b\,O\,A/2 = (D + d_i)/2. \qquad (112)$$

Similarly, for point c (intersection of $A\,c$ and $B\,c$,) we have:—

$$c\,A\,B = c\,O\,B/2 = d_f/2\,;$$
$$c\,B\,A = c\,O\,A/2 = (2\,D + d_i)/2 \qquad (112')$$

104. By Long Chords from the Instrument. Fig 34.

Let $a\,b = b\,c = c = 1$ chain; $A\,a = c_i =$ initial sub-chain; $c\,B = c_f =$ final sub-chain.

Then, in Fig 34;

$$t\,A\,a = d_i/2; \qquad A\,a = 2\,R \sin t\,A\,a;$$
$$t\,A\,b = (d_i + D)/2; \qquad A\,b = 2\,R \sin t\,A\,b;$$
$$t\,A\,c = (d_i + 2\,D)/2; \qquad A\,c = 2\,R \sin t\,A\,c;$$
$$t\,A\,B = (d_i + 2\,D + d_f)/2 = \Delta/2; \quad A\,B = 2\,R \sin t\,A\,B. \quad (113)$$

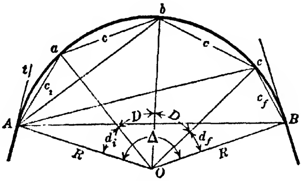

Fig. 34.

105. Platting Auxiliaries. The location of curvs upon the map is greatly facilitated by the use of *templets*, to the proper scale.

106. Wm. F. Shunk's transparent *curv protractor* shows a number of curvs to a scale of 1 inch = 400 ft

107. In Eng News 1902 Jun 19, pp 500-501, Chas H. Quimby Jr. suggests a "*curve projector and scale*" (patent applied for), which is a transparent curv protractor in which each curv is punctured at each 100 ft of its length, by scale, in order that, with a pointed instrument, corresponding points may be markt upon the map beneath.

108. Ordinates. On sharp curvs, additional points, intermediate of stations, may be located by means of ordinates to a chord joining two consecutiv stas. Usually a twine is stretched between the two consecutiv stas, and the ordinates are measured, as nearly as may be at right angles to this, by means of a graduated rod or tape. The points, along the twine, from which ordinates are to be measd (especially the middle point and the two points midway between this and the ends), are distinguisht by knots or otherwise.

109. The permissible dist apart of the ordinates of course depends upon the character of the work and upon the sharpness of the curv. For guiding the earthwork, 50 ft is short enough, or 25 ft for radii less than 1000 ft. For tracklaying, the dist may range from 25 ft on easy curvs, to 10 ft or even 5 ft on the sharpest.

See eqs (32) and (34) to (39), and table of ordinates, pp 898-901.

OBSTACLES.

Methods, other than those here suggested, may be devised to suit these and other cases.

110. Line of sight obstructed. The following suggestions refer to cases arising in the usual method of location by peripheral angles, ¶¶ 81, etc.; but the difficulty may sometimes be avoided by abandoning that method and using instead one or other of the location methods mentiond in ¶¶ 92-104. See also under Surveying, p 281, 5th "hint."

Ordinates

$$M = E\,P = R\,\text{vers}(\Delta/2)\,;$$
$$M' = E'\,P = R\,\text{vers}(\Delta/2 - D_c)\,;$$
$$M'' = E''\,P = R\,\text{vers}(\Delta/2 - 2\,D_c)\,;\ \text{etc.}$$

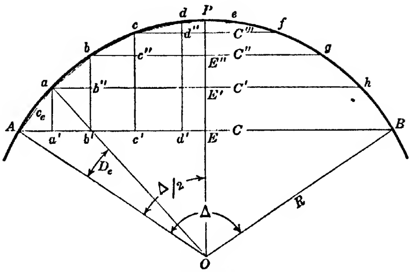

Fig. 32.

$$a'\,a = M - M' = c_c \sin\frac{\Delta - D_c}{2}\,;$$
$$b''\,b = M' - M'' = c_c \sin\frac{\Delta - 3\,D_c}{2}\,;$$
$$c''\,c = M'' - M''' = c_c \sin\frac{\Delta - 5\,D_c}{2}\,;\ \text{etc; and}$$
$$b'b = a'\,a + b''\,b = M - M''\,;$$
$$c'\,c = b'\,b + c''\,c = M - M'''\,;\ \text{etc.} \quad \ldots\ldots\ldots\ldots\ldots (111)$$

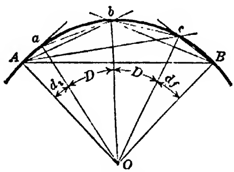

Fig. 33.

103. By Means of Two Transits, without Linear Measurement. Fig 33. Useful where chaining is difficult or impracticable, as in swamps, etc.

Given, any two stations, A and B, each visible from the other; From each of the two stations, A and B, sight to the other, and lay off the angles found, as below, locating the points, a, b, etc., by means of the intersections of the lines of sight.

Thus, let $a\,b$, $b\,c$, be chains; $A\,a$, $c\,B$, sub-chains. Then, to locate the point b, at the intersection of $A\,b$ and $B\,b$; we have:—

$$b\,A\,B = b\,O\,B/2 = (D + d_f)/2\,;$$
$$b\,B\,A = b\,O\,A/2 = (D + d_t)/2. \qquad (112)$$

Similarly, for point c (intersection of $A\,c$ and $B\,c$,) we have:—

$$c\,A\,B = c\,O\,B/2 = d_f/2\,;$$
$$c\,B\,A = c\,O\,A/2 = (2\,D + d_t)/2 \qquad (112')$$

Position of a required point inaccessible.

115. Vertex, V, inaccessible. Fig 37. Given Δ and R or D. Required the curve points, A, B. Measure the dist, $a\,b$, betw any two accessible points on the two tans respectivly. Measure the angles $z\,b\,a$ and $y\,a\,b$, and find $V\,b\,a$ ($= 180° - z\,b\,a$) and $V\,a\,b$ ($= 180° - y\,a\,b$). Then $V\,b\,a + V\,a\,b$ ($= 180° - a\,V\,b$) $= \Delta$; or $a\,V\,b = 180° - \Delta$.

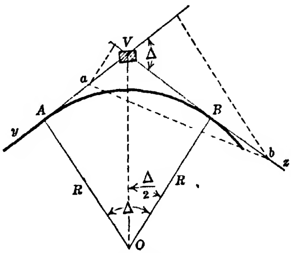

Fig. 37.

Find $V\,a = a\,b \sin V\,b\,a / \sin \Delta$;
and $V\,b = a\,b \sin V\,a\,b / \sin \Delta$. Then :—

$A\,a = A\,V - V\,a = R \tan(\Delta/2) - V\,a$;
$B\,b = B\,V - V\,b = R \tan(\Delta/2) - V\,b$.

Note that, where (as in the last case) $B\,b$ is *negativ*, b is *beyond* B; and $B\,b$ is to be laid off from b *toward* the vertex, V, to locate B.

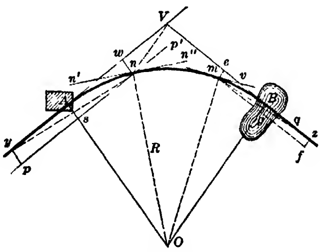

Fig. 38.

Either curv point, A or B, inaccessible.

116. T.C. (A) inaccessible. Fig 38. It is required to locate an accessible point, n, in the curv, and a tan, $n'\,n''$, thru n. The point, n, (preferably a station) must command a sight, $n\,p$, parallel to the tan, $A\,V$.

Let $A\,O\,n$ be the sweep of the arc, $A\,n$, (approx, $A\,O\,n° = D° \times A n/100$). Let $w\,n$ be normal to the tan $A\,V$, and let $n\,s = p\,s$. Then $n\,s = p\,s = w\,A = y\,A = R \sin A\,O\,n$; $w\,n = A\,s = y\,p = R \operatorname{vers} A\,O\,n$; and $V\,w = V\,A - A\,w = T - A\,w = T - n\,s$.

Find the line $n\,p$ (or $n\,p'$), and the point, n, as by one of the two following alternativ methods:—

(1) From p, run $p\,n \parallel A\,V$, making $p\,n = 2\,p\,s = 2\,R \sin A\,O\,n$. Or

(2) From V, lay off $V\,w$ to w; offset $w\,n$ to n; and, from any other point, y, on the tan, $A\,V$, offset $y\,p = w\,n$; or from n, lay off $y\,n\,p$ ($\tan y\,n\,p = wn/wy$); or, from n, lay off $V\,n\,p'$ ($\tan V\,n\,p' = wn/Vw$).

Then, for the tan, at n, lay off $n'\,n\,s = n''\,n\,p' = A\,O\,n$.

117. C.T. (B) inaccessible. Fig 38. It is required to locate a point, as z or q, in the tangent, $V\,B$, beyond B.

We give three alternativ methods, as below:—

From any point, as m, in the curv, at a known dist from B, run $m\,f \parallel$ the tangent, $V\,B$. Then:—

(1) From m, and from any other point, as f, in $m\,f$, lay off offsets $= m\,e = f\,z = R \text{ vers } B\,O\,m$, defining the tangent, $V\,B$, and locating the point, z. Or:—

(2) From m, lay off any angle, $f\,m\,q$, to a line, $m\,q$, intersecting the tan, $V\,B$, and lay off $m\,q = e\,m/\sin f\,m\,q$, to q, which will be in the tan, $V\,B$. Then $B\,q = q\,e - e\,B = me \cot fmq - R \sin BOm$ Or:

(3) From m, lay off $f\,m\,v = B\,O\,m$, locating the tan, $m\,v$, and lay off $m\,v = R \tan(BOm/2)$. Then v will be a point in the tan, $V\,B$. From v sight to m, and lay off $m\,v\,V = B\,O\,m$. Plunge the telescope, sighting along tan, $V\,B$. Then a point, z or q, beyond B, may be found, as required, by the methods given in ¶ 110, etc, for passing obstacles in straight lines.

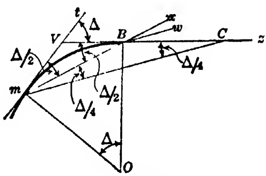

Fig. 39.

118. Fig 39. The **C.T. (B), altho accessible, is not suitable** for a transit point. It is required to find the tangent, $B\,z$.

Set over any convenient point, m, on the curv. Measure the chord, $m\,B$. Let $\Delta =$ the angle, $m\,O\,B$, $=$ sweep of curv betw m and B.

From m, lay off a tan, $m\,t$. Foresight on B. Then angle $t\,m\,B = \Delta/2$. Lay off $B\,m\,C = \Delta/4 = t\,m\,B/2$.

Lay off $B\,C = B\,m$, to meet the line $m\,C$. Then C is a point in the tangent, $B\,z$.

Demonstration.

Since $m\,B\,C$ is isosceles, we have $B\,C\,m = B\,m\,C = \Delta/4$.

Extend $m\,B$, as to x, and draw $B\,w \parallel m\,C$.

Then, from parallelism of sides,
$x\,B\,w\ (= B\,m\,C) = \Delta/4$;
$w\,B\,C\ (= B\,C\,m) = \Delta/4$; and
$x\,B\,C\ (= x\,B\,w + w\,B\,C) = \Delta/2$.

Let $B\,z$ be a tangent to the curv at B.

Then $x\,B\,z$ ($=$ the opp angle $V\,B\,m$) $= \Delta/2 = x\,B\,C$, and $B\,C$ therefore coincides with the tangent, $B\,z$.

CURV PROBLEMS

(See also Re-survey, ¶¶ 155, etc.)

Graphic Solutions

119. Most curv problems may be conveniently solved graphically, with sufficient approximation, and with the added advantage that the drawing shows the relations of the several lines more clearly than they can be shown by mere calculation, and thus reduces the probability of serious error. The scale, to be adopted, will depend upon the nature of the problem and upon the degree of approximation required. It will probably seldom be smaller than 1 inch = 20 feet. The following are given as suggestions. See also ¶ 128.

120. Example. Fig 46. Let it be required to solve graphically the problem in ¶ 131, viz:—Given two curvs, $A\,B'$ and $B\,G$, having diff given radii, R_g and R_s, and diff centers, O_g and O_s, and given the tans, $A\,V$ and $V\,B$, with their sweep, Δ; it is required to find the common radial line, $O_g\,E$, of the two curvs, their respectiv sweeps, g and s, and the shortest dist, d (which will be in the line, $O_g\,E$) betw them; as where it is desired to connect the two curvs by a spiral.

From A, draw $A\,O_g \perp A\,V$ and $= R_g$.
From B, draw $B\,O_s \perp B\,V$ and $= R_s$.
Thru O_g and O_s draw $O_g\,E$, radial to both curvs.
Measure the angles, g and s, and the dist, d.

See letter from C. M. Estabrook, Eng Record 1906 April 7, p 466.

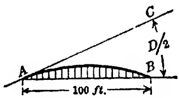

Fig. 40.

121. To draw a circular curv of large radius. Fig 40. Draw a chord, $A\,B$, to represent 100 ft by scale. Divide $A\,B$ into 20 equal spaces. At each division-point, erect an ordinate, normal to the chord, making the lengths of the 19 ordinates to correspond with those given, in table, pp 900-901, for the given sharpness, D. Join the ends of the ordinates.

122. If the curv $A\,B$ is the center line, the curvs for the rails, or for their gage sides, may be drawn at dists from $A\,B$ equal to half the gage. Ordinarily it will be sufficiently accurate if these dists are measured in the directions of the ordinates, already drawn. Otherwise, the dists must be measured radially from the curv, $A\,B$; i. e., at right angles to tangents drawn (see ¶ 124) at the ends of the 19 ordinates.

123. The angle, $C\,A\,B$, betw the 100 ft chord, $A\,B$, and a tangent, $A\,C$, at either end, A or B, of the chord, is $D/2$, where D = the sharpness of the curv = sweep (central angle) subtended by the 100 ft chord.

Fig. 41.

124. To draw a tangent to a curv, at a given point, m, Fig 41. From m, lay off two equal distances, mn, mn, to the curv. Thru m, draw $A\,B$, parallel to $n\,n$. Then will $A\,B$ be tangent to the curv at m.

Field Solutions

125. Many problems are habitually, expeditiously and with sufficient approximation, solved **by trial in the field,** aided, where necessary, by templets or curv protractor (see ¶¶ 105-107) and a field sketching board.

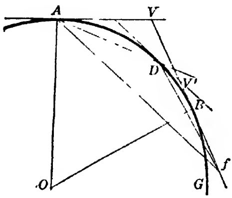

Fig. 42.

126. Example. Fig 42. In a given curv, $A\ G$, to find the point, B, from which a tangent, $B\ f$, may be run thru a given point, f.

This is solved trigonometrically in ¶ 129, Fig 44.

With instrument at any point, as A, in the curv, sight along the tangent, $A\ V$; measure the angle, $V\ A\ f$, and lay off the angle, $V\ A\ D = V\ A\ f/2$. With inst at D, where the line $A\ D$ meets the curv, repeat the process, sighting along the tan, $D\ V'$, and to f, measuring angle $V'\ D\ f$, and laying off $V'\ D\ f/2$ (not shown) to the curv at a point nearer B, and so on, approximating to B. When f is sighted in the tan, $B\ f$, the inst is at the required point, B.

Geometrical Solutions.

Below are given geometrical solutions of a few typical problems of frequent occurrence.

Caution.

127. When Δ is large, look out for necessary **changes in the signs,** + and −. See ¶ 69.

Thus, in Fig 46, ¶ 131, p 940, if $\Delta > 90° < 180°$, we have $\sin\Delta$ positiv, but $\cos\Delta$ negativ; making $B'\ I$ positiv, but $V\ i$ negativ.

In general, the use of the signs, + and −, in our text, refers to our figs, in which, for convenience, the sweep Δ is in general made $< 90°$.

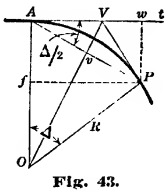

Fig. 43.

128. To pass a curv thru a given point, P. Fig 43.

Given, direction of tangent, $A\ t$; the T.C., A; and the co-ordinates, $A\ w$ and $w\ P$, of the given point, P.

Required, Δ and R (or D), for the curv, $A\ P$. Here

$$\text{Tan}\ (\Delta/2) = w\ P/A\ w;\ R = f\ P/\sin\Delta = A\ w/\sin\Delta = w\ P/\text{vers}\ \Delta.$$

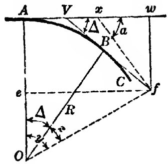
Given R instead of $A\ w$; required, Δ and $A\ w$. Here

$$\text{vers}\Delta = w\ P/R;\quad A\ w\ (= P\ f) = R\sin\Delta.$$

Graphically. Join $A\,P$, measure angle, $w\,A\,P = \Delta/2$, bisect chord $A\,P$ in v, draw a line in the direction $O\,v\,V$, perp to $A\,P$, to intersect $A\,t$ in V, and measure $A\,V$ and $V\,P$. Then V is the vertex of the curv $A\,P$ which joins A and P and is tangential to $A\,t$ at A; $A\,V$ and $V\,P$ are its semitangents; and we have

$$\Delta = 2\ w\,A\,P;\quad R = A\,V/\tan(\Delta/2) = V\,P/\tan(\Delta/2).$$

Fig. 44.



129. Fig 44. In a given curv, $A\,C$, **to find the point, B, whence a tangent, B f, can be run to a given point, f.** For approx instrumental solution, see ¶ 126, Fig 42.

Given, radius, R, curv point, A, direction of initial tan, $A\,V$, and the co-ordinates, $A\,w$ and $w\,f$, of the given point, f.

(If the co-ords, $A\,w$ and $w\,f$, are not given, see below.) Required, the angle, Δ

Thru f, draw $e\,f \perp A\,O$. Then :— $A\,e = w\,f$; $e\,f = A\,w$; and

$$\tan y = \frac{e\,f}{e\,O} = \frac{A\,w}{R - w\,f}, \quad \cos z = \frac{R}{O\,f} = \frac{R}{A\,w/\sin y}; \quad \Delta = y - z.$$

If the co-ords, A w and w f, are not given, and if they cannot easily be measured; take any convenient point, as x, on the initial tan, $A\,V$; measure $x\,f$ and $A\,x$, and the angle, $A\,x\,f$ or its supplement, $a = 180° - A\,x\,f$. Then :—

$A\,w = A\,x + x\,w = A\,x + x\,f\cos a$;
$w\,f = x\,f\sin a = x\,w\tan a$.

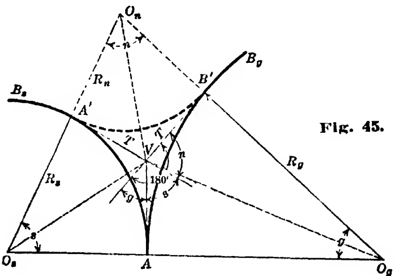


Fig. 45.

130. Fig 45. **Having two curvs,** $A\,B_s$ and $A\,B_g$, starting from a common curv point, A, it is required **to connect them by means of a third** curv, $A'\,B'$, tangent to both curvs and starting from a given point, as A', on one of the two curvs.

Given, both radii, R_s and R_g, and the sweep, Δ_s, (or s) $= A'O_s\,A$, of the curv containing the given point, A';

Required, the common semitangent, T; the sweep, Δ_g (or g) of $A\,B'$, and the sweep Δ_n (or n) and the radius, R_n, for the new curv, $A'\,B'$.

Here we have :—
$T = A\,V = A'\,V = B'\,V = R_s \tan(s/2) = R_g \tan(g/2)$
$= R_n \tan(n/2)$. Hence :—
$\mathrm{Tan}(g/2) = T/R_g$; $n = 180° - (s + g)$; $R_n = T/\tan(n/2)$.

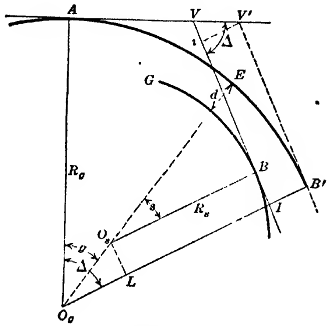

Fig. 46.

131. Fig 46. **Given two curvs,** $A\,E$ and $B\,G$, having diff given radii, R_g and R_s, and diff centers, O_g and O_s, and given the semitans, $A\,V$ and $V\,B$, with their sweep, Δ; it is required to find the common radial line, $O_g\,E$, of the two curvs, their sweeps, Δ_g (or g) and Δ_s (or s) and the shortest dist, d, betw them. (d will be in the line $O_g\,E$, which joins the centers, O_g and O_s, of the two curvs) For graphic solution, see ¶ 120.

Draw $O_g\,B' \perp V\,B$, and extend curv $A\,E$ to intersect $O_g\,B'$ in B'. Draw $V'\,B' \parallel V\,B$. From V' draw $V'\,i \perp V\,B$. Then :—

$B'\,V' = A\,V' = R_g \tan(\Delta/2)$; $V\,V' = A\,V' - A\,V$;
$B'\,I = V'\,i = V'\,V \sin\Delta$; $V\,i = V'\,V \cos\Delta$.

Draw $O_s\,L \perp O_g\,B'$. Then :—
$O_s\,L = B\,I = B'\,V' + V\,i - V\,B$;
$O_g\,L = O_g\,B' - L\,I - B'\,I = R_g - R_s - B'\,I$;

$$\mathrm{Tan}\,s = O_s\,L/O_g\,L;$$
$$\Delta_g = \Delta - \Delta_s; \text{ and}$$
$$d = R_g - R_s - (O_g\,L) \sec s.$$

See letter from Wm. R. Dunham, Jr., Eng Record, 1906, Apr 7, p 466.

Changes of Location.

132. In the following, R, T, E, etc, A, V, B, Δ, etc, indicate the given radius, semitan, ext dist, etc, T. C., vertex, C. T., sweep, etc, for the *existing* curv; and R', T', E', etc, A', V', B', Δ', etc, indicate corresponding lengths, points and angles for the *new* curv. In general, *solid* lines, in the Figs, refer to the *existing* curv; *dotted* lines to the *new* curv, or to demonstration of formulas.

Tangents Unchanged.

133. Fig 47. Change of curv joining two given tans (Δ and V constant); requiring change of given R, T and E ($E = V\,P$).

Here, T ($= A\,V$) $= R \tan(\Delta/2)$; T' ($= A'\,V$) $= R' \tan(\Delta/2)$; $T - T' = AA'$; E ($= V\,P$) $= R\,\mathrm{exsec}(\Delta/2) = T \tan(\Delta/4)$; E' ($= V\,P'$) $= R'\,\mathrm{exsec}(\Delta/2) = T' \tan(\Delta/4)$; $E - E' = P\,P'$; $R - R' = (O\,O') \cos(\Delta/2)$.

Therefore :—

1. Given T'; reqd R' and E'.

$$R - R' = (T - T') \cot(\Delta/2);$$
$$E - E' = (R - R') \operatorname{exsec}(\Delta/2) = (T - T') \tan(\Delta/4)$$

2. Given E'; reqd R' and T'.

$$R' = R\,E'/E; \quad R - R' = \frac{E - E'}{\operatorname{exsec}(\Delta/2)};$$
$$T - T' = (R - R') \tan(\Delta/2) = (E - E') \cot(\Delta/4).$$

3. Given R'; reqd T' and E'.

$$T - T' = (R - R') \tan(\Delta/2);$$
$$E - E' = (R - R') \operatorname{exsec}(\Delta/2) = (T - T') \tan(\Delta/4).$$

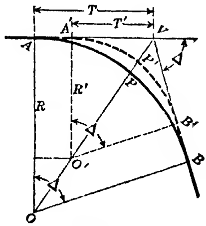

Fig. 47.

134. Changes in Tangents. Where only one of the tans is changed, we assume, for the sake of uniformity, that this is the *final* tan, the *initial* tan remaining unchanged; but, with the proper changes in the lettering, the instructions given apply equally to the reverse case; *i. e.*, where the *initial* tan is changed, the *final* tan remaining unchanged.

One tangent shifted parallel with itself (Δ constant). Tan point, B, changed.

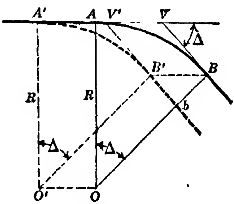

Fig. 48.

135. (1) Fig 48. Radius, R, constant; curv point, **A, shifted.** $A\,A'$, $B\,B'$, $O\,O'$, $V\,V'$ equal and parallel.

Given, dist, $B\,b$, betw tans. Reqd, the shift, $A\,A'$.

$$A\,A' = B\,B' = \frac{B\,b}{\sin \Delta}.$$

Here we have :—

$T = A\,V = A'\,V = B'\,V = R_s \tan(s/2) = R_g \tan(g/2)$
$= R_n \tan(n/2)$. Hence :—

$\text{Tan}(g/2) = T/R_g;\quad n = 180° - (s + g);\quad R_n = T/\tan(n/2)$.

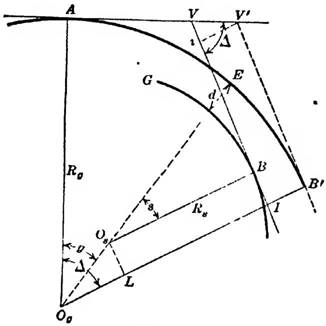

Fig. 46.

131. Fig 46. **Given two curvs,** $A\,E$ and $B\,G$, having diff given radii, R_g and R_s, and diff centers, O_g and O_s, and given the semitans, $A\,V$ and $V\,B$, with their sweep, Δ; it is required to find the common radial line, $O_g\,E$, of the two curvs, their sweeps, Δ_g (or g) and Δ_s (or s) and the shortest dist, d, betw them. (d will be in the line $O_g\,E$, which joins the centers, O_g and O_s, of the two curvs) For graphic solution, see ¶ 120.

Draw $O_g\,B' \perp V\,B$, and extend curv $A\,E$ to intersect $O_g\,B'$ in B'. Draw $V'\,B' \parallel V\,B$. From V' draw $V'\,i \perp V\,B$. Then :—

$B'\,V' = A\,V' = R_g \tan(\Delta/2)$; $V\,V' = A\,V' - A\,V$;
$B'\,I = V'\,i = V'\,V \sin\Delta$; $V\,i = V'\,V \cos\Delta$.

Draw $O_s\,L \perp O_g\,B'$. Then :—

$O_s\,L = B\,I = B'\,V' + V\,i - V\,B$;
$O_g\,L = O_g\,B' - L\,I - B'\,I = R_g - R_s - B'\,I$;

$$\text{Tan}\, s = O_s\,L/O_g\,L;$$
$$\Delta_g = \Delta - \Delta_s\text{; and}$$
$$d = R_g - R_s - (O_g\,L) \sec s.$$

See letter from Wm. R. Dunham, Jr., Eng Record, 1906, Apr 7, p 466.

Changes of Location.

132. In the following, R, T, E, etc, A, V, B, Δ, etc, indicate the given radius, semitan, ext dist, etc, T. C., vertex, C. T., sweep, etc, for the *existing* curv; and R', T', E', etc, A', V', B', Δ', etc, indicate corresponding lengths, points and angles for the *new* curv. In general, *solid* lines, in the Figs, refer to the *existing* curv; *dotted* lines to the *new* curv, or to demonstration of formulas.

Tangents Unchanged.

133. Fig 47. Change of curv joining two given tans (Δ and V constant); requiring change of given R, T and E ($E = V\,P$).

Here, $T\ (= A\,V) = R \tan(\Delta/2)$; $T'\ (= A'\,V) = R' \tan(\Delta/2)$; $T - T' = AA'$; $E\ (= V\,P) = R\,\text{exsec}(\Delta/2) = T \tan(\Delta/4)$; $E'\ (= V\,P') = R'\,\text{exsec}(\Delta/2) = T' \tan(\Delta/4)$; $E - E' = P\,P'$; $R - R' = (O\,O') \cos(\Delta/2)$.

Given, $B\,B'$. Reqd R', $A\,A'$ and $V\,V'$. Draw $O'\,G \parallel A\,K$; and $V'\,e \parallel B\,B'$. Produce radius $O\,B$ to meet tan $A\,K$ in K.

$$B\,B' = B\,K - B'K = R \text{ exsec } \Delta - R' \text{ exsec } \Delta$$
$$= (R - R') \text{ exsec } \Delta.$$

$$\therefore R - R' = \frac{B\,B'}{\text{exsec } \Delta}; \quad \text{and } R' = R - \frac{B\,B'}{\text{exsec } \Delta}.$$

$$A\,A' = G\,O' = G\,O \tan \Delta = (R - R') \tan \Delta$$
$$= \frac{B\,B'}{\text{exsec } \Delta} \tan \Delta = \frac{B\,B'}{\tan(\Delta/2)}$$

$$V\,V' = \frac{V'\,e}{\sin \Delta} = \frac{B\,B'}{\sin \Delta}.$$

138. Each tan shifted, parallel with itself. Δ constant. R constant. Curv point, A, and tan point, B, changed.

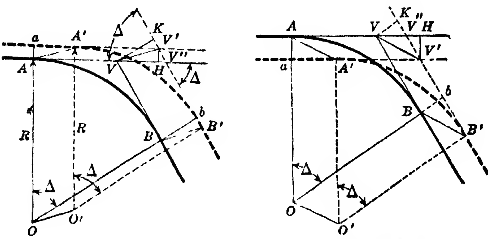

Fig. 51. Fig. 52.

(1) Fig 51. **Both tans shifted** outward, as shown, or both inward

Let tan $A\,V$ be shifted thru dist $A\,a$; tan $V\,B$ thru dist $B\,b$.

Then $A\,A'$, $B\,B'$, $O\,O'$ and $V\,V'$ are equal and parallel.

Required $a\,A'$ and $b\,B'$.

Let V'' be the intersection of $A\,V$ and $V'\,B'$.

Draw $V\,K \parallel B\,b$, and $V'\,H \parallel A\,a$. Then :—

$$a\,A' = V\,H = V\,V'' - V''\,H = \frac{B\,b}{\sin \Delta} - \frac{A\,a}{\tan \Delta}.$$

$$b\,B' = K\,V' = K\,V'' - V''\,V' = \frac{B\,b}{\tan \Delta} - \frac{A\,a}{\sin \Delta}.$$

139. (2) Fig 52. **One tan shifted inward, the other outward.**

Let one of the shifts, $A\,a$, be considered *negativ*. Then $V''\,H$ and $V''\,V'$ are negativ; and

$a\,A' = V\,V''$ *plus* $V''\,H$; $\qquad b\,B' = K\,V''$ *plus* $V''\,V'$.

Divergent tangents, $V z$ **and** $V' z'$, **forming angle,** a.

140. Figs 53, 54, 55. **Tangents intersect in tangent point, B.**

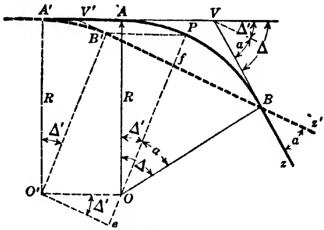

Fig. 53.

Fig 53. (1.) **R constant;** A shifted; new tan point, B'. Given curv $A\ B$, radius, R, and angles, Δ and a. $\Delta' = \Delta \pm a$.*

Required dist $A\ A'$.

Make angle $A\ O\ P = \Delta'$, and thru O, draw $e\ P$ to curv $A\ B$ at P, making $O\ e = P\ f = R$ vers a. Join $O\ O'$ and $e\ O'$. Then :—

$$\mathbf{A\ A'} = O\ O' = \frac{O\ e}{\sin \Delta'} = R\frac{\text{vers } a}{\sin \Delta'}.$$

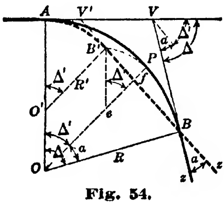

Fig. 54.

141. Fig 54. (2.) **A constant;** R changed; new tan point, B'.

Required, R'.

Note. In order that the tans shall intersect in B, we must have $R' < R$. In order that A shall remain constant, $V'\ B'$ must meet $A\ V$ at a point, V', in *advance* of A. a = angle, $z\ B\ z'$, betw the two tans. $\Delta' = \Delta - a$.

Make $A\ O\ P = \Delta'$, and draw $O\ P$, intersecting curv, $A\ B$, in P. Draw $B'\ e \parallel O\ A$. Then :—

$$\mathbf{R} - \mathbf{R'}\ (= O\ O') = B'\ e = \frac{P\ f}{\text{vers } \Delta'} = R\frac{\text{vers } a}{\text{vers } \Delta'};$$

$$R' = R\left(1 - \frac{\text{vers } a}{\text{vers } \Delta'}\right).$$

*In Fig 53, a is negativ, and $\Delta' = \Delta - a$. If, as in Fig 55, V is betw A and V', a is positiv, and $\Delta' = \Delta + a$.

142. Fig 55 (3.) **B constant; *A* shifted; *R* changed.**
Required, R' and dist, $A\,A'$.

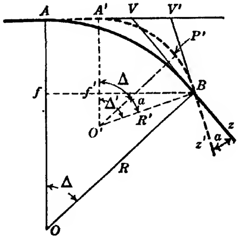

Fig. 55.

Draw $B\,f \perp O\,A$, and $O'\,P' \parallel O\,B$. Then

$$A\,f = A'\,f' = R \text{ vers } \Delta = R' \text{ vers } \Delta'.$$

$$\therefore \mathbf{R'} = R\,\frac{\text{vers } \Delta}{\text{vers } \Delta'};$$

$$\mathbf{A\,A'} = B\,f - B\,f' = R \sin \Delta - R' \sin \Delta'.$$

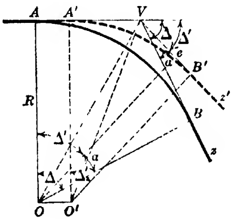

Fig. 56.

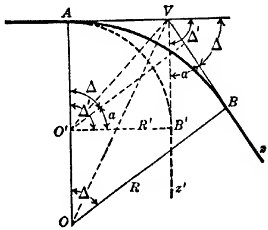

Fig. 57.

Figs 56 and 57. **Tangents intersect in vertex, V.**

143. Fig 56 (1.) **R constant;** *A* shifted; new tan point, B'.
Given, R, Δ and a.
Required, shift, $A\,A'$, for A.

$$A\,V = R \tan(\Delta/2); \quad A'\,V = R \tan(\Delta'/2);$$

$$\therefore \quad \mathbf{A\,A'} = A\,V - A'\,V = R\,[\tan(\Delta/2) - \tan(\Delta'/2)].$$

144. Fig 57 (2). **A constant;** *R* changed; new tan point, B'.
R' may be either greater or less than R.
Given, R, Δ and a.
Required, R'.

$$A\,V = R \tan(\Delta/2) = R' \tan(\Delta'/2);$$

$$\therefore \mathbf{R'} = \frac{A\,V}{\tan(\Delta'/2)} = R\,\frac{\tan(\Delta/2)}{\tan(\Delta'/2)}.$$

Divergent tangents, $V z$ **and** $V' z'$**, forming angle,** a.

140. Figs 53, 54, 55. **Tangents intersect in tangent point, B.**

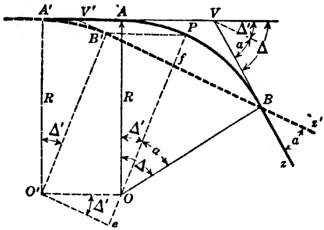

Fig. 53.

Fig 53. (1.) **R constant;** A shifted; new tan point, B'. Given curv $A\ B$, radius, R, and angles, Δ and a. $\Delta' = \Delta \pm a$.*

Required dist $A\ A'$.

Make angle $A\ O\ P = \Delta'$, and thru O, draw $e\ P$ to curv $A\ B$ at P, making $O\ e = P\ f = R$ vers a. Join $O\ O'$ and $e\ O'$. Then :—

$$\mathbf{A\ A'} = O\ O' = \frac{O\ e}{\sin \Delta'} = R \frac{\text{vers } a}{\sin \Delta'}.$$

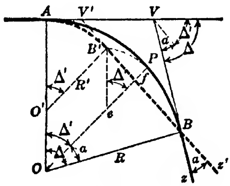

Fig. 54.

141. Fig 54. (2.) **A constant;** R changed; new tan point, B'.

Required, R'.

Note. In order that the tans shall intersect in B, we must have $R' < R$. In order that A shall remain constant, $V'\ B'$ must meet $A\ V$ at a point, V', in *advance* of A. a = angle, $z\ B\ z'$, betw the two tans. $\Delta' = \Delta - a$.

Make $A\ O\ P = \Delta'$, and draw $O\ P$, intersecting curv, $A\ B$, in P. Draw $B'\ e \parallel O\ A$. Then :—

$$\mathbf{R} - \mathbf{R}'\ (= O\ O') = B'\ e = \frac{P\ f}{\text{vers } \Delta'} = R \frac{\text{vers } a}{\text{vers } \Delta'};$$

$$R' = R \left(1 - \frac{\text{vers } a}{\text{vers } \Delta'}\right).$$

*In Fig 53, a is negativ, and $\Delta' = \Delta - a$. If, as in Fig 55, V is betw A and V', a is positiv, and $\Delta' = \Delta + a$.

$$s = \Delta/2 + (s - g)/2; \qquad g = \Delta - s;$$
$$\mathbf{R}_s = T_s/\tan s; \qquad \mathbf{R}_g = T_g/\tan g.$$

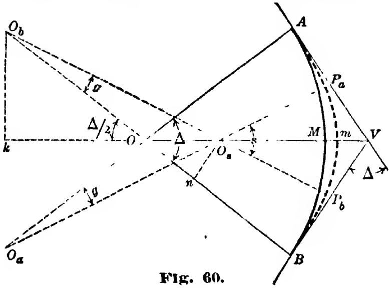

Fig. 60.

147. Figs 60-61. Given, a simple curv, $A\,M\,B$, joining two tangents, $A\,V$ and $V\,B$; Retaining the same tans, it is reqd to **substitute a three-center compound curv.**

148. Fig 60. **A. Retaining A and B.** Compound curv, $A\,P_a\,m\,P_b\,B$.

Let $R = O\,A = O\,M = O\,B$ = radius of simple curv, $A\,M\,B$;
$R_s = O_s\,P_a = O_s\,m = O_s\,P_b < R$;
$R_g = O_a\,A = O_b\,B > R$;
$s = P_a\,O_s\,P_b$; $\quad g = A\,O_a\,P_a = B\,O_b\,P_b$;
$\Delta = A\,O\,B = s + 2\,g$ = sweep of simple curv, $A\,M\,B$;
$M\,m$ = dist betw mid points of the two curvs

Produce $V\,O$ to k, and draw $O_b\,k \perp V\,K$. Then

$$O_b\,k = O_b\,O\sin(\Delta/2) = (R_g - R)\sin(\Delta/2)$$
$$= O_b\,O_s\sin(s/2) = (R_g - R_s)\sin(s/2);$$

whence :—

$$\text{Sin}\,s/2 = \frac{(R_g - R)\sin(\Delta/2)}{R_g - R_s}; \quad g = \frac{\Delta - s}{2};$$

$$\mathbf{R}_g = \frac{R\sin(\Delta/2) - R_s\sin(s/2)}{\sin(\Delta/2) - \sin(s/2)}$$

Draw $O_s\,n \perp O\,B$. Then

$$O\,O_s = O_s\,n/\sin(\Delta/2) = (R_g - R_s)\sin g/\sin(\Delta/2);$$

and

$$\mathbf{M\,m} = O\,O_s + O_s\,m - O\,M = O\,O_s - (O\,M - O_s\,m)$$
$$= (R_g - R_s)\frac{\sin g}{\sin(\Delta/2)} - (R - R_s).$$

---

*From the equations for sin $(A + B)$, cos $(A + B)$, sin $(A - B)$ and cos $(A - B)$, ¶¶ 15, 16, p 97b, it can be shown that

$$\sin\frac{s - g}{2} = \sin\frac{\Delta}{2} \times \frac{\tan(s/2) - \tan(g/2)}{\tan(s/2) + \tan(g/2)};$$

and, from $T_g = T_s\,\dfrac{\tan(s/2)}{\tan(g/2)}$, ¶ 57 and p 38, ¶ (5), we have

$$\frac{T_g - T_s}{T_g + T_s} = \frac{\tan(s/2) - \tan(g/2)}{\tan(s/2) + \tan(g/2)}$$

149. Fig 61. **B. Retaining the same middle point, M.** Compound curv, $A' P_a M P_b B'$.

Let $R = OA = OM = OB =$ radius of simple curv, AMB;
$R_s = O_s P_a = O_s M = O_s P_b < R$;
$R_g = O_a A' = O_b B' > R$;
$s = P_a O_s P_b$; $g = A' O_a P_a = B' O_b P_b$;
$\Delta = AOB = s + 2g$.

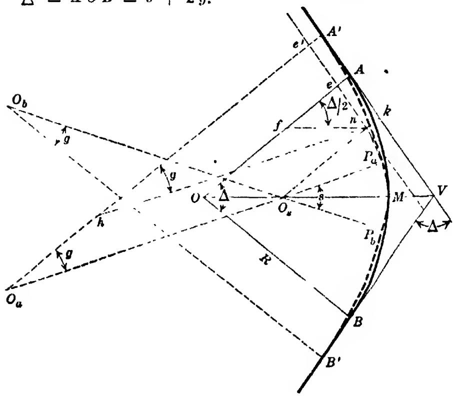

Fig. 61.

In the Fig, produce the curve, $P_b M P_a$, to meet, at n, the line, $O_s k$, $\parallel OA$; and draw $nh \parallel P_a O_a$, and $nf \parallel O_s O$. Then n is a point in the long chord, MA (not drawn), and in the long chord, $P_a A'$ (not drawn); the tan, en, thru n, is $\parallel AV$; and

$$nk = Ae = nf \operatorname{vers}(\Delta/2) = (R - R_s) \operatorname{vers}(\Delta/2)$$
$$= A'e' = nh \operatorname{vers} g = (R_g - R_s) \operatorname{vers} g;$$

whence we have:—

$$\operatorname{vers} g = \frac{nk}{R_g - R_s} = \frac{(R - R_s)\operatorname{vers}(\Delta/2)}{R_g - R_s};$$

$R_g = R_s + (nk/\operatorname{vers} g)$;

$R_s = R - [nk/\operatorname{vers}(\Delta/2)]$.

$\cot(g/2) = \cot(\Delta/4) + (AA'/nk)$; $s = \Delta - 2g$;

$AA' = BB' = kA' - kA = nk\,[\cot(g/2) - \cot(\Delta/4)]$

150. Shifting C.T. along its tangent. Fig 62. Given a compound curv, UPE, joining two tans, UV and VE. Retaining the same tangent-directions, and the given initial radius, R_u, it is desired to make the second branch join the same final tan, VE', as before, but at E', instead of at E.

Required, the new final radius, R_e', and the new distribution of the sweep, Δ, betw the two branches; *i. e.*, the new values (u' and e'), of the sweeps, u and e. The change involvs shifting the C.C. from P to a new point, as P'.

Let y ($= EE'$) be *positiv* when measured *forward* from E, as in Fig 62.

As in Fig 62, let the subscript, e, refer to that branch whose radius, R_e, is to be changed; and let the subscript u refer to the other branch.

Since the tangent-directions are unchanged, we have $\Delta = u + e = u' + e'$; and $u' = u + e - e'$.

In the Fig, produce the u branch, $U P$, to meet, at n, the line, $O_u\, n$, drawn parallel with $O_e\, E$ (n is in any straight line $P E$, $P' E'$, joining either C. C. with the corresponding tan point). Draw $n\, f$, $\parallel$ and $= O_u O_e = R_e - R_u = f E$. Draw $n\, k'$, $\perp$ $O_e\, E$ and $\perp$ $O_e'\, E'$.

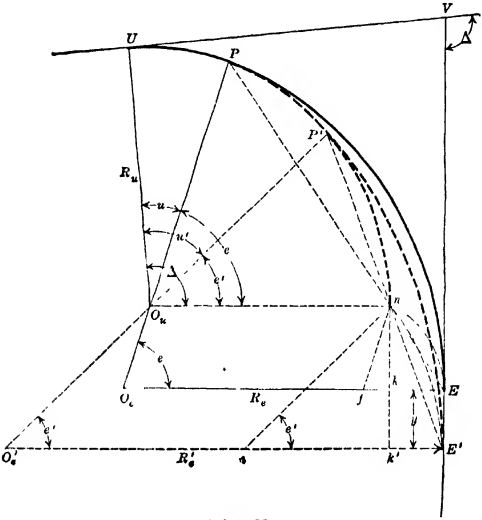

Fig. 62.

(1) Given the change ($= P\, O_u\, P' = u' - u = e - e'$) in the sweeps; reqd R_e' and y ($= E\, E'$). Here we have $e' = P'\, O_e'\, E' = P'\, O_u\, n = \Delta - (u + P\, O_u\, P')$. In the Fig, draw $n\, i$ $\parallel$ and $= O_u\, O_e' = R_e' - R_u$. Then.—

$E'\, k' = (R_e' - R_u)$ vers e' $= E\, k = (R_e - R_u)$ vers e. Hence,

$$\mathbf{R_e'}\ (= O_e'\, E') = O_e'\, i + \frac{E\, k}{\text{vers } e'} = R_u + (R_e - R_u) \text{ vers } e/\text{vers } e';$$

$$\begin{aligned} \mathbf{y}\ (= \mathbf{E\, E'} = n\, k' - n\, k) &= E'\, k' \cot(e'/2) - E\, k \cot(e/2) \\ &= E\, k\ [\cot(e'/2) - \cot(e/2)] \\ &= (R_e - R_u) \text{ vers } e\ [\cot(e'/2) - \cot(e/2)]. \end{aligned}$$

(2) Given R_e'; reqd $P\, O_u\, P'$ ($= u' - u = e - e'$) and y ($= E\, E'$). Here we have:—

$$\text{vers } e' = \frac{E'\, k'}{n\, i} = \frac{E\, k}{n\, i} = \frac{(R_e - R_u) \text{ vers } e}{R_e' - R_u}\ ; \text{ and}$$

$$\mathbf{P\, O_u P'} = e - e';\ u' = u + P\, O_u P'.$$

$\mathbf{y}$ ($= \mathbf{E\, E'}$) as above.

(3) Given y ($= E\,E'$); reqd $P\,O_u P'$ ($= e - e'$) **and** R_e'.

Since (see above) y ($= E\,E'$) $= E\,k\,[\cot(e'/2) - \cot(e/2)]$, we have:—

$$\frac{y}{E\,k} = \cot(e'/2) - \cot(e/2)\text{ ; and } \cot(e'/2) = \cot(e/2) + \frac{y}{E\,k}$$

$$= \cot(e/2) + \frac{y}{(R_e - R_u)\text{ vers }e}.\quad\text{Then :—}$$

$P\,O_u\,P'$ and R_e' may be found as above.

Plus and minus signs. See p 917, ¶ 69.

	E' beyond E (y positiv)		E' betw E and V (y negativ)	
	$R_e > R_u$ (Fig 62)	$R_e < R_u$	$R_e > R_u$	$R_e < R_u$
$P\,O_u\,P'$	positiv	negativ	negativ	positiv
e'	$< e$	$> e$	$> e$	$< e$
R_e'	$> R_e$	$> R_e$	$< R_e$	$< R_e$

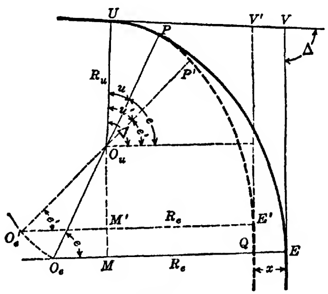

Fig. 63.

151. Fig 63. Given a compound curv, $U\,P\,E$, joining the tans, $U\,V$ and $V\,E$. It is required **to shift the final tangent,** $V\,E$, parallel with itself, to the new position, $V'\,E'$, retaining the original radii, R_u and R_e. The change involvs shifting the C. C. from P to a new point, as P'.

As in Fig 63, let the subscript, e, refer to that branch which joins the tan, $V\,E$, to be shifted; and let the subscript, u, refer to the other branch.

Since $V\,E$ and $V'\,E'$ are parallel, we have $\Delta = u + e = u' + e'$, or $u' = u + e - e'$.

Given e, R_e, R_u and the shift, x ($= E\,Q$) of the tan (call x *positiv* when measured *inward* from E, as in Fig 63);

Required the new distribution of the sweep, Δ, betw the two branches; *i. e.*, the new values, (u' and e',) of the sweeps, u and e.

Draw $O_u M \perp O_e E$ and $\perp O_e' E'$. Then

(1) $O_e' M' = R_e - E' M' = O_e' O_u \cos e' = (R_e - R_u) \cos e'$;
(2) $O_e M = R_e - E M = O_e O_u \cos e = (R_e - R_u) \cos e$.

Subtracting (2) from (1), we have

$E M - E' M' (= E Q) = x = (R_e - R_u) (\cos e' - \cos e)$

and

$$\cos e' = \cos e + \frac{x}{R_e - R_u}; \quad u' = \Delta - e'.$$

Plus and minus signs ($\Delta < 90°$). See ¶ 69.

$V' E'$ *inside* of $V E$ (x positiv)		$V' E'$ *outside* of $V E$ (x negativ)	
$R_e > R_u$ (Fig 63)	$R_e < R_u$	$R_e > R_u$	$R_e < R_u$
$e' < e$	$e' > e$	$e' > e$	$e' < e$

152. Figs 64. Given a compound curv, $U P M E$, joining the tans, $U V$ and $V E$. It is desired that the **direction of the tangent V E shall be changed** to $V' E$, $V' E$ forming, with $V E$, the angle, $a = V E V'$, and passing thru E.

Retaining the first radius, R_u, and the curv point, U, it is required to find the new radius, R_e', replacing R_e, and the changes in u and e. The change involvs shifting the C.C. from P to a new point, as P'.

Δ, Δ'	=	compound curv sweep for old and new curv respectivly.
R_u	=	initial rad (unchanged in this problem).
R_e, R_e'	=	final radius for old and new curv respectivly.
u, u'	=	sweep of R_u for old and new curv respectivly.
e	=	sweep of R_e.
e'	=	sweep of R_e'
a	=	$V E V'$

Then $\Delta = u + e = \Delta' \pm a$; $\quad u = \Delta - e = \Delta' \pm a - e$
$\quad e = \Delta - u = \Delta' \pm a - u$

$\Delta' = u' + e' = \Delta \pm a$; $\quad u' = \Delta' - e' = \Delta \pm a - e'$
$\quad e' = \Delta' - u' = \Delta \pm a - u'$.

Required, R_e', Δ', e', and u'.

153. (1) Given Δ, a, u, e, R_u and R_e. Graphic method.

From E, draw a line in the direction, $E O_e' \perp V' E$. On this line, measure $E H = R_u$. Join $H O_u$. Bisect $H O_u$ in h, and draw $h O_e' \perp H O_u$, to meet $E H$ (produced, if necessary) in O_e'. Then, $R_e' = R_u \pm H O_e' = R_u \pm O_u O_e' = E H \pm H O_e' = E O_e'$.

From O_e', thru O_u, draw $O_e' P'$, to intersect the U branch, $U P$ (produced, if necessary), in the new C.C. at P'. Then

$e' = P' O_e' E$; $\quad u' = U O_u P'$.

When	Fig	We have R_u	O_e & O_e' in	Foci	Maj axis
$R_e > R_u$	a,	$= O_e' E - O_e' O_u$ $= O_e E - O_e O_u$ $= R_e - (R_e - R_u)$	hyperbola	O_u, E	$m n = R_u$
$R_e < R_u$	b,	$= O_e' E + O_e' O_u$ $= O_e E + O_e O_u$ $= R_e + (R_u - R_e)$	ellipse	O_u, E	$m n = R_u$

154. Figs 64. (2) Given Δ, a, u, e, R_u, R_e, U V and E V.

Or, if $U V$ and $E V$ are not given, we have:—

U V $\sin \Delta = R_u \operatorname{vers} \Delta + (R_e - R_u) \operatorname{vers} e$; see eq (74).
E V $\sin \Delta = R_e \operatorname{vers} \Delta - (R_e - R_u) \operatorname{vers} u$; see eq (72).

$EV' = EV \cdot \sin\Delta / \sin\Delta'$; $VV' = EV \cdot \sin a / \sin\Delta'$;
$UV' = UV \pm VV'$;

$$\operatorname{Tan}\frac{e'}{2} = \frac{UV' \sin\Delta' - R_u \operatorname{vers}\Delta'}{EV' + UV' \cos\Delta' - R_u \sin\Delta'}, \text{ See eq (77)};$$

$u' = \Delta' - e' = \Delta \pm a - e'$;
$R_e' \sin e' = EV' + UV' \cos\Delta' - R_u \sin\Delta' + R_u \sin e'$, See Eq (78);
$P\,O_u\,P' = \pm (e - e' \pm a) = \pm (u' - u)$.

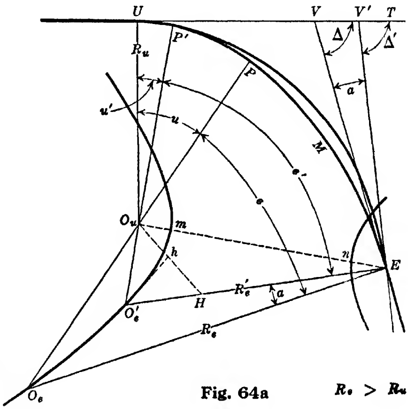

Fig. 64a $R_e > R_u$

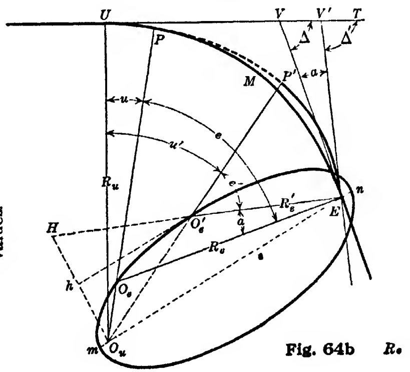

Fig. 64b $R_e < R_u$

When (as in Figs 64) $UV' > UV$, then $\Delta' > \Delta$, and $R_e' < R_e$: and vice versa. This affects the signs (+ and −) of the other values.

RESURVEY OF CURVS

To find the sharpness, D, of an existing curv.

155. Fig 65. Vertex, V, accessible, and directions of tans, VA and VB, given. Required, radius, R (or sharpness, D); A and B.

With the inst at V, measure Δ; and from either tan, lay off angle, BVP or $AVP = (180° - \Delta)/2$. Measure the external, $E = VP$, from V to cen line of existing track. Then we have :—

$R\ (= OA = OB) = E/\text{exsec}(\Delta/2)$;

$T\ (= AV = VB) = E/\tan(\Delta/4) = R\tan(\Delta/2)$;

$\sin(D/2) = 50/R$.

Approx, we have $D = 5730/R$.

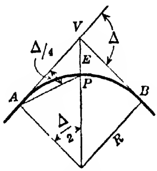

Fig. 65.

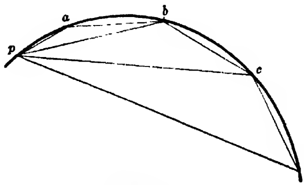

Fig. 66.

156. Fig 66. Vertex, V (not shown), **inaccessible.**

Set up over a point, as p, in the center line of the curv, preferably at or near either end; and lay off and measure peripheral angles, apb, bpc, etc., each subtended by a unit chain (as ab, bc, etc.), on the curv. The average of these angles may be taken as (approx) the peripheral angle, $D/2$, of the curv; and twice $(D/2) = D$ as the sharpness.*

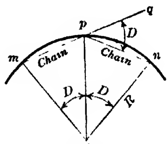

Fig. 67.

157. Fig 67. Or set over any point, p, in center line of track. Measure one chain, $pm = pn$, in each direction, to m and to n, also in center line. Measure angle $qpn = D$.*

*In all such work, the entire curv should be covered as thoroly as practicable, the method being repeated, over different portions of the curv, and an average taken; for, in curvs which hav been used for some time, the curvature is frequently found to vary from point to point, the track having been thrown out of true by traffic, and perhaps relined by eye without reference to center stakes.

158. By middle ordinates. Fig 68. In any circle,

$$(2\,R - m)m = (c/2)^2.$$

Approximately, $2\,R\,m = (c/2)^2$;

or approx, $R = \dfrac{c^2/4}{2\,m} = \dfrac{c^2}{8\,m}$.

Hence, if a cord, of any given length, c, subtending a small sweep, be stretcht betw two points, n and p, on the inner side of the head of the outer rail, and if its mid ord, m, be measured, to the rail head, we have:—

$R = (c^2/8\,m)$ — half the gage.

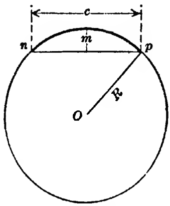

Fig. 68.

Usually the half gage may be neglected.

Then $\sin(D/2) = 50/R$; or, approx, $D = 5730/R$.

If the cord be 100 ft long (= one chain length), and the mid ord m, in ft, measured, D may be taken at once from table, pp 898-9.*

159. Conversely, **to find the mid ord, M** ins **or** m ft, corresponding to any given length of cord, c, in feet, and to any given sharpness, D, or radius, R, we have (approx)

M, ins, $= 12\,m = 12\,c^2/8\,R = 1.5\,c^2/R$.

Thus, with a 30-ft rail (c = approx 30 ft), on a 3° curv (R = 1910 ft), we have, approx:— $M = 1.5 \times 900/1910 = 0.707$ inches.

Again, (approx) $c = \sqrt{8\,m\,R} = \sqrt{8\,m\,5730/D} = 214\,\sqrt{m/D}$.

If, now, we make M = mid ord in ins $= 12\,m = D$, in degrees, or $m = D/12$, we have, approx:—

$$c = \sqrt{\frac{8\,D}{12}\,.\,R} = \sqrt{\frac{8\,D}{12}\,.\,\frac{5730}{D}} = \sqrt{3820} = 61.81 \text{ ft.}$$

Hence, with a cord, c, 61.81 (say 62) ft long, we have:—

M = mid ord in ins = sharpness, D, of curv in degrees.* Compare ¶ 178.

160. Fig 69. From any point, as a (preferably a joint), on the inner or gage side of the outer rail, sight to another such point, as b, such that the line of sight, $a\,b$, is tangent to the gage side of the inner rail, as at p.

*In all such work, the entire curv should be covered as thoroly as practicable, the method being repeated, over different portions of the curv, and an average taken; for, in curvs which hav been used for some time, the curvature is frequently found to vary from point to point, the track having been thrown out of true by traffic, and perhaps relined by eye without reference to center stakes.

Then, for the mid ord to the chord, $a\,b$, we have $p\,p' = G =$ gage.

Let l = rail-length, in ft; N = number of rail lengths in arc, $a\,p'\,b$. Then $N\,l$ = arc, $a\,p'\,b$, in ft.

Let δ = angle, $a\,O\,b$; C = chord, $a\,b$; R' = outer-rail gage-side radius; R = center-line radius; D = center-line sharpness.

Measure $C = a\,b$; or count N, find $N\,l$, and (generally near enough) assume chord, $a\,b$ = arc, $N\,l$. Then:

$\tan(\delta/4) = \tan p'\,a\,p = 2\,G/C$; $R' = C/2\sin(\delta/2)$;
$R = R' - (G/2)$; $\sin(D/2) = 50/R$; or, approx, $D = 5730/R$.

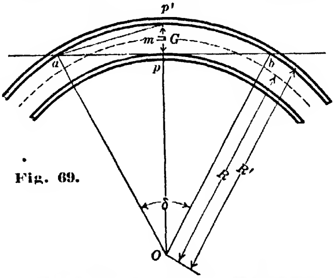

Fig. 69.

Classification of Resurvey Cases.

161. As to the choice of method of procedure, resurvey cases may be classified as follows:—

A. Vertex, *V*, accessible; short curvs;
B. Vertex, *V*, inaccessible;
  1 Curvs of moderate length;
  2. Long curvs.

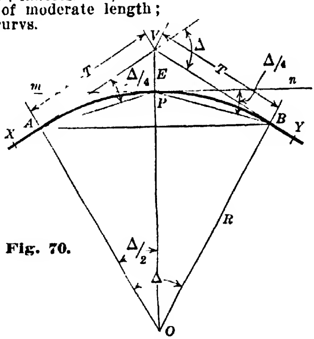

Fig. 70.

Procedure.

A. Vertex, V, accessible; short curvs.

162. Fig 70. Locate vertex, *V*, thus: with inst. at a point, *X*, on a tangent, say 50 ft back from the curv point, *A*, backsight along the tan, and plunge telescope, sighting toward *V*. Doing the same at *Y*, on the other tan, *V B*, we find the intersection, *V*, of the two tans.

Find Δ, *E*, *R*, *D* and *T* as in ¶ 155.

Then,

L (= curv length, $A\ P\ B$, in unit chains) $= \Delta/D$.

Locate the curv points, A and B, by laying off $T = V A = V B$, from V, or by laying off $L/2$, in ft, along cen line of curv, from P. $L/2$, in unit chains, $= \Delta/(2\,D)$; $L/2$, in ft. $= 50\ \Delta/D$.

With inst at P, lay off right angles, $V P m$ and $V P n$, locating the tan, $m\,n$; and verify angles $m P A = n P B = \Delta/4$; or

With inst at A and at B, verify angle $V A B = V B A = \Delta/2$, or $V A P = V B P = \Delta/4$.

If the track has shifted materially at P, giving a false value of E, the foregoing equations will of course give false values of R and D. Compare the value of D, so found, with the value recorded. If the track has shifted betw P and A or betw P and B, the measurement of $L/2$ from P, as above, may give false positions for A and B. The discrepancies must be adjusted, according to circumstances.

Run the new curv, marking it temporarily. Observe what amount of throw, and in which direction, is required at each point. Re-adjust, if necessary, and drive stakes to mark the final location

B. Vertex, V, inaccessible.

Curvs of moderate length.

a. By Trial Curv. Fig. 71.

163. Given, the sharpness, D, of an old curv, whose original position was $A\ B$, and the directions of its tans, $A\ V$ and $V\ B$. Required, Δ and the positions of the T.C. (A) and C.T. (B)

Let A'' be the supposed position of the T.C., or a point, near the T.C., on the tan or on the tan produced. Set over A'', and begin running a trial curv, $A''\,m$, of the given sharpness, D, marking the 100-ft chain points temporarily.

If A'' is materially distant from the T C. (A), as in Fig 71*, the trial curv, $A''\,m$, will soon be found deviating seriously, as at m, from the old track, $A\ B$. Measure the distance, $m\,s$, betw the trial curv, $A''\,m$, and the cen line, $A\ B$, of the old track. Then, for the shift, $A''\,A$, reqd for the T.C., we have :—

$$A''A = m\,n = \text{(approx)}\ m\,n'\ ^* = \frac{m\,s}{\sin \Delta_m}\ ^\dagger,$$

where Δ_m (or $m\,\dagger$) = sweep of trial curv betw A'' and m.*

Let $A''\,A'$ represent the approx value thus found for the shift, $A''\,A$. Move inst to A', and re-run the trial curv, with D as before, taking transit points, T_1, T_2, etc., at preferably equal dists of say 500 ft. From each transit point, locate a short line, as $T_3\,x$, parallel with the original tan, $A\ V$, marking said line with a nail, as at x.

Run the trial curv, $A'\,T_3$, thru a sweep, $s\dagger$, to a point, as T_4, where its final tan, $v'\,T_4$, is supposed to be parallel with that, $V\,B$, of the old curv, $A\ B$. Thru T_4 run a line, $T_4\,u$, parallel with $V\,B$, and measure the angle, $t\dagger$, betw $T_4\,u$ and $v'\,T_4$ produced. Then :—

$$\Delta = s \pm t.\dagger$$

*To facilitate illustration, the deviations, in Fig 71, are grossly exaggerated. In practice, the tans of the two curvs, at m and at s, would be approx parallel.

†In Fig 71, the angles, Δ_m, Δ_s and Δ_t are designated as m, s and t, respectivly, to avoid overcrowding.

Locate the terminus, B', of the trial curv, $A' B'$, accordingly. The tan, $V' B'$, is then parallel with the tan, $V B$, thru B; and angle $F V' B' = F V B = \Delta$.

Measure the dist, $B' e$, from B' to the cen line of the old track.* Then, for the shift, $A' A = B' B$, still reqd, to bring A' and B' into their proper positions, A and B, respectivly, we have:—

$$B' B = \frac{B' e}{\sin \Delta} \text{ *}$$

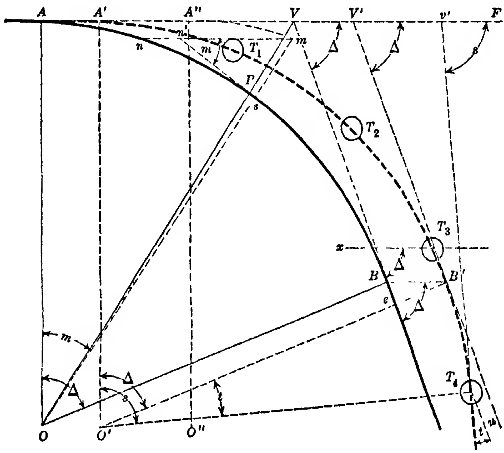

Fig. 71.

Each of the transit points, T_1, T_2, etc, is also to be shifted thru a dist $= B' B$, in the direction, $T_3 x$, parallel with the original tan, $A V$; the entire curv being thus shifted, in that direction, thru a dist $= B' B$.

If the trial curv, $A' B'$, had fallen inside (instead of outside) the existing track, this shifting of the trial curv would of course have been in the opp direction.

From each transit point, as thus shifted, and from A, the curv may now be re-run in each direction, coinciding nearly with the existing track. The max dist, from inst to stake, will be half the dist betw transit points.

---

*To facilitate illustration, the deviations, in Fig 71, are grossly exaggerated. In practice, the tans of the two curvs, at m and at s, would be approx parallel.

Then,

L (= curv length, $A\,P\,B$, in unit chains) $= \Delta/D$.

Locate the curv points, A and B, by laying off $T = V\,A = V\,B$, from V, or by laying off $L/2$, in ft, along cen line of curv, from P $L/2$, in unit chains, $= \Delta/(2\,D)$; $L/2$, in ft. $= 50\ \Delta/D$.

With inst at P, lay off right angles, $V\,P\,m$ and $V\,P\,n$, locating the tan, $m\,n$; and verify angles $m\,P\,A = n\,P\,B = \Delta/4$; or

With inst at A and at B, verify angle $V\,A\,B = V\,B\,A = \Delta/2$, or $V\,A\,P = V\,B\,P = \Delta/4$.

If the track has shifted materially at P, giving a false value of E, the foregoing equations will of course give false values of R and D. Compare the value of D, so found, with the value recorded. If the track has shifted betw P and A or betw P and B, the measurement of $L/2$ from P, as above, may give false positions for A and B. The discrepancies must be adjusted, according to circumstances.

Run the new curv, marking it temporarily. Observe what amount of throw, and in which direction, is required at each point. Readjust, if necessary, and drive stakes to mark the final location

B. Vertex, V, inaccessible.

Curvs of moderate length.

a. By Trial Curv. Fig. 71.

163. Given, the sharpness, D, of an old curv, whose original position was $A\,B$, and the directions of its tans, $A\,V$ and $V\,B$. Required, Δ and the positions of the T.C. (A) and C.T. (B)

Let A'' be the supposed position of the T.C., or a point, near the T.C., on the tan or on the tan produced. Set over A'', and begin running a trial curv, $A''\,m$, of the given sharpness, D, marking the 100-ft chain points temporarily.

If A'' is materially distant from the T.C. (A), as in Fig 71*, the trial curv, $A''\,m$, will soon be found deviating seriously, as at m, from the old track, $A\,B$. Measure the distance, $m\,s$, betw the trial curv, $A''\,m$, and the cen line, $A\,B$, of the old track. Then, for the shift, $A''\,A$, reqd for the T.C., we have :—

$$A''\,A = m\,n = \text{(approx)}\ m\,n'\,^* = \frac{m\,s\ \dagger}{\sin \Delta_m},$$

where Δ_m (or m †) = sweep of trial curv betw A'' and m.*

Let $A''\,A'$ represent the approx value thus found for the shift, $A''\,A$. Move inst to A', and re-run the trial curv, with D as before, taking transit points, T_1, T_2, etc., at preferably equal dists of say 500 ft. From each transit point, locate a short line, as $T_3\,x$, parallel with the original tan, $A\,V$, marking said line with a nail, as at x.

Run the trial curv, $A'\,T_3$, thru a sweep, s†, to a point, as T_4, where its final tan, $v'\,T_4$, is supposed to be parallel with that, $V\,B$, of the old curv, $A\,B$ Thru T_4 run a line, $T_4\,u$, parallel with $V\,B$, and measure the angle, t†, betw $T_4\,u$ and $v'\,T_4$ produced. Then :—

$$\Delta = s \pm t.\dagger$$

*To facilitate illustration, the deviations, in Fig 71, are grossly exaggerated. In practice, the tans of the two curvs, at m and at s, would be approx parallel.

†In Fig 71, the angles, Δ_m, Δ_s and Δ_t are designated as m, s and t, respectivly, to avoid overcrowding.

165. Fig 73. But points on the final curv, $A_1 B_1$, may be located **by simple measmt from the curv, A B,** thus:—

Required, to find (approx) the dist, $x x_1$, betw the two curvs, $A B$ and $A_1 B_1$, measured ∥ with the central radius, $O_1 P_1$.

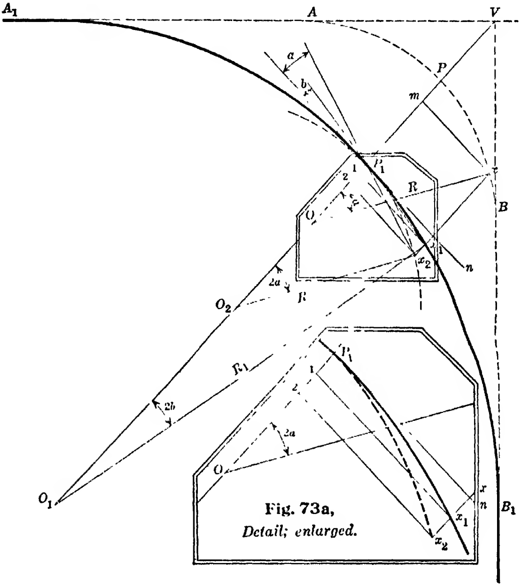

Fig. 73a, *Detail; enlarged.*

Fig. 73.

In Fig 73 (grossly exaggerated; see detail, Fig 73a), let the dotted curv, $P_1 x_2$ represent a curv having the same radius, R, as curv, $A B$, but passing thru the mid point, P_1, of curv $A_1 B_1$; and let $x_2 x_1$ be the dist (parallel with $P P_1$) from a given point, x_2, on curv $P_1 x_2$, to a required point, x_1, on the reqd curv, $A_1 B_1$. Draw $x_1 1$ and $x_2 2$, parallel to the tan, $P_1 n$, thru P_1. Then:—

$$x_2 x_1 = P_1 2 - P_1 1 = P m - P_1 1$$
$$= R \text{ vers } 2a - R_1 \text{ vers } 2b; \text{ where } a = n P_1 x_2,$$
$$\text{and } b = n P_1 x_1;$$

and the dist, $x x_1$, from the curv, $A B$, in the same direction, to the reqd point, x_1, on the final curv, $A_1 B_1$, is

$$x x_1 = x x_2 - x_2 x_1 = P P_1 - (R \text{ vers } 2a - R_1 \text{ vers } 2b.)$$

This method is sufficiently approx in practice, notwithstanding that the measurements, given by the equations, are parallel to $P P_1$, instead of being radial to either curv. As this divergence increases (with the dist of the point, x_1, from P_1) the dist, $x x_1$, betw the two curvs, diminishes.

Then,

L (= curv length, $A\,P\,B$, in unit chains) = Δ/D.

Locate the curv points, A and B, by laying off $T = V\,A = V\,B$, from V, or by laying off $L/2$, in ft, along cen line of curv, from P $L/2$, in unit chains, = $\Delta/(2\,D)$; $L/2$, in ft. = $50\ \Delta/D$.

With inst at P, lay off right angles, $V\,P\,m$ and $V\,P\,n$, locating the tan, $m\,n$; and verify angles $m\,P\,A = n\,P\,B = \Delta/4$; or

With inst at A and at B, verify angle $V\,A\,B = V\,B\,A = \Delta/2$, or $V\,A\,P = V\,B\,P = \Delta/4$.

If the track has shifted materially at P, giving a false value of E, the foregoing equations will of course give false values of R and D. Compare the value of D, so found, with the value recorded. If the track has shifted betw P and A or betw P and B, the measurement of $L/2$ from P, as above, may give false positions for A and B. The discrepancies must be adjusted, according to circumstances.

Run the new curv, marking it temporarily. Observe what amount of throw, and in which direction, is required at each point. Readjust, if necessary, and drive stakes to mark the final location

B. Vertex, V, inaccessible.

Curvs of moderate length.

a. By Trial Curv. Fig. 71.

163. Given, the sharpness, D, of an old curv, whose original position was $A\,B$, and the directions of its tans, $A\,V$ and $V\,B$. Required, Δ and the positions of the T.C. (A) and C.T. (B)

Let A'' be the supposed position of the T.C., or a point, near the T.C., on the tan or on the tan produced. Set over A'', and begin running a trial curv, $A''\,m$, of the given sharpness, D, marking the 100-ft chain points temporarily.

If A'' is materially distant from the T.C. (A), as in Fig 71*, the trial curv, $A''\,m$, will soon be found deviating seriously, as at m, from the old track, $A\,B$. Measure the distance, $m\,s$, betw the trial curv, $A''\,m$, and the cen line, $A\,B$, of the old track. Then, for the shift, $A''\,A$, reqd for the T.C., we have :—

$$A''\,A = m\,n = \text{(approx)}\ m\,n'\,^* = \frac{m\,s\ \dagger}{\sin\Delta_m},$$

where Δ_m (or m †) = sweep of trial curv betw A'' and m.*

Let $A''\,A'$ represent the approx value thus found for the shift, $A''\,A$. Move inst to A', and re-run the trial curv, with D as before, taking transit points, T_1, T_2, etc., at preferably equal dists of say 500 ft. From each transit point, locate a short line, as $T_3\,x$, parallel with the original tan, $A\,V$, marking said line with a nail, as at x.

Run the trial curv, $A'\,T_3$, thru a sweep, s†, to a point, as T_4, where its final tan, $v'\,T_4$, is supposed to be parallel with that, $V\,B$, of the old curv, $A\,B$. Thru T_4 run a line, $T_4\,u$, parallel with $V\,B$, and measure the angle, t†, betw $T_4\,u$ and $v'\,T_4$ produced. Then :—

$$\Delta = s \pm t.\dagger$$

*To facilitate illustration, the deviations, in Fig 71, are grossly exaggerated. In practice, the tans of the two curvs, at m and at s, would be approx parallel.

†In Fig 71, the angles, Δ_m, Δ_s and Δ_t are designated as m, s and t, respectivly, to avoid overcrowding.

$$\begin{aligned}
\text{lat of } d = ad'' &= ab' + bc' + cd' \\
&= ab\cos A + bc\cos B + cd\cos C; \\
aA &= ad'' - d''V - VA \\
&= ad'' - dd''/\tan\Delta - R\tan(\Delta/2).
\end{aligned}$$

(For dd'', see below. R = radius of existing curv).

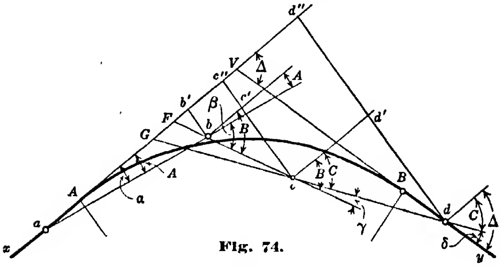

Fig. 74.

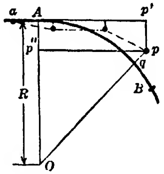
Departures (dists normal to the latitudes); for finding dist dB and location of point, B :—

$$\begin{aligned}
\text{dep of } d = dd'' &= bb' + cc' + dd' \\
&= ab\sin A + bc\sin B + cd\sin C; \\
dB &= dV - VB \\
&= dd''/\sin\Delta - R\tan(\Delta/2).
\end{aligned}$$

Fig. 75.



"Throw"

169. Fig 75. (For curvs with spirals, see end of this ¶.) Having thus, by means of the traverse, ¶¶ 166-168, Fig **74**, found the curv point, A, and tan point, B, the several traverse pts may be used for locating, by simple measurement, as many other pts in the curv; thus, Fig 75.— To find the **throw**, or radial dist, $p\,q$, from a given traverse pt, p, to the curv, $A\,B$;

Let $a\,p'$ = lat of p } referd to the origin, a, of the traverse,
$p'\,p$ = dep of p } and found as in ¶ 168.
R = radius, Oq;

Then :—

$$\text{Tan } A\,O\,p = \frac{p\,p''}{O\,p''} = \frac{a\,p' - a\,A}{R - p'\,p};$$

$$O\,p = \frac{p\,p''}{\sin A\,O\,p} = \frac{a\,p' - a\,A}{\sin A\,O\,p};$$

$$p\,q = R - O\,p.$$

If, as in Fig 75, $R < O\,p$, then p must be moved inward. If $R > O\,p$, then p must be moved outward.

Fig 76. For a point, q, in the circular portion, $B\,B_f$, of a spirald curv :— for A, in the foregoing, read A'; and, for $R - p'\,p$, read $R + H - p'\,p$. Then, as above, $p\,q = R - O\,p$.

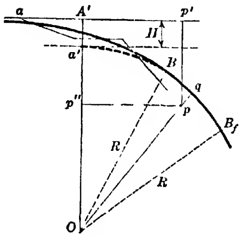


Fig. 76.

Long curvs, requiring compounding.

170. In very long curvs, especially where the track has become much out of line, it is sometimes found unpracticable to approximate satisfactorily to the existing track with a single simple curv. Resort is then had to compounding with curvs of other radii Since long curvs are seldom sharp, the required change of sharpness is seldom more than a few minutes.

The instrument is set over a point as near as may be to the middle point of the curv, and a trial curv is run in each direction, with the sharpness, D, of the existing curv, as ascertained from the records, as estimated, or as assumed

When either trial curv begins to deviate seriously from the existing track, the sharpness is to be slightly increast or diminisht, as may be necessary. This may have to be done several times during the running of the trial curv.

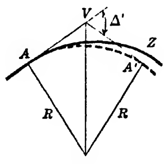

Fig. 77.

Fig 77. Suppose that one of these trial curvs, approaching from the right in the Fig, has thus reacht a point, A', say 500 ft from its destination, which is the curv pt, A, of the existing curv, $Z\,A$. Reqd, the location of A, and the sharpness, D, of the curv, $A'\,A$, which will connect tangentially with the tangent, $A\,V$, at A.

Lay off a tan, $A'\,V$, to its intersection, V, with the tan, $A\,V$, of the existing curv, $Z\,A$. Measure the intersection angle, Δ', at V, and the semitangent, $T = A'\,V = V\,A$.

Then, for the sharpness, D, of the short curv, $A'\,A$, which will complete the line, we have :—

$$R = T \cot (\Delta'/2)\;;\quad D = \text{approx } 5730/R\;;$$

and $V\,A\;(= T) = A'\,V$, measured from V, gives the curv point, A.

171. When double-tracking an existing single-track line, Fig 78, $y\,A\,B\,a\,b\,z$ (centers at O and at o), the sharpness of curvature may be reduced (if there is room on the right of way) by placing the second track, $y'\,A'\,B'$, $B''\,a'\,b'$, $b''\,z'$ (centers at O' and

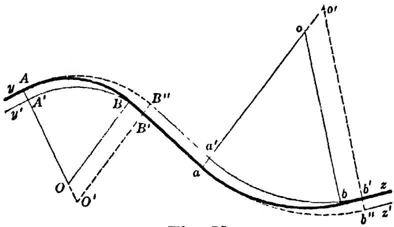

Fig. 78.

at o'), alternately on one and on the other side of the existing single track, constructing also the new curvs, $A\,B''$ and $a\,b''$ (centers at O' and at o'), and eventually removing the old curvs, $A\,B$ and $a\,b$. (Eng News 1913, Oct 23, p 802.)

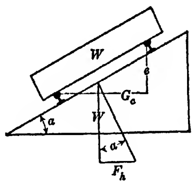
SUPERELEVATION
of Outer Rail on Curvs.

(For transition curvs, see ¶¶ 194, etc.)

Theory.

172. Let a frictionless block, W, sliding forward upon a straight track, upon which the two rails are at the same level, encounter a curv, with superelevation, e, as shown in Fig 79.

Fig. 79.



173. On the curv, its (horizontal) centrifugal force, transversely of the track, is $W\,v^2/R\,g$ (p 354); where W = wt of block; v = its vel, in ft per sec; R = rad of curv, in ft; and g = gravity accel = 32.2 ft per sec per sec.

174. The hor component of its gravitational tendency to slide, transversely of the track, down the inclined plane (*i. e.*, its centripetal force), is $F_h = W \tan a = W\,e/G_c$; where e = superelevation, in ft, and G_c = hor dist, in ft, betw rail centers.

175. In order that the block shall not be shifted laterally, we must have these two forces equal; or $W\,v^2/R\,g = W\,e/G_c$; whence

superel, e, in ft, $= G_c\,v^2/R_g = 0.03106\;G_c\,v^2/R$ .....(114)

For vel, V, in miles per hour, we have:—

superel, e, in ft, $= 0.06680\;G_c\,V^2/R$ ......(115)

Approx, e, in ft $= G_c\,D\,v^2/5730\,g = G_c\,D\,v^2/184{,}500$

$= G_c\,D\,V^2/85{,}768$ ....(116)

176. With standard gage (= 4 ft, 8.5 ins = 4.708 ft), we have, approx, G_e = 4.9 ft, and

	For v, ft/sec;	For V, mi/hour;	
superel, e, in ft	$= 0.1522\ v^2/R$	$= 0.3273\ V^2/R$	
	$= D\ v^2/37{,}652$	$= D\ V^2/17{,}504$	
	$= 0.000\ 026\ 56\ D\ v^2$	$= 0.000\ 057\ 2\ D V^2$	....(117)
superel, E, in ins	$= 1.826\ v^2/R$	$= 3.928\ V^2/R$	
	$= D\ v^2/3{,}137.7$	$= D\ V^2/1{,}458.6$	
	$= 0.000\ 319\ Dv^2$	$= 0.000\ 686\ DV^2$	......(118)

177. For other gages, since the angle, a, Fig 1, is independent of the gage, the superel, e, for a given rad and given vel, is proportional to the gage.

178. Chord, C_o, whose middle ordinate = superelevation. Compare ¶¶ 159, 186 In any circular arc, we have, approx:—

$$\text{chord} = \sqrt{8\ R \times \text{mid ord.}}$$

Hence (Eq 117), we have:

$$C_o = \sqrt{8\ R \times\ 0.000\ 057\ \text{D}\ \text{V}^2} \ldots\ldots\ldots\ldots (119)$$

and, since $R\,D$ = approx 5730. we have, approx:

$$C_o = 1.62\ V = \sqrt{1.219}\ v = 1.1\ v \ldots\ldots\ldots (120)$$

179. Thus, let the speed be 40 miles/hr. For this case, Eq (120) gives C_o = 64.8 ft. Stretch a cord, 64.8 ft long, betw any two pts on the concave side of either rail head. Then, whatever be the sharpness of curvature, the mid ord, from this cord, to the concave side of the same rail head, will be approx the superel reqd, by our equations, for a vel of 40 miles/hr.

Practice.

180. In actual trains, superel has, in view, not only the position of the trucks, transversely of the track (¶ 175), but also the **equilibrium of the car bodies.** Superel counteracts the tendency of the car bodies to swing outward under the action of the centrifugal force.

181. The foregoing equations are based upon the **ideal conditions** of Fig 79; but a railroad car, and, still more so, a train, is a complicated body, made up of many parts which are differently acted upon by diff forces; and the conditions are widely diff from those of Fig 79. Friction, betw wheel tread and top of rail head, causes the first outer wheel of a car to roll forward so that its flange presses against the head of the outer rail; and the resistance of that rail to the wheel's forward motion supplies a centripetal force, additional to that, F_h, of gravity (¶ 174), and wanting in Fig 79; and the action of the two principal forces, upon the following wheels, is complicated by the traction, exerted upon them by preceding portions of the train. See ¶ 36, p 1061. Even if an ideally perfect formula, involving the speed, could be devised, its usefulness would be limited by the fact that but one superel can be given to any piece of track; altho, on most roads, trains must travel at widely diff speeds. Nevertheless, these equations are quite generally used in practice, with modifications to suit special cases.

182. The amount and details of superel are fixt largely by individual judgment (¶¶ 183 to 187). based upon local conditions, by the nature of the traffic, etc. On the score of safety and for the comfort of passengers, the superel is usually adjusted for the *higher* speeds expected; but this may entail heavy work upon long and slow trains; and, where a train stops upon a sharp curv, a high superel causes an objectionable cant in the car bodies.

183. The superel is customarily taken at from 0.5 to 1.0 inch (in some cases, 1.25, 1.5 or even 2 ins) **per degree of sharpness;** with a max total limit of from 4 to 6 (or even 8) inches; speed being reduced where necessary Eq (114) requires a superel of 0.5 inch per deg of sharpness at about 27 miles/hr, 1 inch at about 38 m/h, and 2 ins at about 55 m/h.

184. The common practice (¶ 183) of making the superel proportional to sharpness of curvature, disregards the fact that **high speeds are usually lowered upon sharp curvs.** See ¶ 187.

185. On the New York Central (four tracks) E **max** = **6.5 ins.** For passenger trains on curvs flatter than 1°,

E = 2 ins per deg;

for passenger trains on curvs 1° and sharper,

E = 1 in per deg + 1.5 ins;

for freight trains,

E = 0.75 in per deg.

This gives:

for sharpness	0.25°	0.50°	0.75°	1.00°	1.25°	1.50°	1.75°
E, ins, passenger,	1/2	1	1½	2½	2¾	3	3¼
freight,	3/16	⅜	9/16	¾	15/16	1⅛	1 5/16
for sharpness	**2.00°**	**3.00°**	**4.00°**	**5.00°**	**6.00°**	**8.00°**	**10.00°**
E, ins, passenger,	3½	4½	5½	6½	6½	6½	6½
freight,	1½	2¼	3	3¾	4½	6	6½

186. The Phila. & Reading makes E or e = mid ord of that chord whose length, C_o, = 1.466 V, is the dist run by express trains in one second; E max = 8 inches. Compare ¶¶ 178,179.

187. Other roads use E = 1 inch per deg, plus a quantity beginning with 1 inch for a 1° curv, and diminishing by ⅛ inch for each deg.

This gives

for D =	0	1°	2°	3°	4°	5°	6°	8°	10°
E ins	0	2	2⅞	3¾	4⅝	5½	6⅜	8⅛	10

This takes account of the fact that the fastest running is apt to occur on the easiest curvs. See ¶ 184.

For ordinary practice, the **Am Ry Eng Assn,** Manual, 1915, p 158, recommends superel E = 0.00066 $D\,V^2$. Compare our eq (118) ¶ 176; E max = ordinarily 8 ins.

Cross Section.

188. In single track, superel may be effected, either

(1) by raising the outer rail;	inner rail remains at grade;	car's grav cen raisd $e/2$.
(2) by lowering the inner rail;	outer rail remains at grade;	car's grav cen lowerd $e/2$.
(3) by combining (1) and (2);	center line remains at grade;	car's grav cen maintains elev'n.

The Am Ry Engng Assn, Manual, 1915, p 159, recommends method (1).

Fig. 80.

189. Fig 80. **On double track,** three methods are used;

Plane. Favorable for drainage, and for placing cross-overs and railway and highway-grade crossings;

Saw-tooth. Generally used. Requires cross drains under one of the tracks;

Stept. Permits drainage without cross-drains.

176. With standard gage ($= 4$ ft, 8.5 ins $= 4.708$ ft), we have, approx, $G_e = 4.9$ ft, and

	For v, ft/sec;	For V, mi/hour;	
superel, e, in ft	$= 0.1522\, v^2/R$	$= 0.3273\, V^2/R$	
	$= D\, v^2/37{,}652$	$= D\, V^2/17{,}504$	
	$= 0.000\,026\,56\, D\, v^2$	$= 0.000\,057\,2\, D V^2$	....(117)
superel, E, in ins	$= 1.826\, v^2/R$	$= 3.928\, V^2/R$	
	$= D\, v^2/3{,}137.7$	$= D\, V^2/1{,}458.6$	
	$= 0.000\,319\, D v^2$	$= 0.000\,686\, D V^2$	......(118)

177. For other gages, since the angle, a, Fig 1, is independent of the gage, the superel, e, for a given rad and given vel, is proportional to the gage.

178. Chord, C_o, whose middle ordinate = superelevation. Compare ¶¶ 159, 186 In any circular arc, we have, approx:—

$$\text{chord} = \sqrt{8\, R \times \text{mid ord}}.$$

Hence (Eq 117), we have:

$$C_o = \sqrt{8\, R \times 0.000\,057\,D\,V^2} \quad \ldots\ldots\ldots\ldots (119)$$

and, since $R\,D =$ approx 5730, we have, approx:

$$C_o = 1.62\, V = \sqrt{1.219}\; v = 1.1\, v \quad \ldots\ldots\ldots (120)$$

179. Thus, let the speed be 40 miles/hr. For this case, Eq (120) gives $C_o = 64.8$ ft. Stretch a cord, 64.8 ft long, betw any two pts on the concave side of either rail head. Then, whatever be the sharpness of curvature, the mid ord, from this cord, to the concave side of the same rail head, will be approx the superel reqd, by our equations, for a vel of 40 miles/hr.

Practice.

180. In actual trains, superel has, in view, not only the position of the trucks, transversely of the track (¶ 175), but also the **equilibrium of the car bodies.** Superel counteracts the tendency of the car bodies to swing outward under the action of the centrifugal force.

181. The foregoing equations are based upon the **ideal conditions** of Fig 79; but a railroad car, and, still more so, a train, is a complicated body, made up of many parts which are differently acted upon by diff forces; and the conditions are widely diff from those of Fig 79. Friction, betw wheel tread and top of rail head, causes the first outer wheel of a car to roll forward so that its flange presses against the head of the outer rail; and the resistance of that rail to the wheel's forward motion supplies a centripetal force, additional to that, F_h, of gravity (¶ 174), and wanting in Fig 79; and the action of the two principal forces, upon the following wheels, is complicated by the traction, exerted upon them by preceding portions of the train. See ¶ 36, p 1061. Even if an ideally perfect formula, involving the speed, could be devised, its usefulness would be limited by the fact that but one superel can be given to any piece of track; altho, on most roads, trains must travel at widely diff speeds. Nevertheless, these equations are quite generally used in practice, with modifications to suit special cases.

182. The amount and details of superel are fixt largely by individual judgment (¶¶ 183 to 187), based upon local conditions, by the nature of the traffic, etc. On the score of safety and for the comfort of passengers, the superel is usually adjusted for the *higher* speeds expected; but this may entail heavy work upon long and slow trains; and, where a train stops upon a sharp curv, a high superel causes an objectionable cant in the car bodies.

183. The superel is customarily taken at from 0.5 to 1.0 inch (in some cases, 1.25, 1.5 or even 2 ins) **per degree of sharpness;** with a max total limit of from 4 to 6 (or even 8) inches; speed being reduced where necessary Eq (114) requires a superel of 0.5 inch per deg of sharpness at about 27 miles/hr, 1 inch at about 38 m/h, and 2 ins at about 55 m/h.

198. In the *ideal* transition curv, the radius diminishes proportionally as the dist from the beginning of the spiral, (*measured along the spiral itself*) increases. On such a curv, the superel, at each point, is that proper to the sharpness at that point, at the contemplated velocity. This curv was described by Mr. Ellis Holbrook, in Railroad Gazette, 1880 Dec 3, p 639. It was treated by Prof. A. N. Talbot, in Technograph (University of Illinois) No. 5, 1890-91, and afterward elaborated by him in "The Railway Transition Spiral", New York, Eng News Pub Co, 1904. In "The Transition Curve", New York, John Wiley & Sons, 1899, Prof. C. L. Crandall develops accurate methods for the application of this curv to cases of large sweep. This spiral was recommended for use by the Committee on Track of the Am Ry Eng & M W Assn, Bulletin 73, March 1906, pp 58 etc.

199. Many forms of transition curv have been proposed and elaborated. Between those in common use, the choice is governd rather by facility of computation and of location than by any mechanical differences between the behaviors of the several curvs in operation.

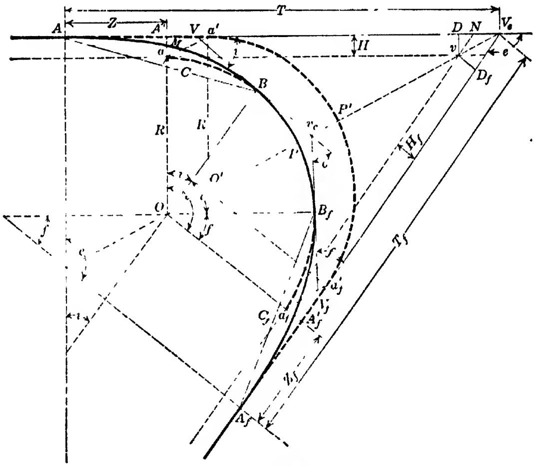


Fig. 81a.

The 10-chord Spiral

200. In the interest of simplification of the necessary formulas, the **American Railway Engineering Association** ("Manual", 1915, page 132) recommends the use of a curv, practically identical with the ideal spiral just described. Said recommended curv is subtended by ten equal spiral chains (usually much shorter than 100 ft), and is called "the ten-chord spiral". In this curv, the sharpness increases with the dist from the beginning of the spiral, measured in 100-ft chains, instead of along the curv itself, as in the true spiral. See example, ¶ 233.

Geometrical Properties. See rules for field use, ¶¶ 231 etc.

Symbols.

201. Figs 81*a*, 81*b*. Let the points, A, B, B_f, A_f, etc, of change be designated as follows (A R E A "Manual", 1915, p 135).

(A)	T. S.	From	tangent to spiral (hitherto called P. S., Point of Spiral) ;
(B)	S. C.	From	spiral to circular curv ;
(B_f)	C. S.	"	circular curv to spiral ;
(A_f)	S. T.	"	spiral to tangent ;
	S. S.	"	spiral to spiral (from one spiral to another).

202. Alfabetical list of symbols. In general, the functions of the *final* spiral are distinguisht by the subscript, $_f$.

Figs	Symbols	Meanings
81, 82	C	= the chord, $A\ B$, in ft, from T. S. to S. C. ;
	C_n	= " " , in ft, from T. S. to any given point, P, on the spiral ;
	c	= the spiral chain used, in ft ;
	c	= Δ_c. See Δ_c below.
81	D	= the sharpness of the central circular curv, $B\ B_f$
		= (practically) the sharpness of either spiral at the point, B or B_f, where it joins the circular curv ;
	d	= the sharpness of the spiral at any given point ;
81*a*	E	= the external distance $P\ V_e$ of the entire curv, $A\ B\ B_f\ A_f$, when the two spirals are equal. So defined by Am Ry Eng Assn. Compare ¶¶ 238, 239.
	e	= Δ_e. See Δ_e below.
82, 83	F	= the angle between the initial tangent, $A\ V$, and the chord, $P'\ P'''$, joining any two given spiral points ;
83	f	= the angle, $m\ P'\ P'''$, at any given spiral point, P', betw the tan, $P'\ m$, at that point, and the chord, $P'\ P'''$, to another given spiral point, P'' ;
	f	= Δ_f. See Δ_f below.
81, 82, 84, 86..	H	= the dist, $A'\ a$, betw the tan, $A\ V$ or $A'\ V_e$, and the parallel tan, $a\ v$, to the circular curv, $a\ B$ ($B\ B_f$, produced) ;
		= the ordinate of the point, a, of the circular curv produced, referd to the T S. (Abscissa = Z) ;
	i	= Δ_i. See Δ_i below.
	k	= the increase in spiral sharpness per 100-ft chord ;
	L	= the sum, in ft, of the lengths of the 10 equal spiral chains ;
	l	= the sum, in ft, of the lengths of the spiral chains betw the T. S., at A, and any given point on the spiral ;
	n	= the number (1, 2, 3....10) denoting any one of the 10 chain pts on the spiral, counting from the T. S. as zero ;
		= the number of spiral chains betw the T. S. and any given point on the spiral ;
	q	= the number of 100-ft chains betw any two given spiral points, P' and P'' ;
81, 82, 84, 86..	R	= the radius of the central circular curv ;
	S	= the number of 100-ft chains from T. S. to S. C. ;
	s	= the number of 100-ft chains betw the T. S. and any given spiral point ;

81, 82 ... T_a, T_b = the initial and final semitans, *A V* and *V B*, of the spiral;

t_a, t_b = the initial and final semitans for any portion of the spiral;

81, 84 .... T, T_f = the initial and final semitangents, $A V_e$, $V_e A_f$, of the entire curv;

82 .... X, Y = the abscissa and ordinate of the S. C. (*B*), referd to the T. S. (*A*);

x, y = the abscissa and ordinate of any given spiral point, referd to the T. S. (*A*);

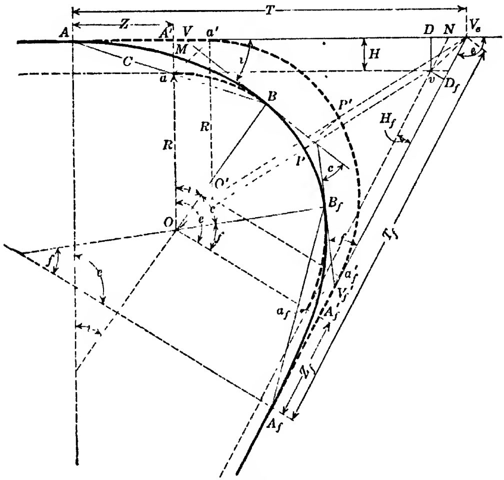

Fig. 81b.

81, 82 .... Z = $A A'$ = abscissa of the point *a*, of the circular curv produced, referred to the T. S.; (ordinate = *H*);

81, 82 .... Δ or Δ_i or *i*. See Δ_i below.

81, 86 .. Δ_c or *c* = sweep of central circular curv, $B B_f$*;

81, 84, 86. Δ_e or *e* = " " entire curv, $A B B_f A_f$;

81 ...... Δ_f or *f* = " " final spiral, $B_f A_f$*;

81, 82 ... Δ_i or *i* = " " initial spiral, $A B$*;

83 .... δ = the sweep of any given portion of the spiral, beginning at the T. S., (*A*);

= the angle betw the initial tan, *A V*, and the tan thru any given spiral pt;

See also next page.

---

*Where only the initial (or the final) spiral is under discussion, it is usually convenient to designate the sweep as Δ; but where the initial and final spirals are discust together, it may be necessary to distinguish betw their respectiv sweeps, and the subscripts are then used, with or without the letter, Δ.

81, 82 .... Θ = the peripheral or "deflection" angle, $V A B$, at the T. S. (A), betw the initial tan, $A V$, and the chord, $A B$, of the spiral;

θ = the peripheral or "deflection" angle betw the tan, $A V$, at A, and the chord from A to any given spiral point;

81, 82 .... Φ = the peripheral or "deflection" angle, $V B A$, at the S. C. (B), betw the final tangent, $V B$, thru the S. C., and the chord, $A B$;

ϕ = the peripheral or "deflection" angle, at any given spiral point, betw the tangent thru that point and the chord from the T. S.

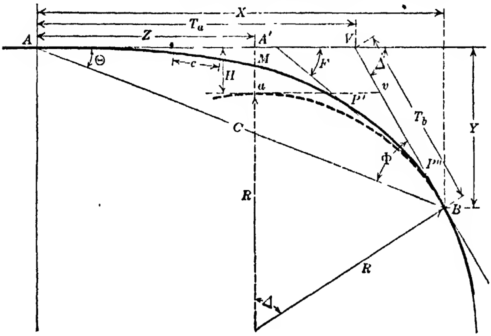

Fig. 82.

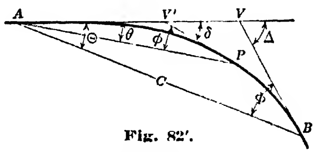

Fig. 82'.

Equations.

203. Figs 82, 82'. **Relations between L, l, S, s, c, n and q.**

$L = 100\,S = 10\,c;\quad S = 0.01\,L;\quad c = 0.1\,L = 10\,S;$

$l = 100\,s = nc;\quad n = l/c = 100\,s/c;$

$q = s'' - s' = 0.01\,c\,(n'' - n')$

$s = 0.01\,l = d/k = 0.01\,c\,n = 0.001\,n\,L$ .... (121)

204. Sharpness. D or d.

$D = k\,S = 0.01\,k\,L = 2\,\Delta/S = 200\,\Delta/L$ .... (122)

$d = k\,s = 0.01\,k\,l = 2\,\delta/s = 200\,\delta/l = n\,\Delta/5\,S$

$= 0.01\,k\,c\,n$ .... (123)

205. Rate, k, of change of sharpness.

$k = D/S = 100\,D/L = d/s = 100\,d/l = 2\,\Delta/S^2$

$=$ (approx) $6\,\Theta/S^2 = 2\,\delta/s^2 =$ (approx) $6\,\theta/s^2$ .... (124)

See also eq (133)

206. Sweep. Δ **or** δ.

$\Delta_s = \Delta + \Delta_c + \Delta_f$ .... (125)

$\Delta = D\,S/2 = D\,L/200 = k\,S^2/2 = k\,L^2/20{,}000$

$= (10/n)^2\,\delta = (S/s)^2\,\delta = (L/l)^2\,\delta$

$= \text{(approx)}\,1.854\,\sqrt{D\,H}$ .... (126)

$\delta = d\,s/2 = d\,l/200 = d^2/2\,k = k\,s^2/2 = k\,l^2/20{,}000$

$= (n/10)^2\Delta = (s/S)^2\Delta = (l/L)^2\Delta$ .... (127)

Peripheral or deflection angle, Θ **or** θ.

The angle between a tangent and a chord.

For equations for field use, see ¶ 231.

Value of deflection angle, θ, **at T. S., or beginning (A) of spiral,** betw the tan, $A\,V$, and the chord joining A with any given spiral point, P, Fig 82'

207. Let δ = the sweep of the spiral between A and the given point, P, Fig 82'. Then,

θ approx* $= \delta/3$ .... (128)

For the true value of θ, we have, very closely,

$\delta/3 - \theta$, in seconds, $= 0.00297\ (\delta \text{ in degrees})^3$.

Thus, let $\delta = 30°$; θ approx $= 30°/3 = 10°$. Then:—

$\delta/3 - \theta$, in seconds, $= 0.00297 \times 30^3$
$= 0.00297 \times 27{,}000$
$= 80.19$ seconds

or, $\theta = (\delta/3) - 0.00297\,(\delta°)^3 = 10° - 80.19$ seconds
$= 36{,}000'' - 80.19'' = 35{,}919.81'' = 9°58'39.81''$.

Taking θ approx $= \delta/3$, we have:—

θ_{approx}, in degrees $= \delta°/3 = k°s^2/6 = d°s/6$ ..... (129)

θ_{approx}, in minutes $= 10\,k°\,s^2 = 10\,d°\,s$ .... (130)

Hence, Figs 81, 82, for the angle $\Theta = V\,A\,B$, betw the tan, $A\,V$, and the chord, $A\,B$, from A to the end, B, of the spiral, we have:—

Θ approx, in minutes, $= 10\,k°\,S^2 = 10\,D°\,S$ ..... (131)

Value of deflection angle, θ_1, at the T. S. (A), betw the tan, $A\,V$, and the chord joining A with **the first spiral point,** $n = 1$.

208. Let s_1, $(= 0.01\,c)$, θ_1 and δ_1 be the values of s, of θ and of δ, respectivly, for point $n = 1$, at the end of the first of the ten spiral chains.

If Δ is less than 45° (as it always is, in practice), we have, from eq (127), for the sweep, δ_1, subtended by the first spiral chain: $\delta_1 < 0.45°$; and, from eq (128) practically:—

$\theta_1 = \delta_1/3 = d_1\,s_1/6 = s_1^2\,k/6 = (0.01\,c)^2\,k/6$ .. (132)

whence

$k = 6\,\theta_1/s_1^2 = 6\,\theta_1/(0.01\,c)^2$ .... (133)

From eq (127), we have:—

$\delta_1 = (1/10)^2\,\Delta = \Delta/100$ .... (134)

and

$\theta_1 = \delta_1/3 = \Delta/300$ .... (135)

From eq (130), we have:—

θ_1, in minutes, $= 10\,k°\,(S/10)^2 = k°\,S^2/10$
$= D°\,S/10 = D°\,s_1$ .... (136)

Values of the deflection angles, F and f, betw a tan and the chord, P' P'', joining any two spiral points. Figs 83a and 83b.

Let

F = the angle betw the initial tan, $A\,V$, and the chord, $P'\,P''$;
f = the angle, at P'', betw the tan, $P''\,m$, and the chord $P'\,P''$.

---

*Degree of approximation. Error = $0.00297\ (\delta°)^3$.

When δ =	10°	20°	30°	40°	50°
Error =	2.97	23.8	80.2	190	371 secs
1000 × error/δ =	0.08	0.33	0.74	1.32	2.06

209. Let

d', d'' = the sharpnesses at P' and at P'', respectivly;

δ' = the sweep betw A and P'
= the angle, at V', betw the initial tan, $A\ V$, thru A, and the tan, $V'\ m$, thru P';

s', s'' = the number of 100-ft chains betw A and P', and betw A and P'', respectivly;

q = $s'' - s'$ = the number of 100-ft chains betw P' and P''.

Required, F and f; ($f = F - \delta'$.)

210. Fig 83*a*.* From any spiral point, P', let a *circular* curv, $P'\ c$, be run, with the sharpness, d' of the spiral at P'. This *circular* curv diverges from the tan, $P'\ m$, at P', at the *constant* rate of d' degrees per 100-ft chord; but the *spiral*, $P'\ P''$, diverges from the same tan, $P'\ m$, at the constantly *increasing* rate of $(d' + k)°$ per 100-ft chord, where k = the increase in spiral sharpness per 100-ft chord.* Hence, the *spiral*, $P'\ P''$, diverges from the *circular* curv, $P'\ c$, at the constantly increasing* rate of $k°$ per 100-ft chord; but this k is also the rate at which the spiral, $A\ P''$, diverges from the initial tan, $A\ V$, at A. Or (since any point in the spiral may be taken as P') let P' be taken at A.* Then, at A, the initial tan, $A\ V$, the tan thru P' (now taken at A), and the circular curv (here a straight line; sharpness, d', = 0°) coincide; and we have (with P' at A): $d' = 0$; and

spiral divergence rate from the tangent thru A
= spiral divergence rate from the tangent thru P' (taken at A)
= spiral divergence rate from the circular curv beginning at P' (taken at A) = $(d' + k)°$ = $k°$.

211. In q 100-ft chords from P', the circular curv, $P'\ c$, describes a sweep of $q\ d'$ degrees, and a peripheral or "deflection" angle = half $q\ d'$; or

$$m\ P'\ c \quad = \quad q\ d'/2 \ \dots\dots\dots\dots\dots\dots (137)$$

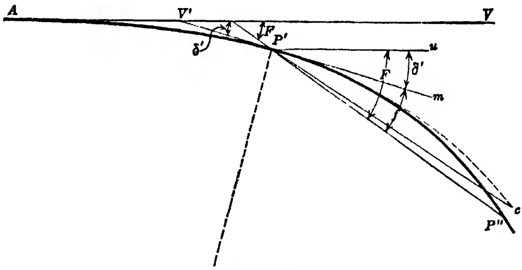

Fig. 83a.

212. In the same distance, q, the spiral increases its sharpness, over that of the circular curv, $P'\ c$, by $q\ k°$; its *mean* sharpness-increase is $q\ k°/2$; and its sweep-increase, over that of the circular

*In Fig 83*b*, the spiral sharpness increase rate, k, is *negativ*; *i. e.*, the sharpness *decreases* from P' toward P'', and the spiral diverges from the circular curv at a *decreasing* rate of $(d' - k)°$ per 100-ft chord. Also, in Fig 83*b*, if P' be taken at A, then P'' also is at A.

curv, is $q\,(q\,k°/2) = q^2\,k°/2$; but the divergence, $c\,P'\,P''$, of the spiral *chord*, $P'\,P''$, from the circular curv chord, $P'\,c$, is only one-third of $q^2\,k°/2$ (see eq 128); or

$$c\,P'\,P'' = q^2\,k/6 \quad \dots\dots\dots\dots (138)$$

213. Now

$$\begin{aligned} f = F - \delta' = m\,P'\,P'' &= m\,P'\,o + c\,P'\,P'' \\ &= \underset{\text{Eq (137)}}{q\,d'/2} + \underset{\text{Eq (138)}}{q^2\,k/6} \end{aligned}$$

$$= \frac{q}{6}\,(2\,d' + d' + q\,k) \quad \dots\dots\dots\dots (139)$$

$$= \frac{q}{6}\,(2\,d' + d'') \quad \dots\dots\dots\dots (140)$$

and

$$F = \delta' + q\,d'/2 + q^2\,k/6 = \delta' + \frac{q}{6}\,(2\,d' + d'') \quad \dots (141)$$

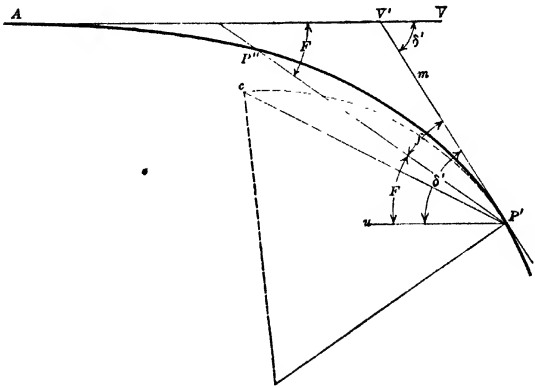

FIG. 240.

Value of f in terms of θ_1.

214. Let $m = f/\theta_1$. From eq (140) and eq (132) we have :—

$$\left.\begin{aligned} m &= \frac{f}{\theta_1} = q\,\frac{2\,d' + d''}{d_1\,s_1}; \\ \text{or } f &= m\,\theta_1 = \theta_1\,q\,\frac{2\,d' + d''}{d_1\,s_1} \end{aligned}\right\} \quad \dots\dots (142)$$

215. Thus, let $c = 20$ ft; $k = 2°$.

Then, $s_1 = 0.01\,c = 0.2$, and $d_1 = s_1\,k = 0.4°$; $d_1\,s_1 = s_1^2\,k = 0.08$; $\theta_1 = d_1\,s_1/6 = 0.0133\ldots$; and, for instance:

Sighting		$q =$	$d' =$	$d'' =$	$m = f/\theta_1 =$	$f =$
from sta	to sta	$0.01\,c \times (n'' - n')$	$0.01\,k\,c\,n'$	$0.01\,k\,c\,n''$	$q\,\dfrac{2\,d' + d''}{d_1\,s_1}$	$m\,\theta_1$
5	8	0.6	2.0	3.2	54	0 72
8	5	− 0.6	3.2	2.0	− 63	− 0.84

For θ_1, see eq (132).

216. For values of the coeff, $m = f/\theta_1$, to be used in obtaining the deflection angle, f, for locating any spiral point, P'', from any inst point, P', see Table, ¶ 233.

Values of the deflection angles F_a and f_a betw a tan and the chord $P'\,P''$ ($= 1$ spiral chain) joining two *adjacent* spiral chain points.

217. Figs 83. Let the points, P' and P'', be now two *adjacent* spiral chain points, n and $n + 1$. Then, from eqs (140) and (123), we have (since now $q = S/10$):—

$$f_a = \frac{S}{60} \times \frac{2\,n + n + 1}{5\,S}\,\Delta = \frac{3\,n + 1}{300}\,\Delta \quad \ldots\ldots (143)$$

and, from eq (127), we have:—

$$\delta' = \frac{n^2}{100}\,\Delta = \frac{3\,n^2}{300}\,\Delta \quad \ldots\ldots\ldots\ldots (144)$$

Hence:—

$$F_a \;(= f_a + \delta') = \frac{3\,n^2 + 3\,n + 1}{300}\,\Delta\,; \quad \ldots\ldots\ldots (145)$$

Let $m_a = 3\,n^2 + 3\,n + 1 = 300\,F_a/\Delta$. Then for the nine points, from $n = 0$ to $n = 9$, sighting from n to $n + 1$, or vice versa, we have, respectivly:—

$n =$	0	1	2	3	4
$n + 1 =$	1	2	3	4	5
$m_a = \dfrac{300}{\Delta}\,F_a =$	1	7	19	37	61
$m_a/300 = F_a/\Delta =$	0 0033	0.0233	0.0633	0.1233	0.2033
$n =$	5	6	7	8	9
$n + 1 =$	6	7	8	9	10
$m_a = \dfrac{300}{\Delta}\,F_a =$	91	127	169	217	271 . . . (146)
$m_a/300 = F_a/\Delta =$	0.3033	0.4233	0.5633	0.7233	0.9033

from which, and from $F_a = \dfrac{m_a}{300}\,\Delta$, the several values of F_a, for the 10 chain points, are easily found, for any given value of Δ.

218. Thus, at station $n = 7$, sighting to station $n + 1 = 8$, the angle, F_a, betw the sight, 7-8, and the initial tan, $A\,V$, is

$$F_a = \frac{m_a}{300}\,\Delta = \frac{169}{300}\,\Delta = (0.5633\ldots)\,\Delta\,.$$

219. Figs 81, 82. **Value of deflection angle, Θ**, at A, betw the tan $A\ V$ and the chord $A\ B$. Let the successiv values of F_a, thus found, be

$$F_1 = \frac{\Delta}{300}\ ; \quad F_2 = 7\ \frac{\Delta}{300}\ ; \quad F_3 = 19\ \frac{\Delta}{300};\ \text{etc};$$

and let x_1, x_2, x_3, etc, y_1, y_2, y_3, etc, be the co-ordinates for the points, $n = 1$, $n = 2$, $n = 3$, ... $n = 10$ (point B). Let $L =$ the sum of the spiral chains, in ft; $c = L/10$.

Then

$$x_1 = c \cos F_1\ ; \qquad y_1 = c \sin F_1$$
$$x_2 = c\ (\cos F_1 + \cos F_2)\ ; \qquad y_2 = c\ (\sin F_1 + \sin F_2) \quad ..(147)$$
$$\text{etc.} \qquad\qquad \text{etc.}$$

$$\text{Tan}\ \Theta = \tan V\ A\ B = \frac{Y}{X} = \frac{\sin F_1 + \sin F_2 + \ \ldots \sin F_{10}}{\cos F_1 + \cos F_2 + \ \ldots \cos F_{10}} \quad ..(148)$$

From values of functions of Θ, thus found, the value is derived:

$$\left(\frac{\Delta}{3} - \Theta\right) \text{in seconds} = 0.002\,97\ \ (\Delta \text{ in degrees})^3$$

or, $$\Theta = \Delta/3 - [0.002\,97\ (\Delta^\circ)^3]\ \text{seconds} \quad .....(149)$$

Value of the deflection angle, Φ, at the S.C. (B), betw the tan $V\ B$ and the chord $A\ B$.

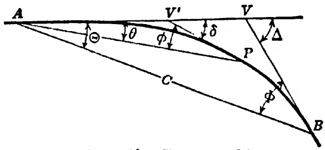

Fig. 82'. (Repeated.)

220. Figs 81, 82. Necessarily, $\Delta = \Theta + \Phi$; or

$$\Phi = \Delta - \Theta = \Delta - \left[\frac{\Delta}{3} - (0.002\,97\ (\Delta \text{ in degrees})^3 \text{ seconds*})\right].$$

Hence:—

$$\Phi = \frac{2}{3}\Delta + \left(0.002\,97\ (\Delta \text{ in degrees})^3 \text{ seconds*}\right) \quad ....(150)$$

Practically*:— $\Phi = 2\,\Delta/3 = 2\ \Theta$ ....(151)

Similarly, Fig 82', in any portion, $A\ P$, of the spiral curv, $A\ P\ B$, said portion beginning at the T.S. (A), we have, practically:—

$$\delta = \theta + \phi\ ;$$
$$\theta = \delta/3\ ;$$
$$\phi = 2\,\delta/3 = 2\,\theta \quad ....(151')$$

221. Relations between H, L and Z. Fig 82.

$$H = \text{approx}\ \frac{L^2}{24\ R} = \frac{L^2}{24} \cdot \frac{D}{5730} = 0.0727\ S^2\ D \quad ..(152)$$

$$L = \sqrt{24\ R\ H} = 4.9\sqrt{R\ H} = 4.9\sqrt{5730\ H/D}$$
$$= 371\sqrt{H/D} \quad ....(153)$$

$$\Delta = 0.005\ D\ L\ (\text{eq } 126) = 0.005\ D\ 371\sqrt{H/D}\ (\text{eq } 153)\ ;\ \text{or}$$
$$\Delta = 1.854\sqrt{D\ H} \quad ....(154)$$

---

*See *note, p 971.

215. Thus, let $c = 20$ ft; $k = 2°$.

Then, $s_1 = 0.01\,c = 0.2$, and $d_1 = s_1 k = 0.4°$; $d_1 s_1 = s_1^2 k = 0.08$; $\theta_1 = d_1 s_1/6 = 0.0133\ldots$; and, for instance:

Sighting		$q =$	$d' =$	$d'' =$	$m = f/\theta_1 =$	$f =$
from sta	to sta	$0.01\,c \times (n'' - n')$	$0.01\,k\,c\,n'$	$0.01\,k\,c\,n''$	$q\,\dfrac{2\,d' + d''}{d_1\,s_1}$	$m\,\theta_1$
5	8	0.6	2.0	3.2	54	0 72
8	5	− 0.6	3.2	2.0	− 63	− 0.84

For θ_1, see eq (132).

216. For values of the coeff, $m = f/\theta_1$, to be used in obtaining the deflection angle, f, for locating any spiral point, P'', from any inst point, P', see Table, ¶ 233.

Values of the deflection angles F_a and f_a betw a tan and the chord $P'\,P''$ ($= 1$ spiral chain) joining two *adjacent* spiral chain points.

217. Figs 83. Let the points, P' and P'', be now two *adjacent* spiral chain points, n and $n + 1$. Then, from eqs (140) and (123), we have (since now $q = S/10$) :—

$$f_a = \frac{S}{60} \times \frac{2\,n + n + 1}{5\,S}\,\Delta = \frac{3\,n + 1}{300}\,\Delta \ \ldots\ldots (143)$$

and, from eq (127), we have :—

$$\delta' = \frac{n^2}{100}\,\Delta = \frac{3\,n^2}{300}\,\Delta \ \ldots\ldots\ldots\ldots\ldots (144)$$

Hence :—

$$F_a\ (= f_a + \delta') = \frac{3\,n^2 + 3\,n + 1}{300}\,\Delta\ ;\ \ldots\ldots\ldots\ldots (145)$$

Let $m_a = 3\,n^2 + 3\,n + 1 = 300\,F_a/\Delta$. Then for the nine points, from $n = 0$ to $n = 9$, sighting from n to $n + 1$, or vice versa, we have, respectivly :—

$n =$	0	1	2	3	4
$n + 1 =$	1	2	3	4	5
$m_a = \dfrac{300}{\Delta}\,F_a =$	1	7	19	37	61
$m_a/300 = F_a/\Delta =$	0 0033	0.0233	0.0633	0.1233	0.2033
$n =$	5	6	7	8	9
$n + 1 =$	6	7	8	9	10
$m_a = \dfrac{300}{\Delta}\,F_a =$	91	127	169	217	271 . . . (146)
$m_a/300 = F_a/\Delta =$	0.3033	0.4233	0.5633	0.7233	0.9033

from which, and from $F_a = \dfrac{m_a}{300}\,\Delta$, the several values of F_a, for the 10 chain points, are easily found, for any given value of Δ.

218. Thus, at station $n = 7$, sighting to station $n + 1 = 8$, the angle, F_a, betw the sight, 7-8, and the initial tan, $A\,V$, is

$$F_a = \frac{m_a}{300}\,\Delta = \frac{169}{300}\,\Delta = (0.5633\ldots)\,\Delta .$$

Selection of spiral.

227. Fig 82. The selection of the length, L, of the spiral may be **restricted by the value of H,** as determind by topographical or other conditions. We then have (eq 153), for length of spiral:—

$$L = \sqrt{24\,R\,H};$$

where R = radius of circular curv.

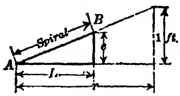

Fig. 83½.

228. Fig. 83½. Where the choice of spiral is not thus restricted, the length, L, is **determind by the superelevation, e,** in ft (or E in inches) on the circular curv, and by the rate, r, of run-off in ft of line per ft of e (¶¶ 190-193); thus (eq 117):—

$$L = e\,r = 0.3273\,V^2\,r/R = 0.1522\,v^2\,r/R = 0.1522\,v^3\,t/R \ldots\ldots (174)$$

where $t = r/v$ = time, in seconds, during which the outer wheel, on the runoff, would rise 1 foot.

The Am Ry Eng Assn rule, eqs (175), gives $t \not< 5.45$ when V = 45 miles/hr, and superel = 8 ins = 2/3 ft.

229. The Am Ry Eng Assn (Manual, 1915, pp 131-132) recommends —

On curvs which do not limit the speeds of trains:—

$$L \not< 360\,e_u; \quad \text{or} \quad L \not< 8\,V_u\,e_u \ldots\ldots\ldots\ldots (175)$$

On curvs which limit the speeds of trains:—

When $D < 6°$, $L \not< 16\,V_8 / 3$; when $D \not< 6°$, $L \not< 240 \ldots (176)$

where

L = spiral length, in ft;
V_u = ultimate speed, in miles/hr; e_u = superel, in ft, for V_u;
V_8 = speed in miles/hr calculated for an elevation of 8 ins.

$$= \sqrt{\frac{8\,R}{3.928}} \quad \text{(see eq 118).}$$

With V = 45 miles/hr, and superel, E, = 8 ins, or e = 2/3 ft, each of these rules gives $L \not< 240$ feet.

230. In practice, and in order to avoid the use of sub-chains in the spiral, a length deviating somewhat from the calculated length, L, of spiral, may be used.

For instance, with H = 9.6 ft, circular curv 5° (R = 1146.3 ft), we have (eq 153):— $L = \sqrt{24\,R\,H}$ = 513.9 ft.

With V = 50 m/h, on a 6° curv (R = 955.4 ft), rate, r, of run-off = 600, we have (eq 174):—

$$L = r\,0.3273\,V^2/R = 513.9 \text{ ft.}$$

In either case, we may use 500 ft (10 chains of 50 ft) or 510 ft (10 chains of 51 ft) or 525 ft (10 chains of 52.5 ft), etc.

Location.

Condensed results, for field use.

By deflection angles.

231. The spiral may be conveniently located by turning off "deflection" angles from a tan, as in locating a circular curv; but, in thus locating a spiral, the successiv increments, in the total deflection angle turnd off from the tan at a given inst point, increase regularly, instead of being constant as in the case of a circular curv.

215. Thus, let $c = 20$ ft; $k = 2°$.

Then, $s_1 = 0.01\,c = 0.2$, and $d_1 = s_1 k = 0.4°$; $d_1 s_1 = s_1^2 k = 0.08$; $\theta_1 = d_1 s_1/6 = 0.0133\ldots$; and, for instance:

Sighting		$q =$	$d' =$	$d'' =$	$m = f/\theta_1 =$	$f =$
from sta	to sta	$0.01\,c \times (n'' - n')$	$0.01\,k\,c\,n'$	$0.01\,k\,c\,n''$	$q\,\dfrac{2\,d' + d''}{d_1\,s_1}$	$m\,\theta_1$
5	8	0.6	2.0	3.2	54	0 72
8	5	− 0.6	3.2	2.0	− 63	− 0.84

For θ_1, see eq (132).

216. For values of the coeff, $m = f/\theta_1$, to be used in obtaining the deflection angle, f, for locating any spiral point, P'', from any inst point, P', see Table, ¶ 233.

Values of the deflection angles F_a and f_a betw a tan and the chord $P'\,P''$ ($= 1$ spiral chain) joining two *adjacent* spiral chain points.

217. Figs 83. Let the points, P' and P'', be now two *adjacent* spiral chain points, n and $n + 1$. Then, from eqs (140) and (123), we have (since now $q = S/10$):—

$$f_a = \frac{S}{60} \times \frac{2\,n + n + 1}{5\,S}\,\Delta = \frac{3\,n + 1}{300}\,\Delta \ \ldots\ldots (143)$$

and, from eq (127), we have:—

$$\delta' = \frac{n^2}{100}\,\Delta = \frac{3\,n^2}{300}\,\Delta \ \ldots\ldots\ldots\ldots\ldots (144)$$

Hence:—

$$F_a\ (= f_a + \delta') = \frac{3\,n^2 + 3\,n + 1}{300}\,\Delta\ ;\ \ldots\ldots\ldots\ldots (145)$$

Let $m_a = 3\,n^2 + 3\,n + 1 = 300\,F_a/\Delta$. Then for the nine points, from $n = 0$ to $n = 9$, sighting from n to $n + 1$, or vice versa, we have, respectivly:—

$n =$	0	1	2	3	4
$n + 1 =$	1	2	3	4	5
$m_a = \dfrac{300}{\Delta}\,F_a =$	1	7	19	37	61
$m_a/300 = F_a/\Delta =$	0 0033	0.0233	0.0633	0.1233	0.2033
$n =$	5	6	7	8	9
$n + 1 =$	6	7	8	9	10
$m_a = \dfrac{300}{\Delta}\,F_a =$	91	127	169	217	271 . . . (146)
$m_a/300 = F_a/\Delta =$	0.3033	0.4233	0.5633	0.7233	0.9033

from which, and from $F_a = \dfrac{m_a}{300}\,\Delta$, the several values of F_a, for the 10 chain points, are easily found, for any given value of Δ.

218. Thus, at station $n = 7$, sighting to station $n + 1 = 8$, the angle, F_a, betw the sight, 7-8, and the initial tan, $A\,V$, is

$$F_a = \frac{m_a}{300}\,\Delta = \frac{169}{300}\,\Delta = (0.5633\ldots)\,\Delta.$$

Example. Given

c = spiral chain length, = 20 ft;

k = increase of spiral sharpness, d, per 100-ft chord, = 3°.

Then :—

Eq (121) Length, L, of spiral, $A B$, in ft, measured along spiral chains, = 10 c = 10 × 20 = 200 ft;

Number, S, of 100-ft chords in L, = approx 0.01 L = 2;

Eq (122) Sharpness, D, of spiral at the S.C. (B), = approx $k S$ = 3° × 2 = 6°;

Eq (126) Sweep, Δ, of spiral, $A B$, = approx $DS/2$ = 6° × 1 = 6°;

Eq (129) Defl angle, Θ = $V A B$, = app $\Delta/3$ = app 2°;

Defl angle, Φ = $V B A$, = app $2\Delta/3$ = app 4°.

Required the deflection angle, f, from the tangent, $P' m$, at the point P'' to another spiral point, P'''.

Here, eq (132)

θ_1 = $(0.01\, c)^2\, k/6$ = $0.04 \times 3°/6$ = 0.02°;

and (from table above), Fig 83a, sighting from

P'', (n = 5) to P''', (n = 8), m = 54.

Hence, in this case,

f ($= m\,\theta_1$) = 54 × 0.02° = 1.08°.

Again, Fig 83b, sighting from P', (n = 8) to P'', (n = 5), we have

f ($= m\,\theta_1$) = 63 × 0.02° = 1.26°.

234. Values of m etc, in special cases. Figs 82, 83.

(a) When the inst point, P', is at the T.S. (A) or point n = 0 (Top line of table ¶ 233).

Figs 82, 83a. When sighting (forward) from A to any other spiral point, P''', of number n, eq (142) becomes

$$m = q\,\frac{2\,d' + d''}{d_1\, s_1} = 0.01\, c\, n\,\frac{k\, s''}{0.01\, k\, c\,.\,0.01\, c} = n\,\frac{s''}{0.01\, c} = n^2;$$

and θ'' (θ for point P'') $= m\,\theta_1 = n^2\theta_1$.

Hence, when P'' is at the S.C. (B, or n = 10), we have m ($= n^2$) = 100, and Θ ($= V A B$) = 100 θ_1 = approx $\Delta/3$.*

(b) Fig 83b. When the point, P'', sighted (backward), is at the T.S. (A) or point n = 0 (Column headed T.S.).

When sighting from any other point, P', of number n, to A, we have, approx, eq (151′), $\phi = 2\,\theta$.

Hence, when the inst point, P', is at the S.C. (B, or n = 10), we have Φ ($= V B A$) = 200 θ_1 = approx $2\,\Theta = \dfrac{2}{3}\Delta$.*

By offsets from the initial tangent, A V.

235. Fig 82. The offsets, x and y (eqs 147, 158, 159) to each of the points in the entire spiral $A B$, may be measured from the initial tan, $A V$.

Or, make the offset, $A' M$, for the middle point, M, of the spiral, = $A' a/2$ = $H/2$ (¶222), and the remaining offsets proportional to the cubes of their dists from A and from B respectivly, measuring the offsets for the first half of the spiral inward at right angles from the tan $A V$, and the remainder radially outward from the circular curv, $a B$.

By offsets from long chord, A B. (E. S. M. Lovelace, Canadian Soc Civ Engrs. Reprinted in Engng & Contractg, 1914 Mar 25).

236. Fig 82. Let

h = the normal offset from the long chord to any given point in the spiral;

H = dist betw parallel tans, $A V$ and $a v$;

n = number of spiral chains betw the T. S. (A) and the given point;

N = number of spiral chains in the spiral.

---

*See foot-note *, p 971.

Then, **in any spiral:**

$$\frac{h}{H} = 4\,n\,\frac{N^2 - n^2}{N^3} \quad \ldots\ldots\ldots\ldots\ldots\ldots (177)$$

This equation, derived for the lemniscate, is closely approx for the A R E A 10-chord spiral,

In the 10-chord spiral, $N = 10$; so that

$$\frac{h}{H} = 4\,n\,\frac{100 - n^2}{1000} = 0.4\,n - 0.004\,n^3 \quad \ldots\ldots\ldots (178)$$

Hence we have:

When

$n =$	0	1	2	3	4	5	6	7	8	9	10
$h/H =$	0	0.396	0.768	1 092	1.344	1.500	1.536	1 428	1.152	0.684	0

h is a max ($= 1.54\,H$) when $n = N/\sqrt{3} = 10/1.7321 = 5.77$.

237. (a) Figs 81, 84, 85. Original circular curv, $a'\,a_f'$, shifted **without change of radius,** thru a given dist, $a'\,a$, (equal and parallel to $V_e\,v$ and to $a_f'\,a_f$) to a new position, $a\,a_f$.

Required the semitangents, T and T_f, to the entire curv, ABB_fA_f, **Fig 81.**

(1) Figs 81*a*, 84. The two spirals similar. Shift, $a'\,a$, parallel to common bisector $O\,v$, of $a'\,a_f'$ and of $a\,a_f$; $T_f = T$; $H_f = H$. R = rad of circular curv.

Here $H = H_f = a'\,a\,\cos(\Delta_e/2)$ ……………………… (179)

$T = T_f = (R + H)\tan(\Delta_e/2) + Z$ …………… (180)

From eqs (153 and 157), we have

$$Z = \frac{L}{2} - \frac{L^3}{1280\,R^2} = \text{practically } \frac{\sqrt{24\,R\,H}}{2} = 2.45\,\sqrt{R\,H}.$$

(2) Figs 81*b*, 85, The two spirals dissimilar. Shift, $a'\,a$ (equal and parallel to $V_e\,v$ and to $a_f'\,a_f$), not parallel with bisector, $O\,v$ or $O'\,V_e$.

T_f and T unequal. H_f and H unequal.

For T and T_f, see eq (172).

For H and H_f, see eq (169).

238. (b) Fig 86. Retaining the original middle point, P', and shortening the radius from R' to R. The line is changed from $A\,a'\,P'$ to $A\,B\,P'$. Having determind (¶¶ 227 &c) the length, L,

and $A'\,a = H = \dfrac{L^2}{24\,R}$;

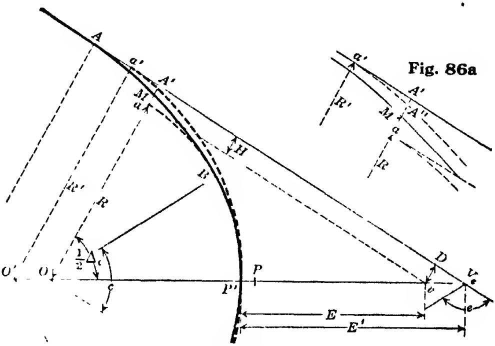

Fig. 86.

let

Δ_e = entire sweep, = 2 arc $a\,P'$ = 2 angle $a\,O\,P'$;
$A''\,M$ (Fig 86a) = max shift of center line of track;
$a'\,A'$ = shift of point a' of circular curv, toward intersection, V_e; and

Radius,	Semitan,	Ext dist,	Sharpness,	
$R' = O'\,a'$	$a'\,V_e$	$E' = P'\,V_e$	D'	of existing circular curv, $a'\,P'$;
$R = O\,a$	$a\,v$	$E = P'\,v$	D	of sharpend circular curv, $a\,P'$.

Then :

$$E = E' - V_e\,v = E' - H\ \sec(\Delta_e/2)\ ; \qquad (181)$$

$$R = \frac{E}{\text{ex sec}\ (\tfrac{1}{2}\,\Delta_e)}\ ; \qquad (182)$$

$$D = \frac{E\ \text{of}\ 1°\ \text{curv, of given sweep,}\ \Delta_e}{E} \qquad (183)$$

$$a'\,A' = (R' - R - H)\ \tan(\Delta_e/2)$$
$$= a'\,V_e - (R + H)\ \tan(\Delta_e/2) \qquad (184)$$

Practically (Fig 86a), $A''\,M = \dfrac{H}{2} - \dfrac{7}{8}\left(\dfrac{a'\,A'}{100}\right)^2 D$ ..... (185)

239. (c) Fig 86. With minimum shift of line. Shift the middle point, P' to P, making $P'\,P = H/2$. Then :

$$E = E' - H\ \sec(\Delta_e/2) - H/2 \qquad (186)$$

Use this new value of E in Eqs (182) and (183).

Then, **in any spiral:**

$$\frac{h}{H} = 4\,n\,\frac{N^2 - n^2}{N^3} \quad \ldots\ldots\ldots\ldots\ldots\, (177)$$

This equation, derived for the lemniscate, is closely approx for the A R E A 10-chord spiral,

In the 10-chord spiral, $N = 10$; so that

$$\frac{h}{H} = 4\,n\,\frac{100 - n^2}{1000} = 0.4\,n - 0.004\,n^3 \quad \ldots\ldots\ldots (178)$$

Hence we have:

When

$n =$	0	1	2	3	4	5	6	7	8	9	10
$h/H =$	0	0.396	0.768	1 092	1.344	1.500	1.536	1 428	1.152	0.684	0

h is a max ($= 1.54\ H$) when $n = N/\sqrt{3} = 10/1.7321 = 5.77$.

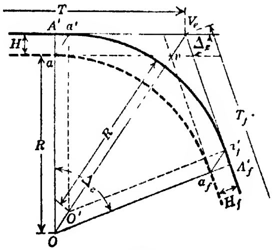

Fig. 84.

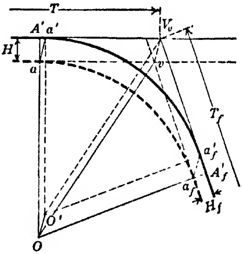

Fig. 85.

Insertion of spirals in existing track.

See also ¶ 169

237. (a) Figs 81, 84, 85. Original circular curv, $a'\ a_f'$, shifted **without change of radius,** thru a given dist, $a'\,a$, (equal and parallel to $V_e\ v$ and to $a_f'\ a_f$) to a new position, $a\ a_f$.

Required the semitangents, T and T_f, to the entire curv, ABB_fA_f, **Fig 81.**

(1) Figs 81*a*, 84. The two spirals similar. Shift, $a'\,a$, parallel to common bisector $O\ v$, of $a'\ a_f'$ and of $a\ a_f$; $T_f = T$; $H_f = H$. R = rad of circular curv.

Here $H = H_f = a'\ a\ \cos(\Delta_e/2) \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (179)$

$T = T_f = (R + H)\ \tan(\Delta_e/2) + Z \ldots\ldots\ldots\ldots (180)$

From eqs (153 and 157), we have

$$Z = \frac{L}{2} - \frac{L^3}{1280\,R^2} = \text{practically}\ \frac{\sqrt{24\,R\,H}}{2} = 2.45\,\sqrt{R\,H}.$$

(2) Figs 81*b*, 85, The two spirals dissimilar. Shift, $a'\,a$ (equal and parallel to $V_e\ v$ and to $a_f'\ a_f$), not parallel with bisector, $O\ v$ or $O'\ V_e$.

T_f and T unequal. H_f and H unequal.

For T and T_f, see eq (172).

For H and H_f, see eq (169).

much used during fogs, snow, storms, etc, when visible signals cannot well be seen. They are largely used also as an auxiliary to back-flagging, to protect the train ahed while the flagman is returning to it, or in case the following enginman fails to see him.

Fixt Signals.

7. Disc signals give their indications, by day as well as by night, solely by means of color, and not by form or position. Each disk sig is usually enclosed in a case, shaped like a banjo (whence the name, "banjo" signal) and provided with a glass face. For day use, the sig proper consists essentially of an opaque colord disc. If this disc is seen thru the glass face, it indicates "stop" when red, or "caution"* when green. To indicate "proceed", the disc is swung to one side, leaving a white background showing thru the glass face. For night use, a colord glass disc indicates "stop" or "caution" by appearing in front of a lamp; or "proceed" by being withdrawn, leaving the lamp to show thru a clear glass.

8. Semafors. Signals are usually of the semafor type, see Figs 7 to 12, incl, each consisting of a movable arm or "board", about 4′ long and 10″ wide, pivoted and mounted on a post or other suitable object.

9. Home Signal. A home sig is one at which the train must stop when the sig is set for "stop" It is placed usually at the entrance to a block, or immediately before reaching a switch, derail, crossing, drawbridge, or other object to be garded. When horizontal, such a sig indicates "stop", and by night the hor position is indicated by a red glass, which appears in front of a lantern, thus showing a red light for stop. When inclined, the sig indicates "proceed", and shows, by night, a light of some color other than red. See also "Signal aspects", ¶¶ 17, 32 and 33.

10. Distant Signal. A "Distant" or "caution"* sig, when provided, is placed at some distance (usually several thousand ft) "to the rear of" (before reaching) the "home" sig it relates to, and indicates the position of the home sig, which may be out of sight. It thus givs the enginman advance information regarding the home sig, and makes possible faster or safer running. The indications of the home and dist sigs always simultaneously correspond, unless a train is on the track between the two, in which case the dist sig shows "caution"* altho the home sig may be at "proceed".

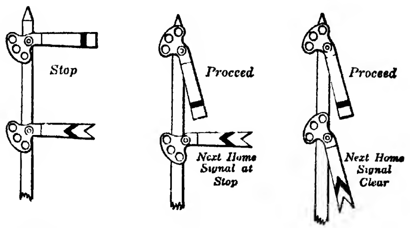

Fig. 7. Fig. 8. Fig. 9.

11. Disposition of sigs. The home sig and the dist sig for the block ahed, are usually mounted on the same post, as in Figs 7, 8 and 9; the upper one being the home, and the lower the dist sig.

---

*"Caution" is a term here used somewhat loosely, tho conveniently, to denote its usual or approx meaning: "proceed prepared to stop at next signal".

Then, **in any spiral:**

$$\frac{h}{H} = 4\,n\,\frac{N^2 - n^2}{N^3} \qquad \ldots\ldots\ldots\ldots\ldots (177)$$

This equation, derived for the lemniscate, is closely approx for the A R E A 10-chord spiral,

In the 10-chord spiral, $N = 10$; so that

$$\frac{h}{H} = 4\,n\,\frac{100 - n^2}{1000} = 0.4\,n - 0.004\,n^3 \qquad \ldots\ldots\ldots (178)$$

Hence we have:

When

$n =$	0	1	2	3	4	5	6	7	8	9	10
$h/H =$	0	0.396	0.768	1.092	1.344	1.500	1.536	1.428	1.152	0.684	0

h is a max ($= 1.54\,H$) when $n = N/\sqrt{3} = 10/1.7321 = 5.77$.

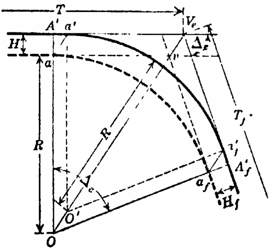

Fig. 84.

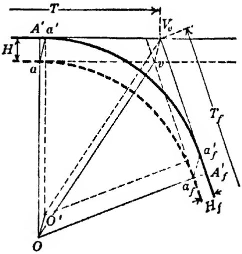

Fig. 85.

Insertion of spirals in existing track.

See also ¶ 169

237. (a) Figs 81, 84, 85. Original circular curv, $a'\,a_f'$, shifted **without change of radius,** thru a given dist, $a'\,a$, (equal and parallel to $V_e\,v$ and to $a_f'\,a_f$) to a new position, $a\,a_f$.

Required the semitangents, T and T_f, to the entire curv, ABB_fA_f, **Fig 81.**

(1) Figs 81*a*, 84. The two spirals similar. Shift, $a'\,a$, parallel to common bisector $O\,v$, of $a'\,a_f'$ and of $a\,a_f$; $T_f = T$; $H_f = H$. R = rad of circular curv.

Here $H = H_f = a'\,a\,\cos(\Delta_e/2) \ldots\ldots\ldots\ldots\ldots\ldots\ldots (179)$

$T = T_f = (R + H)\,\tan(\Delta_e/2) + Z \ldots\ldots\ldots\ldots (180)$

From eqs (153 and 157), we have

$$Z = \frac{L}{2} - \frac{L^3}{1280\,R^2} = \text{practically}\ \frac{\sqrt{24\,R\,H}}{2} = 2.45\,\sqrt{R\,H}.$$

(2) Figs 81*b*, 85. The two spirals dissimilar. Shift, $a'\,a$ (equal and parallel to $V_e\,v$ and to $a_f'\,a_f$), not parallel with bisector, $O\,v$ or $O'\,V_e$.

T_f and T unequal. H_f and H unequal.

For T and T_f, see eq (172).

For H and H_f, see eq (169).

18. Raising the arm into the upper *left*-hand quadrant, is coming largely into use on electric railroads, and has the advantage of placing the sig at the same angles as in the old familiar lower right-hand quad, and is more redily placed so as to be visible among telegraf or trolley poles.

19. Flash signals, for use at night, are being tried, especially abroad. The illuminant is usually acetylene gas, and each lamp is arranged to flash periodically (much as certain light-house lamps flash) usually burning for about 0.1 second, and being extinguisht for from about 0.3 to 0.9 second. They appear to be reliable and economical, and assist in distinguishing sig lights, in general, from other lights foreign to the railroad, and for distinguishing betw different kinds of sigs.

20. Light signals, with which no semafor is used, are economical in first cost, and have no moving parts, aside from those of the relays that control them. They are used in subways and tunnels, where a semafor could not well be seen; and to some extent on electric surface roads. Where used in daylight, each light should be accompanied by a hood or other means for preventing the direct rays of the sun from falling on the lens glass, and by a screen or shield or other large dark object, to attract attention to the sig, make it more redily visible, and so reduce the chance of its being overlookt. See also "Two-light signals", ¶ 16.

21. Light and flash signals are being experimentally combined.

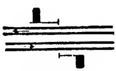

Fig. 13
Double Track

Fig. 14
Trailing Point Cross-over

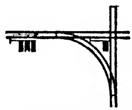

Fig. 15
Two Home and One Distant

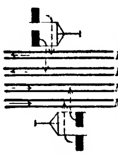

Fig. 16

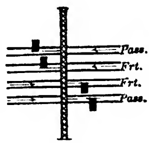

Fig. 17

Four Tracks Signaled

22. Locations of signals. Fixt visible sigs are usually placed to the right of, or directly over, the track to which they relate. Figs 13 to 17, incl, show diagrammatically certain typical sig arrangements, selected from those given in the Ry Sig Assn's "Signal Dictionary".

TRANSMISSION MECHANISM

23. Signals and switches are conveniently operated from a central point, as a sig tower; and means must be provided for connecting them with it, and for controlling them from it

Hand operated

24. Mechanical connections for hand power operation are made usually by pipes (used as rods) or by wires.

25. The pipe is usually of wrought iron or steel, one inch diam. Since it can transmit either tension or compression, only one pipe is needed (in general) for each sig or switch. The lines of pipe are usually carried upon and held in line by means of rollers held in frames. Where sharp turns must be made, the pipe ends are connected by means of bell-cranks, *B*, Fig 18 (not to scale), or by means of curvd deflecting bars, *D*, running betw rollers.

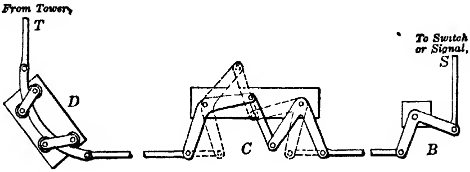

Fig. 18.

26. Compensators. Since even moderate changes in temperature materially alter the length of a pipe line, and disarrange the adjustment, the pipe lines are divided into sections, and the sects are connected by means of "compensators" or "lazy-jacks", *C*, which neutralize the effects of temp-change, without affecting the sig movements. Fig 18 represents a line of pipe, leading from the sig tower, *T*, thru a deflecting bar, *D*, a "compensator", *C*, and a bell-crank, *B*, to a switch or sig, *S*. The dotted lines show the positions of the compensator members when the pipe line is expanded by heat.

Power

27. Power operation may be effected either by comprest air, conveyd thru pipes to cylinders, in which it acts upon pistons connected with the sigs or switches; or else by electricity, conveyd by wires to electric motors (or to solenoids for small sigs). The comprest air, or electricity, which *operates* the sigs, is controld usually by means of relativly light electric circuits, or, in the all-pneumatic apparatus, by relativly low-pressure air. In either case, the power is controlled thru relays.

28. All-electric systems are coming largely into use. They have the advantage that no special air-compressing plant is needed; and various comprest air troubles are eliminated.

SYSTEMS

29. Time interval. Under this syst, a train must be given a headway of say 5, 7 or 10 mins, before a following train is permitted to proceed; the supposition being that, if the first train is unexpectedly stopt, the time interval is sufficient to permit the flagman to flag the following train; but the system, at best, is far from safe.

30. Space-interval or block. Under this syst, the length of the road is divided into sections called blocks, of suitable lengths, and where absolute blocking is practist, no two trains are permitted to be in one and the same block at the same time. The block length may vary widely from abt one mile or less to 5 or 10 miles, according to density and character of traffic.

31. Permissiv. Under permissiv blocking, a train is permitted to pass a block sig showing "stop", with the understanding that it is to run only at such diminsht speed that it can be stopt at the first point which cannot be passed with obvious and certain safety. This permits a larger train operation with a given block length; but it is less safe than absolute blocking.

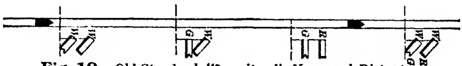

Fig. 19. *Old Standard; "2-position", Home and Distant*

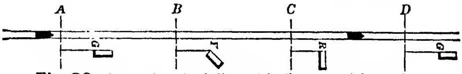

Fig. 20. *Newer Standard; "3-position", upper-right quad.*

32. Signal aspects, as frequently applied to block signaling. Figs 19 and 20 illustrate, for given conditions on a given line, the sig positions, under the **"two-position"** and **"three-position"** semafor systs, respectivly. *A B*, *B C* and *C D* represent blocks. Under either syst, the train, in block *C D*, is protected by the home sig at *C*, behind it, set at "stop"; but at the same time, a train may enter block *B C* at *B*, under the "caution" sig there; or a train may enter block *A B* at *A*, without restriction; the sig, at *A*, indicating not only "proceed", but also "next sig beyond is clear".

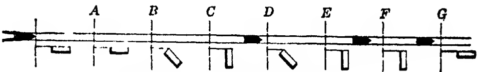

Fig. 21. *Normal "Clear"* (3-*pos.*)

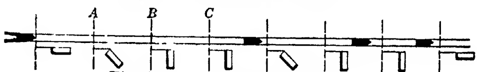

Fig. 22. *Normal "Danger"* (3-*pos.*)

33. Figs 21 and 22 illustrate, for given conditions on a given line, the semafor positions in the "three-position" syst, under the **"normal clear"** and **"normal danger"** systs, respectivly. Under the "normal clear" syst, the sig, controlling a block, always shows clear when the block is clear, whether or not a train is about to enter the block. Under the "normal danger" syst, the sig remains at danger (whether or not the block is occupied) until a train approaches the sig, to enter the block; and then, of course, the sig is cleard only if the block is actually clear. These diffs are shown in blocks *AB* and *BC*.

34. Telegraf block or manual block. Under this syst, a man is stationd at the end of each block; and, when a train passes from one block to another, the man at the passing point communicates the fact, electrically, to the men at such other points as may be necessary. The men, so advised, then display the necessary sigs.

35. The telefone is largely displacing the telegraf for such signaling, and for train dispatching generally. It is commonl, used in conjunction with selector systs, see ¶ 71.

36. Controlled Manual, or Lock and Block System. To reduce the chances of error of operation in telegraf or manual block systs, arrangements may be instald, which require the simultaneous action of both men in making or breaking electric contacts, before the sig can be set to "proceed".

37. Automatic locking. To gard against an agreement between the two men to open the block when it is not actually clear, "track instruments", or the "track circuit" (see ¶ 50) may be so arranged that this agreement cannot be made until the train has actually past out of the block.

38. Staff System. This method is especially applicable to single track roads. At each end of a block is a receptacle containing a number of metal staves or rods. The two receps are so arranged and electrically connected that only *one* staff may be taken from the receps; and this staff must be returned to one of the receps before another staff can be taken. The staff is the train's permit to travel over the block, and is carried by the train When the train leavs the block (at either end), the staff is placed in the recep at that end; rendering it again possible to remove one staff from the recep at either end of the block.

39. Special provisions may be made, to operate the machines under "permissiv blocking", and to provide for the return of "helper" engins; but this still does not permit two complete staves to be out of the receptacles at the same time.

MANIPULATION

40. Manipulation may be either *"initiativ"* or *"interlocking"*, or both. (See ¶ 3*a*.)

41. Initiativ manipulation may be either that effected by *employees*, or (either mechanical or electrical) by *the trains* themselvs

42. Interlocking manipulation (part of which may be in the "Transmission") is that of automatic devices, designed to prevent improper operations. It may be accomplisht either by purely mechanical movements, by electricity or by comprest air. Where even a few sigs and switches are operated from one point, collision of trains may be caused by errors on the part of the operators. In order to prevent this, the levers and rods are so groupt, and provided with additional sliding pieces, cald "dogs", or with electric contacts, locks, etc, that (in so far as possible) combinations or settings, which might endanger trains, are mechanically prevented.

43. Mechanical. Thus, (here considering mechanical interlocking as an illustration) at a double-track crossing, when all the sigs show "stop", any one sig may be made to show "proceed"; but, as it does so, the rod, connected with its lever, moves such dogs as will lock the levers of the sigs governing the tracks which cross its track. Thus, if the sig for a westbound train is cleard, the two sigs for northbound and for southbound movements are thereby lockt at "stop"; but the sig for the eastbound track is left clear; because both eastbound and westbound trains may of course pass over the crossing simultaneously while the northbound and southbound tracks are lockt at "stop".

44. Conversly, northbound and southbound trains can be given clear sigs only after the eastbound and westbound sigs hav been set at "stop" and lockt in that position.

45. The fundamental principle, here illustrated by a simple example, is carried out into very great elaboration.

46. Derailing switches. To prevent collisions due to an engineer inadvertently passing a signal showing "stop", a "derail" is frequently employed where practicable. This is usually a half switch (the inner "point"), which, when "open", is sufficient to gide a train off the rails and onto the ties; or, where elaborated for passenger traffic, it may be a complete switch leading to a side track buried in sand, or provided with other means for stopping

the train with a minimum of damage. Such a derail is so interlockt with switches and sigs as to prevent its being "closed" for normal running, unless all other related switches and sigs are so set as to make it safe to do so. The derail produces a very wholesome effect upon any tendency of the engineer to "take chances" or even to forget a signal set at danger.

47. Scotchblock. Other derails, commonly used on freight sidings, etc, consist of a movable metal piece, so shaped that when placed over the rail, it will lift and gide the flange over the rail to the outside of the track.

48. Switch-locking. Fig 23, (not drawn to scale, and showing essentials only). In addition to the switch lever, there is usually provided a locking lever, which can thrust a pin, *A*, thru either one of two holes in the bar, *B*, only when the switch-points, *C* and *D*, have made their complete movement in either direction. If, as by an accumulation of dirt or of ice, the switch-points have not been brought home, neither hole in the bar, *B*, is brought opposit the pin, *A*, and the pin cannot enter the hole; and, since the locking lever is in turn interlockt with the signals, these can-

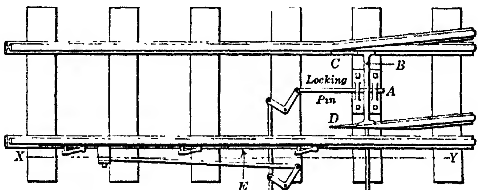

Fig. 23. *Plan*

Fig. 24. *Sec. along X-Y*

not be cleard. Connected with the locking lever, is also a

49. Detector bar, *E*, Fig 24, which is so connected with the locking lever that the bar must rise above the head of the rail as the locking lever is moved. This it cannot do if there are wheels on the switch. Thus, it is practically impossible to change the setting of a switch while a train is passing over it.

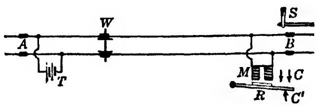

Fig. 25.

50. The Track Circuit affords a ready means of safely accomplishing many automatic sig operations, and much interlocking, or its equivalent; displacing many block sig towers, and clumsy and unwieldy all-mechanical interlocking plants. The fundamental principle of the track circuit is shown in Fig 25, which shows the two rails of a single track in a "block" or other section, *A B*. This section is electrically insulated from adjoining sections by heavy wood or fiber insulated fish-plates, indicated at *A* and *B*.

At one end of the section, is a battery, *T*, one wire of which is connected with one rail, and the other wire with the other rail. At the other end of the section is an electro-magnet, *M*, similarly connected. The armature, *R*, of this magnet, carries one or several contacts, some of which, *C*, are made, and some, *C'*, are broken when the armature is attracted by the magnet.

51. Let the track circuit, *A B*, be complete, and let there be no cars on the track. Then the current, from the battery, *T*, energizes the magnet, *M*; the armature is drawn toward the magnet, and the upper contacts, *C*, are closed, clearing the signal, *S*, at *B*. But if a train, or any pair of wheels, *W*, is on the rails between *A* and *B*, the current from the battery, *T*, will be short-circuited thru the wheels, back to the battery, thus robbing the magnet, *M*, of current, and causing its armature, *R*, to drop, and the sig, *S*, to show "stop". Also, if, thru accident or otherwise, the circuit is broken anywhere, if any short-circuit occurs, or if the battery fails, or if any metallic object touches both rails betw *A* and *B*, the sig will show "stop".

52. **The adjustment** is such that, normally, the current, energizing the magnet, *M*, will suffice to attract the armature, *R*, in spite of losses thru ballast, water, snow and ice, altho the practically total short-circuiting, caused by a pair of wheels, *W*, betw *A* and *B*, will certainly drop the armature, and set the sig at "stop".

53. **Stray direct currents** from nearby electric roads, or the direct return currents of electric roads themselvs, when the rails are used for track circuits, may "clear" the signal when it should not be cleard; but the use of alternating currents, for signaling, practically removes such danger

54. **The Relay,** *MC*, Fig 25, connected with the track circuit, is usually made to serv a number of purposes simultaneously, by means of its several contacts. When the armature drops, it may break several circuits and set several signals to "stop", and it may also share in

55. **Electric interlocking.** Where electricity is used for the control, and either electricity or air is used for the power to operate, the switch and sig levers control merely the making and breaking of electric contacts and operate a comparativly small interlocking machine; and are therefore usually less than a foot long. In different makes, the levers move in different ways. But the main features are common to all types.

56. **Train interlocking.** The mere presence of a train, on any section of track provided with a track circuit, may be arrangd, thru its relay, to break the circuits of any sig or sigs leading to that track. This does away with the necessity for the clumsy "detector bars" at switches.

57. **All-pneumatic interlocking** has been used to some extent, in which valvs take the place of electric contacts, and diaframs or pistons take the place of magnets and armatures.

Train-controld signal operation

58. **Automatic Signals** have proven very successful. They depend primarily upon "the track circuit", paragraph 50. When the head of a train enters a block, the sig it has past immediately shows "stop" against any train that may follow. When all of the train has past onto this block, the second block and sig behind it are "cleard". This sequence is produced automatically, and is continued indefinitely from block to block, operating distant sigs as well. Moreover, the mere presence of any train, or even of a pair of wheels, on any part of the track of a section of track circuit, will maintain at "stop" any sig or sigs governing any entrance to such section. In the best practice, as shown under "Electric Interlocking", ¶ 55, the track circuits are interlockt, thru relays, etc, with any switches or crossings that would be

involvd. If a train has enterd a block, no siding switch can be opend leading into that block; and conversely, once the block is cleard, and a siding switch is opend, all sigs leading to the section will show "stop".

59. Single-track Automatic. Automatic signals, as they were at first applied to single-track operation, would permit two trains at opposit ends of a stretch of single-track, to leav their sidings and run toward each other, where the single track, between sidings, was long enough to contain a number of blocks. No collision would result, however, because each train sets or holds, at "stop", not only the sigs which it passes, but also enough of the opposing signals *ahead* of it, to prevent collision; but one train or the other would eventually have to back out to the siding it had left.

60. "Absolute-permissiv". In this system, however, a train, entering either end of a length of single track, will hold, at "stop", *all* the opposing sigs ahed of it in that length. Other trains may follow it, as in ordinary double-track automatic signaling.

MISCELLANEOUS

Reliability

61. Reliability of railroad sigs generally has been developt to a very high degree. All devices, as far as possible, are so arranged that any conceivable failure will cause the sig to show "stop".

Indicators

62. Indicators of various types are used, and for several purposes. They are usually miniature models of sigs or switches or track, and indicate to the signalmen or yardmen the condition or position of the objects represented, but which may not be visible.

Other Methods

63. New methods of train control, by means of sig apparatus, are being developt, along lines radically different from those here described, and based upon other fundamental principles. These involv, in the main, various combinations or developments of the automatic stop, (¶ 64) time or speed control, and cab sigs. Some of these methods are in highly successful use; but, as this portion of the art of signaling is in a transition state, we refrain, for the present, from discussing it more fully.

64. Automatic Stop. The effect of the aut stop, upon the motorman, is similar to that of a derail (¶ 46). If he does not stop before reaching either of these devices, he is almost surely detected and disciplind; whereas, otherwise, he may repeatedly pass a sig, undetected, until the habit is developt to a dangerous degree The high cost of the aut stop, and dout as to its reliability under the severe weather conditions existing upon exposed steam roads, have retarded its adoption for such servis

65. "Smash" signals are sometimes used at the approaches of draw-bridges and at other particularly dangerous points. A smash sig consists of an arm or board, which extends out over the path of the car at such position as to clear trains when it shows "clear"; but, when set for the "stop" position, it will strike some part of the locomotiv or car. The impact smashes the sig (whence its name) and may likewise leav a mark on the loco, thus identifying the guilty driver.

66. Street and electric railway signals. The increasing size and speed of street and interurban electric rolling stock, have made desirable the replacement of primitiv methods by high-grade apparatus The use of the rails for the return of the power current, however, makes track-circuit signaling either unreliable or expensiv; so that it has been usual to utilize the passage of the trolley wheel under a special contact placed on the trolley wire, for setting the sigs.

67. Fig 26 represents a block of single-track line, with a sig and passing-place at each end. When the block is clear of cars, the apparatus is "neutral". Suppose now a car to be approaching from the left. Passing under the "contactor", at *B*, this car sets the sig, *E*, at "proceed", at the same time setting sig *F* (at the far end of the block) at "stop", and advancing a "counting wheel", at each sig, one step or notch.

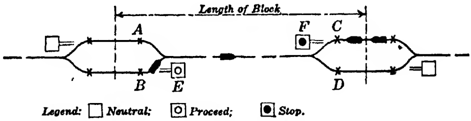

Fig. 26.

68. Sig *F* being now at "stop", no cars may enter the block from the right; but a following car, approaching from the left, may enter the block past the "proceed" sig at *E*, the motorman, however, regarding it as a caution sig, and observing that it "blinks", indicating that his car has been "counted in" And so on, with any other following cars, arriving from the left

69. But, as each car leaves the block, passing the contactor, *D*, the counting wheel at each sig is set back one notch or step; until, when the last car has left the block, the wheels have been set back to zero, and both sigs, *E* and *F*, are autom'y restored to "neutral".

70. Among recent refinements are devices for preventing the showing of "proceed" indications at both ends of a block simultaneously, even tho two cars, at opp ends of the block, make their respectiv contacts simul'y; for ensuring proper counting, even when reverse movements are made, for preventing disturbance of the counting wheels thru throwing off or restoring the power current; for applying the syst to single-track block sigs with overlap; and for the extension of the syst to include movements from a third point, as a siding.

71. Selectiv signaling enables a train dispatcher to set any one or more of a large number of sigs, visible or audible, and thus to get into communication with some one or more station agents or train crews.

72. The dispatcher is provided with apparatus with which he can send out, over a wire (which connects with all the sigs), electrical impulses at accurate predetermind intervals; or predetermind combinations of impulses, as in fire alarm systems. Each sig is differently adjusted to respond only to a given kind of impulse.

73. If the sig is a visible one, it is set to show "stop", sends a "return indication" or "answer-back" to the dispatcher so that he may be sure the sig has been set, and is autom'y lockt in that position. It can be set to "clear" only with the co-operation of the dispatcher. The conductor of a train that has been stopt by the sig, telefones the dispatcher; and the dispatcher, when satisfied that his instructions hav been understood, so operates his apparatus that the sig is unlockt, enabling the conductor to "clear" it.

74. Highway Crossings Alarms. The alarm itself may be either a bell or other sounding device, or lights or illuminated signs, or both. The alarms are usually controld electrically by means of track circuits, and various complex arrangements of relays, often interlocking with each other.

75. A crossing sig, utilizing the vertical flexibility of the rails, eliminates most of the difficulties due to irregular train movements, etc, and provides its own actuating power. The device is "direction sensitiv", requiring a train movement in the right direction to giv the alarm, and the alarm stops autom'y when the train stops.

76. Use of signals, January 1, 1911 and 1915, as given by the Interstate Commerce Commission.

(A "*line*-mile," or *road*-mile, = a mile of *roadway,* whether occupied by one track, or by two or more tracks. A "*track*-mile" = a mile of *single* track Thus, there are *two* "*track*-miles" in a "*line*-mile" of *double* track.)

Kind of signaling	In use, in 1911, on		In use, in 1915, on	
	Line-miles	Track-miles	Line-miles	Track-miles
Exposed disc	323	537	257	391
Enclosed disc ("Banjo")	1,921	3,866	1,356	2,961

Electric train staff	346	347	388	407
No of block sig stations		9,912		11,496
No. of block sig stations closed part of time		3,751		5,799
Number of block sections		29,881		51,690

77. Costs of sigs, prior to 1911, as given by Special Committee on Relations of Ry Operation to Legislation, 1911, Nov. 14, as result of enquiries and replies receivd from railroads operating about 80% of all track in U S equipt with block signals. From Ry Age Gaz. '11 Nov. 17.

Installing, per mile of track;
 Automatic, $1,146; Non-automatic, $248.

Maintaining, automatic, per year;
 $169 per mile of track; $69 per signal blade.

Costs for installing during 1911 were 10 to 40% greater than above, due, probably to the introduction of greater refinements.

*Substantially correct, notwithstanding insignificant discrepancies betw diff tables in the I. C. C. Reports.

YARDS AND STATIONS

1. General. Yards, stations and terminals* consist of tracks in addition to those of the main line; buildings and various facilities, for expediting the shifting and general handling of locomotivs, cars, freight, passengers, baggage, etc. They may consist merely of a small station, a single siding and a freight house; or may include large freight and passr stations, and dozens of tracks, and cover an area a mile or more in length

YARDS.

2. Definition, (Am Ry Eng Assn). "Yard.— A system of tracks, within defined limits, provided for making up trains, storing cars, and other purposes, over which movements not authorized by timetable or by train-order may be made, subject to prescribed signals and regulations."

3. General. Yards consist usually of

(a) a *Receiving Yard*, ¶ 10, upon which trains, entering from the main line, may remain until they can be sorted,

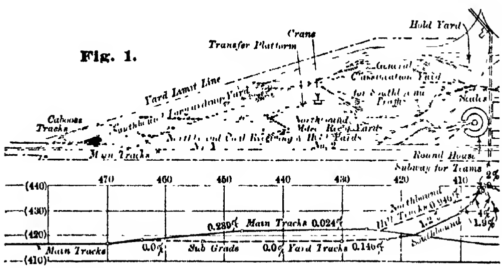
(b) the *Service Yards*, ¶ 11, in which locomotivs are coald, refrigator cars iced, etc, and rolling stock repaird,

(c) the *Separating, Sorting*, or *Classification Yard* proper, ¶ 46; and

(d) a *Forwarding Yard*, or *Departure Tracks*, ¶ 79, on which the newly made-up trains may wait before passing out onto the main line

4. The design of the yard, will depend largely upon the character, direction and amount of traffic, upon the area and shape of ground available, upon the nearness of various supplies and facilities, and upon other factors Large yards should be designd only in the light of all obtainable information on those and any other

Fig. 1.



pertinent points, and after carefully estimating future traffic and growth.

5. Example. The Missouri Pacific yd, Fig 1, at Dupo, Ill, is fairly representativ of the average ideal large yard for traffic about equally balanced.

6. Two directions. Usually, at any one place, there will be virtually two yards, one for each direction of traffic, except that there should be but one *service* yard, serving traffic in both direc-

*See foot note, p 1006.

tions. The two yards may be of approx equal, or of very unequal size, depending upon the relativ amounts of traffic in the two directions.

7. Main Line Tracks should, in general, especially in large yards, be located outside the yard, one on each side, if possible, or both on the same side if necessary; while facilities (service yard, etc) should be groupt near the center of the yard.

8. Connection with Main Line. The number of switches leading directly from the main track should be a minimum, with a cross-over if double-track in a small yard, the several *yard* tracks connecting only with *each other.* Any switches should, where possible, face away from the traffic, so that main-line trains will trail thru them, thus reducing the risk of "running into an open switch." The switch should also be interlockt with any main-line signals, and have a derail, pp 825-7, to prevent cars from wrongly getting onto the main-line.

9. Use. Freight yards are used (1) for the storage of rolling stock not in use, (2) for holding cars while being loaded or unloaded, and (3) for re-arranging or sorting cars When used for the latter purpose, they are commonly called "classification yards," are probably by far the most important, especially at large centers, and not only usually include the other two types, but serve largely to reduce their size. Various writers emphasize the importance of regarding a yard as a place in which to *handle* cars, and *not* as a place in which to *store* them.

Receiving Yards.

10. The receiving yard must be long enough to hold the longest train, and must have a number of tracks sufficient to hold all the trains coming until they can be handled. From it, the loco of each train is taken to the service yard for re-coaling, etc, and the train is pusht into the classification yard proper.

Service Yards.

11. Service yards should, in general, be centrally located. They should be provided with tracks and other means for changing cabooses and locos and for removing and holding disabled or "bad

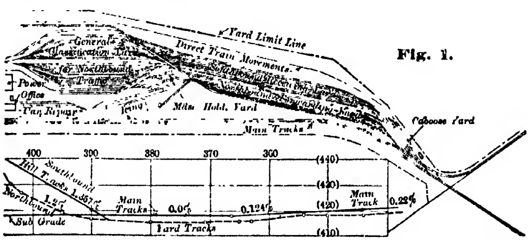


Fig. 1.

order" cars, and with running tracks to enable cars and locos to pass freely around or thru the yards. Facilities should be provided: for removing ashes from locos; for supplying them with water, coal and sand; for cleaning, oiling and housing them and making minor repairs to them; for inspecting and repairing cars and overhauling (hot) journal boxes; for cleaning passr cars; for icing refrigerator cars; for supplying water and feed to live-stock; and for such other special requirements as may exist.

12. Damaged cars of the dump or hopper-bottom type, and their contents, are sometimes conveniently handled by first running them up on a trestle and dumping their contents into good cars on tracks under the trestle.

68

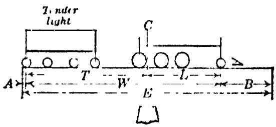

Fig. 6.

25. The table above shows weights and hor dists (to the nearest inch) for this and for two other types. The first two are the heaviest of those types made by the American and Baldwin works respectivly, up to 1912. The committee* recommends a min length of 75 ft for ordinary practice, and 90 ft for heaviest engines; preferring wyes to turntables longer than 90 ft.

26. *Mechanics. Moments and shears.* Stresses and deflections. When a turntable is "balanced," with or without load, the frame is to be treated as forming two cantilevers, each consisting of two parallel girders or trusses, *G*, the two cantilevers being connected over the central pier. For this case, but one position of the live load is possible. But, when the load is so placed that one wing of the table frame rests, at one end, upon the circle rail, *R*, and the other end upon the central pier, *C*, (as when a loco is entering or leaving the table), that wing is to be treated as a simple beam, and the other wing as a cantilever, and this is always the case with the non-tipping table, Fig 3. In either case, the moments and shears, for dead load, for live load, and for both combined, are to be found (for different positions of the live load) as on pp 440 to 453, the corresponding stresses as on pp 466, etc, and the deflections as on pp 480-481. For balanced table, the end deflections should not exceed about 1/2 inch, and must not bring the table to a bearing on the circle rail *R*.

27. According to the committee,* the practice is to use *unit stresses* of 16,000 lbs/sq inch in tension, and 10,000 in shear, when separate provision is made for impact (see Trusses, p 758); and the committee recommends 10,000 and 6,000 respectivly when no such provision is made; except that, at the ends, live load stresses should be doubled to provide for impact.

28. *Wheel loadings.* In designing a turntable, the locos, which may have to use it, should be studied, and the design should be based upon *that one which produces the greatest stresses.* By reason of their short wheelbase, *Cooper's loadings* (loco + tender = 48 ft for all classes; see Truss Specifications, p 755) are unsuited for modern heavy turntables; but they are nevertheless

*Report, Am Ry Bridge & Bldg Assn, 1912. To this committee's elaborate report, adopted Oct 1912, we are indebted for much of the information and recommendations here given.

Lengths, to nearest inch

sometimes used; their wheel-spacings being increased for the purpose. In the following table, the three heavier locos, by distributing their loads over a greater portion of the span, will, if placed upon a *bridge*, produce approx the same stresses as will the lighter Cooper E 50; but, on a balanced *turntable* (where each wing acts as a cantilever) their greater lengths and weights produce, at the center, greater shears and much greater negativ moments, as shown:—

Loading	Loco lbs	Tender lbs	Wheel-base, loco + tender	Moments and shears at center, in *turntable*		
				Neg mom ft-lbs.	due to Cooper	Shear, lbs

Mal	483,000	186,400	88' ½"	7,228,000	E 170	346,900

29. *Turning.* Small tables are turnd by hand; for which purpose a lever, 8 or 10 ft long, at convenient height, and fitting into a staple, is provided at each end of the table. Heavier tables are turnd by pneumatic power, or by gasoline or steam engins. Electric power is preferd, where readily available. Comprest air is used where occasional freezing, necessitating the temporary use of manual power, is not prohibitory The motor is placed sometimes next to the center, *C*, sometimes next to one end of either wing, sometimes at the end of a light wing at right angles to the main wings. With motors, tables are commonly turnd unbalanced, *i. e*, with the live load bearing partly upon the circle rail, *R*. Where ordinary tables are to be turnd without being balanced, and in non-tipping tables, it is usual to make the wing ends and their wings extra heavy, to support that part of the live load which comes upon them Balancing tables may then be turnd "balanced" when turning the shorter locos, and "unbalanced" with larger locos. Non-tipping tables, owing to the greater leverage of the resistance at their end supports, are difficult to turn, and expensiv in maintenance on account of wear in those supports.

30. Turntables are *held in position*, for passage of locos to or from them, by numerous devices; as by power brakes (especially where power is used for turning); or by bars, swinging vertically about a hinge fastend to the table ties, and catching, as they swing, in a notch fastened to the ties between the rails of the approach tracks; or by sliding latches, running in sleevs upon the table ties and entering sockets fastend between the rails of the approach tracks. The last-named are conveniently thrown into and held in the lockt positions by springs, and withdrawn by means of a hand-lever, which may withdraw simultaneously the latches at both ends of the table. The locking device is frequently connected with a signal, indicating its position.

31. *Crossing of the radial approach rails of adjacent tracks,* near the table, together with the use of frogs, is frequently necessitated by limitations as to space.

32. *Flooring.* The entire pit is now floored over only in special cases; as where floor space, or a passageway for teams, etc, is needed; or where danger of *freezing* is a serious matter; in which latter case, a stove may be mounted upon the swinging girders. A steam-pipe is sometimes laid around the pit, adjoining the circle rail, *R*, (Fig 2). The flooring, when used, is supported upon light radial trusses. Commonly the table is made wide enough to accommodate a *footway* on one or both sides, the footway being supported upon extra long ties, placed at intervals; and the footway is sometimes provided with a hand-rail. Frequently one or two light additional wings are provided, at right-angles with the main wings, to carry the motor or the stove, etc, or for other purposes; forming a cross-shape in plan For rigidity, the ends of the four wings may be connected by struts.

33. *Height of rail.* The table is usually placed at such height that, unloaded, its rails are about ¾ inch above those of the approach tracks; so as to leave ¼ inch clearance betw the circle rail and the end-wheels of the table, when the ends of the wings deflect each ½ inch under a balanced load. The tops of the table rails should come flush with those of the approach tracks at that end over which a loco may be entering or leaving the table. Steel springs have been employd, to absorb the shocks occasioned by locos entering and leaving.

34. The *foundations*, of both pivot pier and circle wall, are usually of concrete; and of course must be very carefully laid (especially that for the pivot pier), in view of the very heavy service required of them. The pivot pier is commonly provided with a stone cap. Where rock bottom is not accessible, piles are driven under the pivot pier, under the circle rail and under the parapet wall. Those under the pivot pier are usually in a square, 4 to 7 piles on a side, and covering an area of from 12 × 12 to 16 × 16 ft.

35. *The circle wall* is usually of concrete (rarely of wood), with timber coping for the support of the stub ends of the approach tracks, and radial timber ties for the support of the circle rail. When either the approach rails or the circle rails rest directly upon the concrete, the latter is apt to be disintegrated The circle wall is usually from 6 to 7 ft in greatest *width*, and the *parapet wall* from 1.5 to 2 ft. Owing to its circular form, in plan, it acts as a hor arch, and a gravity section (capable of withstanding alone the collapsing pres of the surrounding earth) is not necessary.

36. *A niche*, or recess, left in the circle wall at some point, gives convenient access to the end of the table, for inspection etc.

37. *Wooden turntables* are sometimes used, from motivs of economy, especially for temporary purposes. They are sometimes without rollers or disks at the center, and then, in turning, bear either upon their end wheels or upon a series of wheels arranged in a circle not far from the center. In the latter case, the live load bears partly upon the end wheels when entering or leaving the table. They usually require two men, with crank mechanism, to turn them. Their economy, in first cost, is apt to be offset by excessiv cost for repairs.

38. *Pit drainage,* always important, is especially so with the deep pits often required for modern heavy locos. *Water, in the pit, rusts the bearings, and thus necessitates stoppage of operations and jacking up for cleaning and oiling. Water, freezing in the pit, may entirely stop operations. Where the pit bottom is too low for convenient drainage, the pit may be made shallower by one or other of the devices mentiond in ¶¶ 20-22.

39. Figs 7 and 8. **The center* is essentially a circular steel box,

*Report, Am Ry Bridge & Bldg Assn, 1912. To this committee's elaborate report, adopted Oct 1912, we are indebted for much of the information and recommendations here given.

the lid of which (carrying the frames) bears upon it usually thru the medium of conical rollers, ball bearings, or disks, of hardend steel; *conical rollers*, Fig 7, being most largely used. In the best tables, these are held in place, radially, usually by "live rings" encircling them, both at their inner and at their outer ends, and separated from them by ball bearings or frictionless washers. Conical rollers are commonly from 7 to 12 ins long, and from 4 to 8 ins diam at the larger end. They usually bear, above and below, upon relativly thin annular *track plates*, which, when worn, may be replaced, leaving box and lid intact. The design of the center is often left to the manufacturer.

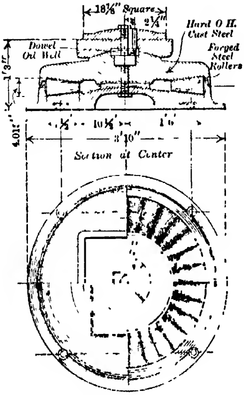

Fig. 7.

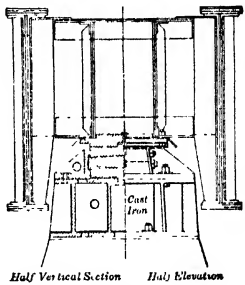

Fig. 8.

40. Notwithstanding the successful use of ***disk centers***, Fig 8, in swing-bridges, where they carry much heavier loads, they have not come into general use for turntables. The committee* recommends their serious consideration

41. *"Hydraulic" centers* (oil or glycerin being used, on account of danger of freezing, instead of water) have been suggested. They would be easily adjustable in height.

42. Centers or pivots are *very important*. It pays to use the very best obtainable. Three-quarters of RRs use conical roller or ball bearings, of manufacturers' standards. Much of the trouble with roller bearings seems to have been due to former poor design and small size, and to subsequent neglect in maintenance.

43. *The mechanism should be oild* at least annually, and as much oftener as may be required by flooding, or when the table becomes hard to turn. The frames, etc., require frequent painting. *To facilitate inspection*, repairs, etc., the table may be jacked up from the center pivot; the jacks resting upon two concrete foundations, placed diametrically on opposite sides of the center, and lifting by means of steel brackets, riveted to the table.

*Report, Am Ry Bridge & Bldg Assn, 1912. To this committee's elaborate report, adopted Oct 1912, we are indebted for much of the information and recommendations here given.

44. *The cost* of turntables varies widely with many factors, but the following may be taken as approximations. Cost of steel deck *turntable, complete,* with tractor, including pit, pier, etc., $100 per linear foot; thru tables, $150 Light *wooden* tables may cost as little as $15 to $20 per lin ft. *Pit,* lined, including pier foundation, from $0.50 to $1.30 per sq ft; *paving alone* (often omitted), from $0.15 to $0.25 per sq ft.

45. Wyes or Y-tracks. See Turnouts, ¶¶ 18, 19, p 825.

Classification Yards.

46. The main object of a classification yard is to receiv, from one or more points or lines, as *A, B, C, D,* etc., trains in each of which there may be cars for any or all of a number of other points or lines, as *M, N, O, P,* etc, and so to rearrange the cars as to make up new trains, the cars of each of which may then go directly (or with a minimum of re-arrangement or subsequent shifting) to their respectiv destinations, as *M, N, O, P.*

47. Minor objects are the similar re-classification (or "Transfer") of the *contents* of cars, and general renewals and repairs.

48. Push and pull, or flat shifting. Where gravity cannot be utilized for shifting (¶ 50), car movements must be made by locomotiv Cars may be given a *push* by the loco. and then left to go where they are wanted, sometimes assisted by a slight down grade. They should be under the control of a brakeman. Or, the cars may be *pulled,* "making flying switches," as follows:—With the train in motion, the loco is uncoupled, and runs on ahead, at increast speed, thru a switch, on to an unoccupied track; and the switch is then quickly thrown, in time to send the oncoming cars onto the required track. This requires skilful co-operation of crew and yardmen These methods, tho objectionable, and expensiv *during* operation, will, nevertheless, be usually more economical in a small or unimportant yard, than any of the following methods, which are more costly to install and maintain, but which may be well worth their cost in large or busy yards.

49. Poling. By means of a stout pole, two or three times as long as the clear space betw cars, the loco (sometimes provided with a specially constructed car, and running backward and forward on a parallel track) pushes off, from a train, one or more cars at a time, sending them, thru switches, to their destinations under their own momentum.

50. Hump or gravity classification yard

In this type of classification yard, the train is pusht up over a hump in the track, at which point the cars are uncoupled, one or more at a time, and descend, by gravity, thru the yard, to their desired destination.

51. Operation. A train enters the receiving tracks, its locomotiv is uncoupled and sent to a side track for re-coaling, etc. A special yard loco then comes up behind the train and pushes it slowly forward, over an up-grade, to a summit or "hump." As each car, or set or "cut" of cars for any one destination, passes over the hump, it is uncoupled. It then proceeds, by gravity (usually first over a track-scale, on which each car may be weighd) down quite a steep grade and onto the "ladder track," which leads by switches to the several classification tracks. As each car or "cut" starts on its way, it may be markt with a number or symbol, indicating its destination. As the car or cut comes down the ladder track, its destination, as thus markt, is noted by switchmen, who set the switches for it. It is boarded by a brakeman or "rider," who then controls its speed by means of the brakes, the grades of the ladder and classification tracks all being such as to insure the delivery of the car to the furthermost points desired. The rider then returns for another car or "cut" When it is time to make up a train from one or more classification tracks, the "road engin" backs in from the lower end of the yard, couples to the collections of cars desired, and then proceeds into the forwarding yard or out onto the main line.

52. Speed of operation. According to Mr. C. L. Bardo, Jour N Y R R Club, 1903, Dec, a train of 60 cars, with 50 cuts, requires by push and pull, 2 hours; by poling, 1 hour, 15 mins; by hump, 30 mins.

53. Grades of hump yards depend chiefly upon the av and max car resistances (usually greater in empty than in loaded cars) per unit of weight; which, in turn, depend upon length of time cars have been standing; upon temperature (the resistances being greater in cold weather); upon prevailing wind direction, or that of probable max winds; and upon condition of track, including curvature. See Train Resistance, pp 1057, etc.

54. In the following table, the first line gives the recommendations of the Am Ry Eng Assn Manual, 1911. The others (from Ry Age Gaz, 1912 Aug 9, pp 236-9) give max, av and min values reported by Mr Shelby Saufley Roberts, representing about thirty hump yards. The grades are given in ft per 100 ft.

	First grade from summit	ladders	classificatn yard
Am Ry Eng Assn	3.00	1.00	0.50
S. S. Roberts Max	4 00	1.75	1 00
" " Av	2 66	0.97	0.30
" " Min	1 00	0.50	0.00

55. *Seasonal changes.* In order to compensate for the markt differences in resistance, due to temperature, hump grades are sometimes changed, either by re-grading the hump portion of the track twice each year, or by providing two humps, side-by-side; a steeper one for winter use, and a flatter one for summer use; but the steeper hump may be advantageously used in summer for hard-running empties. For a third method, see next ¶.

56. The *mechanical hump,* designed by Mr. A. W. Epright, scale inspector, Penna R R, consists essentially of a short two-span girder bridge, the middle support of which may be raisd or lowerd by means of jacks, and then held at the desired height by blocks. In one installed at West Brownsville Junc, Monongahela Div, each span is about 20 ft, and the central support movement is about 8 ins.

57. After passing over the hump, it is usually desirable to pass the car over a

58. Track Scale. Until quite recently, very little attention appears to have been given to the design of track scales, with the result that they have been rather delicate affairs likely to get out of order, and to give erroneous readings. Later efforts, however, have produced much more satisfactory machines, altho they do not appear to have been generally standardized. They are essentially large weighing machines, on the platform of which the track is laid.

59. *Difficulties* that obtaind have been listed as follows by a committee of the Am Ry Bridge & Bldg Assn.

Carlessness of weigher; improper balance, another car partly on scale Weakness of scale; deflection of scale bridge or levers.

Misc: deck binding, rails binding, broken castings or bearings, dull bearings, bearing feet resting on angle irons, insuff clearance betw feet and scale timbers, levers out of line or loose, and foreign matter in friction with levers or scale parts. See also ¶ 63.

Many of these troubles are due primarily to insufficiently firm foundations.

60. *Dead rails.* To avoid unnecessary wear of scales, locos and cars not requiring to be weighd may, as either approaches the scale, be switcht across the scale pit, on a pair of "dead rails," laid parallel with the weighing-rails and about six ins from them, but supported rigidly on posts which pass down thru the scale without touching it and rest upon the scale-pit foundations; but modern track scales are sufficiently strong to carry all the traffic without

injury; and dead rails are going out of use, all cars and locos passing over the weighing-tracks. The dead rails endanger the trackmen, whose feet may be caught betw them and the weighing-rails, and their supports obstruct access to the scale mechanism.

61. *"Bridge-rails."* The weighing-rails are sometimes connected with the fixt rails, at each end of the scale, by short rail lengths, pivoted to each. These not only obviate the blow caused when a wheel jumps the gap betw the ends of the fixt and the weighing rails, but also transfer the load more gradually to the scale.

62. *Relieving gear* The Penna R R has employed a device, patented by Mr. A. W Epright, and consisting of a system of toggles and pistons, operated by either air or water, and under control of the weighmaster by means of a three-way valv, by means of which, in a second, betw the passage of any two cars, the load of the scale and any following car may at pleasure be taken by the toggles, or restored to the scale levers

63. *Binding of platforms* has been a frequent source of trouble and may be prevented by careful construction, by preventing inward bulging (as by frost) of the pit sides, and by so beveling the opp faces that the space, betw them, widens downward, in order that objects, falling into the space, shall not wedge and bind. Rail ends, even when properly secured against creeping, are apt to bind, under temperature changes; but this may be prevented by inserting switch-points in the rails near the scale ends.

64. The *scale length*, if each car to be weighd is to be stopt ("spotted") on the scale, should be about the length of the longest car If cars are to be weighd in motion, as they run over the scale, the scale length should be about one-third greater.

65. *Testing* Scales should be tested periodically, say every few months, by running over them, and stopping on them at various points, special loaded test cars of known weight Preferably, the weights should be adjustable, in order to see whether the indications of the scale are truly proportional to the load, for all weights likely to come upon it. Many railroads have special cars for this purpose.

66. *Drainage, heating and lighting* of the scale pit are all desirable to prevent damage by water and by freezing, and to facilitate inspection and adjustment.

67. *Speed of weighing.* The velocity of the cars over the scales, while being weighd, may vary between zero and 6 or 8 miles/hr, about 4 miles/hr being usual. It is usually practicable to weigh several cars per min; but the time required, per car, may range from several mins, down to abt 8 secs, tho this high rate can seldom be maintaind continuously.

68. Classifying. As the cars are cut off from the train, and as they pass over the hump, the switchmen must know for which track each cut is destind, in order that they may set the switches properly; and the brakeman of each cut must know this also, in order that he may properly control the speed in passing around the switch and in coupling on to any cars ahead. Sometimes the destination is chalkt upon the car bodies; sometimes (especially at night) the brakeman informs the switchman by means of arbitrary signals.

69. The *"cut list,"* recommended by the Am Ry Eng Assn, Supplement of 1913, Manual of 1911, consists of two or more duplicate lists, giving (1) the number (1st, 2nd, 3rd, etc) of the cut, (2) the number of the track to which the cut is destind, and (3) the number of cars in the cut A copy of the list is given to each switchman concernd and (if thought necessary) a copy to the brakeman of each cut.

70. *Yard switches* (Am Ry Eng Assn, Manual, 1911) for ladder tracks should have *frogs* not sharper than No. 8. See also ¶ 57 (Ladders) under Turnouts, p 871.

71. *Switch operation.* The operation of each switch by a lever placed at the switch, in the yard, is cheap in installation, but expensiv in operation, and inefficient in a large yard, as compared with control of numerous switches from a single switch tower by means of the usual switch and signal operating equipments. See Signals, pp 985, etc.

72. *Curvature compensation.* As grades, on the line, are reduced on curvs, to facilitate hauling upgrade by locos. so they are increast on curvs in gravity yards, to aid gravity in getting the cars around the curvs. See ¶ 41, under Train Resistance, p 1062. Mr. H M. North, of the L S & M S Ry, recommends an increase of about 0 05 ft per 100 ft (1/20 of one per cent) for each degree of sharpness.

73. **Ladder tracks** are those containing the switches leading to the several classification tracks (¶ 74). In small yards, one ladder track suffices, but ordinarily space is wasted when more than 8 or 10 tracks are taken from one ladder, and it is then advisable to use two or more ladders. See also "Ladders," ¶ 57, under "Turnouts," p 871.

74. **Classification tracks** are long parallel tracks, onto which cars are run from the ladders. In general, each classification track represents a diff route or destination or purpose of train Thus, track No 1 may be used for cars destind for the M R R, track No 2 for cars of the N R R, and so on; or track No 1 for cars bound for station *P*, track No 2 for station *Q*, etc, one train being subsequently made up by taking the cars successivly from tracks 1, 2, etc, in such order that they may be cut off at stations *P*, *Q*, etc, as the train proceeds, and without re-shifting; or track No 1 may be reservd for a regular train, to leav at a specified time; track No 2 for a special train; track No 3 for empties, to be returned when enough of them have accumulated to form a train; etc, etc

75. **Secondary classification** yards are used where the desired classification, especially as regards the order of the stations, cannot be attaind in the main classification yard. Such a yard is conveniently placed beyond the main classification yard, and may have a "hump" of its own These yards are called also *"reclassification yards," "station-order shifters,"* or *"grouping yards."*

76. **Capacities** of classification tracks. No such track need be longer than the longest train to be assembled. Indeed, if they be made somewhat shorter, the occasional slight inconvenience of having to make up a train from cars on two tracks is usually more than compensated by time saved in dropping cars into places from the hump, in the return of brakemen, and in general communication and operation.

77. **Spacing** of yard tracks Recommendation of Am Ry Eng Assn, Manual, 1915; c to c, min; body tracks (main tracks of classfn yard) 13 to 14 ft; ladder track and first body track, 15 ft from any adjacent track. Min spacing must enable men to see signals and to avoid colliding with electric light poles, etc.

78. **Car riders,** car droppers, or brakemen. One "cut" seldom contains more than five cars, even when more than five are bound for the same place. Each cut is (or should be) controld by a brakeman, from the hump to near its destination. The return of the men to the hump involves fatigue and loss of time if they walk, and expense if they are carried. Their transportation may be effected by means of an old light loco with a car, or by gasoline inspection or electric cars. Moving sidewalks have been suggested.

Forwarding Yards.

79. The forwarding yard is placed beyond the classifn yards. Each of its tracks should be as long as the longest train. Often two or more trains can be accommodated on one track, especially if cross-overs are provided. Comprest-air pipes should be provided, for testing brakes while loco and caboose are being coupled up.

Thorofare tracks, thru or alongside the yard, permitting free and rapid movement of locos and cabooses, around and to the trains, should be provided.

Illumination.

80. Am Ry Eng Assn, Manual, 1911, recommends, for hump and ladder tracks, arc lights of 2,000 candle power each, 28 ft or more above ground, and 140 to 150 ft apart Other authorities recommend lights of lower c p, with closer spacing The use of reflectors or lenses, and of shields, etc, to direct the light efficiently, appears to be worthy of much more careful study than it has usually receivd.

81. When the main body tracks are not illuminated, a light may be left at the rear of each collection of cars, and shifted back to the rear of each new "cut" added.

STATIONS*

Freight Stations.

82. Transfer stations. As the classification yard serves for the rearrangement of the cars in trains, so the transfer station serves primarily for rearranging the contents of cars among the diff cars, transfering it from any one car to any others, over platforms adjacent to tracks upon which the cars are run The platforms are preferably placed flush with the floors of box cars, in order that trucks may readily be wheeld over planks laid across the gap betw car and platform Storage space (preferably coverd) should be provided, on the platforms, to receiv goods for which cars are not ready.

83. Mechanical handling (electric trucks, telfers, traveling platforms, etc) is economical, both in transfer and general freight work, in large stations, if sufficiently flexible and not too cumbrous. "Where large amounts of freight are to be transferd, the use of power-driven coverd traveling platforms is recommended," Am Ry Eng Assn Manual, 1911, p 401.

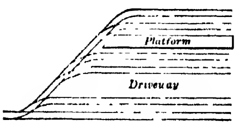

Fig. 9.

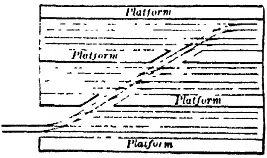

Fig. 10.

84. Freight Yards and Stations. The track layout is usually a mere series of pairs of parallel tracks, merging into one or more tracks from the main line or a classification yard, with spaces betw them, for teams or for platforms, as in Fig 9, the yards being open and the stations usually coverd. In stations, to save space, the main feeding track is often run diagonally thru the building, and the loading tracks are taken off as spurs in both directions, somewhat as indicated in Fig 10. "Inbound freight-houses should have a floor space of 50 ft width if practicable; out-bound, 25 ft." Am Ry Eng Assn.

*The Am Ry Eng Assn defines a *terminal* as "An assemblage of facilities provided by a ry at a terminus or at intermediate points on its line for the purpose of assembling, breaking up and relaying trains." To avoid confusion, however, we have refraind from using the word "*Terminal*" (except as below), and have used "*Station.*" A station that is *not a thru* station we call a "*Terminus*" (plural "*Termini*"), or a "Terminal Station."

85. Modern freight-handling devices permit economy in space by making it possible to build stations two or more stories in height; one story for inbound freight, another for outbound, and others for storage, etc; freight being transferd, upon and betw stories, by means of traveling platforms, barrel-hoists, belt-conveyors, elevators, and (for downward movements) straight or spiral shutes for non-fragile pieces, all in addition to the freight-handling devices referd to under Mechanical handling, ¶ 83.

The freight yard should have a traveling or other crane, for heavy pieces; and special apparatus (as clam-shell bucket-hoists for coal, grain elevators, etc) where much of one commodity is to be handled.

86. For team delivery yards, Am Ry Eng Assn (Manual, 1911, p 398) recommends stub tracks in pairs, 12 ft c to c of tracks, and, if practicable, not less than 30 ft c to c of pairs; tracks not more than 20 cars capacity; ingress and egress for teams at each end of each teamway; power crane, wagon scales and track scale.

Passenger Stations*

87. General. Some of the major points to be observd in station design are:—getting passengers, baggage and express to and from the trains with a minimum of delay and confusion, and, in termini,* getting the loco out of the way, turnd around, waterd and coald, and re-coupled to the train; also car cleaning, etc. Some car cleaning can be done in the station.

88. Platforms. To expedite the handling of passengers and baggage, it is recommended by the "Yards and Terminals Committee" of the Am Ry Eng Assn, 1911 March, that, if baggage platforms cannot well be provided in addition to passenger platforms on the same level, the baggage be transferd to and from another level by means of elevators so located as to keep it off the platforms as much as possible.

89. Ramps, or inclined passageways, as substitutes for stairways, greatly facilitate the movement of passengers in stations, and reduce liability to accident at rush hours. The Y & T Comm, Am Ry Eng Assn, Mar 1911, recommends a grade not exceeding 1%; but considerably steeper grades are successfully used. The surface must be sufficiently rough to avoid danger of slipping.

90. Lanes of travel. Often much can be done to reduce congestion in the layout of the station and passageways, by preventing crossing of lines of travel of passengers, keeping such lines parallel as far as possible.

91. Future requirements. Owing to the difficulty and expense involvd in reconstructing a large station when its traffic begins to exceed its capacity, the requirements of the future should be estimated for 20 years ahead, if possible, and provided for in the design of the station.

92. Large vs numerous smaller stations in large cities. Handling, at a single station, all or most of the passenger traffic of a ry at a large city, necessitates, on an average, a long journey to reach or leav the station, and much walking in the necessarily large station itself, to reach or leav the trains; and the alternativ of several smaller stations thruout the city, along the line, has been suggestd (as by Mr. Fred A. Delano, Pres Wabash Ry), even at the expense of some added time for additional stops of express trains.

---

*The Am Ry Eng Assn defines a *terminal* as "An assemblage of facilities provided by a ry at a terminus or at intermediate points on its line for the purpose of assembling, breaking up and relaying trains." To avoid confusion, however, we have refraind from using the word *"Terminal"* (except as below), and have used *"Station."* A station that is *not a thru* station we call a *"Terminus"* (plural *"Termini"*), or a "Terminal Station."

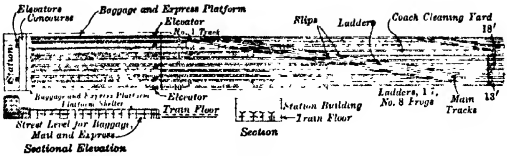

Fig. 11.

93. Plan. Fig 11 is a layout for a passenger terminal station, as recommended by a Comm of the Am Ry Engg Assn, March 1911;

Fig. 12.

and Fig 12 a station of the thru type. In the terminal station, two levels are proposed, one for passgrs and one for baggage and express, together with a simple and comprehensiv arrangement of ladder tracks, with car cleaning yard adjacent. This ideal arrangement would, of course, usually have to be alterd, on account of local restrictions. In the plan for the thru station, it will be noted that the two main-line tracks divide into 6 in all, affording two thru tracks in the middle (without deviation from their course), and two platform tracks (with an island platform betw them) on each side, thus giving ample loading and unloading facilities, without delaying trains not scheduled to stop at the station.

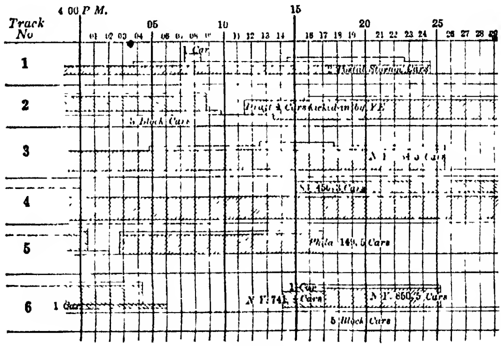

Fig. 13.

94. Study. Fig 13 shows part of a diagram recording the occupancy of the several tracks of the Penna R R at Broad St sta, Phila. (Mr. E. B. Temple, Asst Chf Engr) during a given period

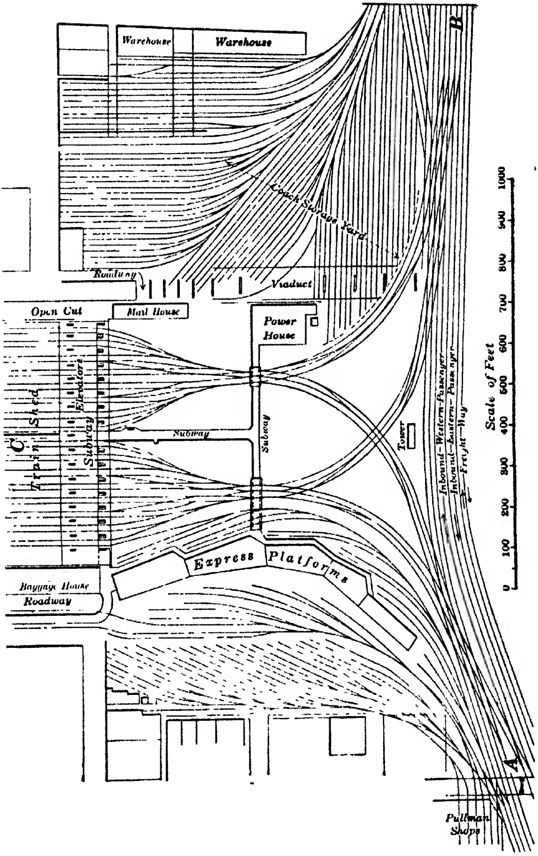

Fig. 14.

(4:00 to 4:30 p m, Jan 18, 1912; only 6 tracks shown). The entire diagram included the 16 tracks of the station, and coverd the period from 4 to 6 p m. Similar diagrams showd the conditions existing, during the same period, on portions of the yard. The several tracks are laid off to vert scale, end to end, their inner

ends down. The vert spread, allotted to each track, represents the length to which it may be occupied without fouling more than one line. Cars and locos are plotted as rectangular areas. The vert dimensions of the rectangles represent the lengths of track occupied by cars, etc; the vert positions of the rectangles represent the positions of the cars, etc, on the several tracks; and their hor dimensions and positions represent the periods during which the several tracks were so occupied. In practice, arriving and departing trains are distinguisht by diffs of shading of these rectangles; and kinds of cars and of locos by initials, as by "R.E." for "road engine." Similar diagrams have been used by the Belgian State Railways and at the Camden station of the Balto & Ohio Ry at Baltimore.

95. Fig 14, p 1009, represents a *"back-in" station.* A train, bound for the sta, coming, say, from *A*, proceeds first to *B*, and then backs in to the sta, as at *C*; thus enabling the loco to be promptly releast.

96. Speed of handling trains at termini depends largely upon the facilities provided for the rapid handling of locos, passgrs and baggage, and for cleaning cars, and upon the nature of the traffic and of the motiv power. Comparing 26 large American passgr stas the Y & T Comm, Am Ry Eng Assn (Eng News 1911, Apr 6, p 414), found that the number of trains actually handled during the busiest hour, ranges from 1 to 3 5 per av track (including movements on *all* tracks), and from 2 to 8 on the *busiest* track; while estimated possibilities ranged from 2 to 12. Some of the higher figures were those of thru stations.

97. Electric operation of trains greatly facilitates their rapid movement in termini, inasmuch as the motiv power need not leave the sta, or change its position, for reversal of loco or train, or for supplies. The tracks and yard are thus left largely free for complete train movements.

98. Rapid transit termini are frequently arranged with one or more *loop tracks,* around which the trains may be run without reversal of loco or motorman. This is often practicable with rapid transit equipment, which can readily turn sharp curvs, and a very large tract of ground is therefore not necessary for the loop.

Water Stations.

Water stations are points along a railroad, at which the engines stop to take in water. **Their distance apart** varies (like that of the fuel stations, which accompany them,) from about 6 miles, on roads doing a very large business: to 15 or 20 miles on those which run but few trains. Much depends, however, upon where water can be had. It has at times to be conducted in pipes for 2 or 3 miles or more. The object in having them near together is to prevent delay from many engines being obliged to use the same station. To prevent interruption to travel, they are frequently placed upon a side track. A supply of water is kept on hand at the station, usually in large wooden tubs or tanks, enclosed in frame tank-houses. The tank-house stands near the track, leaving only about 2 to 4 feet clearance for the cars. It is two stories high; the tank being in the upper one; and having its bottom about 10 or 12 feet above the rails. In the lower story is usually the pump for pumping up the water into the tank, and a stove for preventing the water from freezing in winter.

The tanks are usually circular; and a few inches greater in diameter at the bottom than at the top, so that the iron hoops may drive tight. **Their capacity** generally varies from 6000 to 40000 gallons, (rarely 80000 or more,) depending on the number of engines to be supplied. **A tender-tank holds** from 3000 to 7000 gallons; and **an engine evaporates** from 20 to 150 gallons per mile, depending on the class of engine; weight of train; steepness of grade, &c. Perhaps 40 gallons will be a tolerably full average for passenger, and 80 for freight engines. **The following are the contents of tanks** of different inner diameters, and depths of water. U. S. gallons of 231 cubic inches; or 7.4805 gallons to a cubic foot.

Diam.	Depth.	Contents.		Diam.	Depth.	Contents.

22	11	31277	4181	34	17	115451	15435

Cypress or any of the pines answer very well for tanks. The staves may be about $2\frac{1}{2}$ inches thick for the smaller ones; to 4 or 5 inches for the largest. The bottoms may be the same. The staves should be planed by machinery to suit the curve precisely. Nothing is then needed between the staves to produce tightness. A single wooden dowel is inserted between each two near the top, merely to hold them in place while being put together. The bottom is dowelled together; and simply inserted into a groove very accurately cut, about an inch deep, around the inner circumference of the tub, at a few inches above the bottoms of the staves.

One of 20 feet diameter, and 12 feet deep, may have 9 hoops of good iron; placed several inches nearer together at the bottom of the tank than at the top. Their width 3 inches; the thickness of the lower two, $\frac{1}{4}$ inch; thence gradually diminishing until the top one is but half as thick. The lower two are driven close together. These dimensions will allow for the rivet-holes for riveting together the overlapping ends; and for a moderate strain in driving the hoops firmly into place. Three rivets of $\frac{1}{2}$ inch diameter, and 3 inches apart, in line, are sufficient for a joint of a lower hoop. One of 34 feet diameter, 17 deep, may have 12 hoops; the lower ones 4 inches by $\frac{1}{2}$; with three $\frac{3}{4}$-inch rivets to a lower hoop-joint.

The bottom planks of the tank must bear firmly upon their supporting joists, or bearers.

A tank must have an **inlet-pipe** by which the water may enter it; a **waste-pipe** for preventing overflow; and **a discharge or feed-pipe** 7 or 8 inches diameter, in or near the bottom; through which the water flows out to the tender. The inner end of the discharge-pipe is covered by a valve, to be opened at will by the engine man, by means of an outside cord and lever. To

its outer end is generally attached a flexible canvas and gum-elastic hose about 7 or 8 inches diameter, and 8 or 10 feet long, through which the water enters the tender-tank. Or, instead of a hose, the feed-pipe may be prolonged by a metallic pipe, or nozzle, sufficiently long to reach the tender; and so jointed as, when not in use, to swing to one side, or to be raised to a vertical position, (in the last case it is called a drop,) so as not to be in the way of passing trains. The same tank may supply two engines on different tracks, at once. The tanks are very durable.

The patent *frost-proof* tank of John Burnham, *Batavia, Illinois,* is simply an ordinary tank, in which the water is prevented from freezing by means, 1st, of a circular roof which protects a ceiling of joists, between which is a layer of mortar; 2d, by an air-space obtained by a similar ceiling beneath the timbers on which the tank rests. *Although the sides are entirely unprotected, no house is necessary; but merely strong posts and beams on a stone foundation, for the support of the tank.** The supply pipes are in boxes made of boards and tar-paper.

Tanks are frequently made rectangular, with vertical sides of posts lined with plank, and braced across in both directions by iron rods. They are more apt to leak than circular ones. They have been made of iron; but wood seems to be preferred.

The water for supplying the tanks, may be pumped by hand, steam, horse, wind, hydraulic ram, or otherwise, from a running stream; from a pond made by damming the stream if very small or irregular; from a cistern below the tank; or from a common well. Many roads doing a business of 10 or 12 engines daily in each direction, depend entirely upon wells; and pump by hand; generally two men to a pump. Those doing a very large business, when the supply cannot be obtained by gravity, mostly use steam. **The windmill is** the most economical power; and when well made, is very little liable to get out of order. Of course it will not work during a calm; but this objection may be obviated in most cases by having the tanks large enough to hold a supply for several days. Steam, however, is most reliable.

The following table will give some idea of the **power required in a steam engine for the pumping.** In ordering an engine, specify not its number of horse-powers, but the number of gallons it must raise in a given number of hours, to a given height; with a given steam pressure, (say about 60 to 80 lbs per square inch.) The pump should be sufficiently powerful not to have to work at night; and should be capable of performing at least 25 per cent. more than its required duty.

A fair average horse should pump in 8 hours the quantities contained in the first 3 columns; to the height in the 4th column; or sufficient to supply the number of locomotives in the 5th column, with about 2000 gallons each. Two men should do about one-third as much.

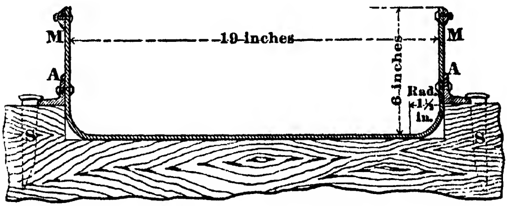
A reservoir, with a stand-pipe, or water column, is preferable to the ordinary tank, when the locality admits of it; being less liable than the pump to get out of order; and being cheaper in the end. The reservoir is supposed to be filled by water flowing into it by gravity; and to have its bottom at

*The cost of windmill alone, for railway stations, varies from about $450 for 13 feet diameter, to $1500 for 36 feet diameter, at factory.

least about 8 feet above the rails; or at any greater height whatever that the ground and the height of the water may require. It may be excavated in the ground; lined with brick or masonry in cement; with a bottom of concrete; or it may be built above ground, according to the locality. It may be roofed and covered in, or not; and it may be near the tracks, or at a considerable distance from them, according to circumstances. From its bottom, an iron pipe from 8 to 12 inches diameter, is carried (generally underground,) to within a few feet of the track. At that point it turns vertically upward to about 8 or 10 feet above the track, forming a **stand-pipe, or water-column**; from the upper end of which the water flows (through either a hose or a jointed nozzle,) as in the case of a tank. Several such pipes, or one larger one, may be laid, for the supply of two or more engines at once, through as many stand-pipes. Where the pipe makes its bend, and becomes vertical, is a valve for opening and closing it; and which may be worked by a hand-wheel placed at such a height as to be easily reached by the engine man.

On some of the more important lines, the **tenders of fast trains scoop up water, while running,** from a long **trough,** or **"track tank"** laid between the rails. The tanks are about ¼ mile long. They must of course be level, and they therefore require a level track.

As originally introduced in England, by Ramsbottom, the trough was of cast-iron, in lengths of about 6 ft. These were bolted together by means of flanges at their ends. The ends were not in contact with each other, but were separated by a strip of vulcanized rubber.



Our figure shows a track tank of $\frac{3}{16}$ inch rolled plate-iron, the sheets of which are 62 ins long. The lengths overlap each other 2 ins; leaving 5 ft as their *showing* length. The sheets are cut slightly tapering, so that at one end of each length the trough is $\frac{3}{16}$ in deeper than at the other, and the tops are thus kept flush with each other throughout. The joints are double riveted with ⅜ inch rivets, about 1½ ins from center to center, and staggered. At each end of the trough, the bottom slopes upward, and in a length of 6 ft, comes to the level of the tops of the sides. The cross-ties are notched, as shown, to receive the trough, which is loosely held to them by two spikes, S and S, in each tie. The heads of the spikes lit over the horizontal flanges of the 1½ × 1½ inch angle bars, A and A. M and M are mouldings of 1⅛ × ½ inch bar-iron. The angles and the mouldings are in lengths of 15 ft, and are riveted to the sides of the trough continuously throughout its length.

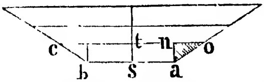
The **scoop** on the tender is **lowered** into the trough, **and raised** from it, by means of a lever on the fireman's platform, and is not permitted to touch the bottom of the trough.

The **trough is supplied** with water by means of pipes leading from an adjacent tank. The supply is regulated by a man in charge.

To prevent the water from **freezing in winter,** steam is led to the trough from the boiler of the pumping engine, through iron pipes laid under ground alongside of the track. These pipes are provided with branches which introduce the steam to the trough at every 40 ft of its length. The steam-pipes are protected by wooden boxes, and are furnished with valves for regulating the supply of steam.

EARTHWORK.

To prepare a Table, T, of Level Cuttings, for every $\frac{1}{10}$ of a foot of height, or depth.



Let the fig represent the cutting; or if inverted, the filling, in which the horizontal lines are supposed to be $\frac{1}{10}$ foot apart. First calculate the area in square feet, of the layer *a b c o*, adjoining the roadway *a b*. Then find how many cubic yards that area gives in a distance of 100 feet. These cubic yards we will call Y, they form the first amount to be put into the Table T.

Next calculate the area in square feet of the triangle *a n o*. Multiply this area by 4. Find how many cubic yards this increased area gives in a distance of 100 feet. Or they will be found ready calculated below. We will call them *y*. This is all the preparation that is needed before commencing the table.

Exam.—Let the roadbed *a b* be 18 feet, and the side slopes 1½ to 1. Then for the area of *a b c o*: since the side slopes are 1½ to 1, and *s t* is .1 foot, *c o* must be 18.3 feet, and the mean length of *a b c o* must be 18.15 feet. Consequently, the area is 18.15 × .1 = 1.815 square feet, which, in a distance of 100 feet, gives 181.5 cubic feet, which is equal to $\frac{181.5}{27} = 6.7222$ cubic yards, or Y.

Next, as to the triangle *a n o*, its height *a n* being .1 foot, and its base *n o* .15 feet; its area $= \frac{.1 \times .15}{2} = \frac{.015}{2} = .0075$ square ft. This multiplied by 4, gives .03 square feet, which, in a distance of 100 feet, gives .03 × 100 = 3 cubic feet; which is equal to $\frac{.3}{27} = .1111$ cubic yard, or *y*.

Having thus found Y and *y*, proceed to make out the table in the manner following, which is so plain as to require no explanation. The work should be tested about every 5 feet, by calculating the area of the full depth arrived at; multiply it by 100, and divide the product by 27 for the cubic yards. The cubic yards thus found should agree with the table.

REMARK. **The foregoing tables of level cuttings may also be used for widths of roadway greater than those at the heads of the tables.** Thus, suppose we wish to use Table 1, for a roadbed *m n*, 16 ft wide, instead of *c b*, which is only 14 ft, and for which the table was calculated. It is only necessary first to find the vert dist *s a*, between these two roadbeds; and to add it *mentally* to each height *t s*, of the given embkt, when taking out from the

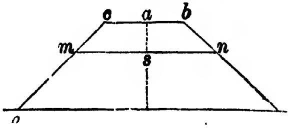

table the numbers of cub yds corresponding to the heights. By this means we obtain the contents of the embkt *c b o p*, for any required dist. Next, from these contents subtract that corresponding to the height *s a*, for the same dist. The remainder will plainly be the embkt *m n o p*.

In practice it will be sufficiently correct to take *s a* to the nearest tenth of a foot, which will save trouble in adding it mentally to the heights in the tables.

If the roadbed is narrower than the table, as, for instance, if *m n* be the width in the table, but we wish to find the contents for the width *c b*, then first find *s a*, and calculate the cubic yards in 100 feet length of *c b m n*. Then, in taking out the cubic yards from the table, first subtract *s a* mentally from each height; and to the cubic yards taken out for each 100 feet, opposite this *reduced* height, add the cubic yards in 100 feet of *c b m n*.

To avoid trouble with contractors about the measurement of rock cuts, stipulate in the contract, either that it shall conform with the theoretical cross section; or that an extra allowance of say about 2 feet of width of cut will be made, to cover the unavoidable irregularities of the sides.

Shrinkage of Embankment. Although earth, when first dug, and loosely thrown out, *swells* about ⅕ part, so that a cubic yard *in place* averages about 1⅕ or 1.2 cubic yards when dug: or 1 cubic yard dug is equal to ⅚, or to .8333 of a cubic yard in place; yet when made into embankment it gradually subsides, settles, or shrinks, into a less bulk than it occupied *before being dug*.

The following are approximate averages of the shrinkage; or, in other words, the earth measured in place in a cut, will, when made into embankment, occupy a bulk less than before by about the following proportions:

Gravel or sand	about	8 per ct;	or 1 in 12½ less.
Clay	"	10 per ct;	or 1 in 10 less.
Loam	"	12 per ct;	or 1 in 8⅓ less.
Loose vegetable surface soil	"	15 per ct;	or 1 in 6⅔ less.
Puddled clay	"	25 per ct;	or 1 in 4 less.

The writer thinks, from some trials of his own, that 1 cubic yard of any hard rock in place, will make from 1⅔ to 1¾ cubic yards of embankment; say on an average 1.7 cubic yards. Or that 1 cubic yard of rock embankment requires .5882 of a cubic yard in place. He found that a solid cubic yard when broken into fragments, made about as follows

	Cubic yards.	Of which there were Solid	Voids
In loose heap	1.9	52.6 per cent.	47.4 per cent
Carelessly piled	1.75	57 "	43 "
Carefully piled	1.6	63 "	37 "
Rubble, very carelessly scabbled	1.5	67 "	33 "
Rubble, somewhat carefully scabbled	1.25	80 "	20 "

COST OF EARTHWORK.

Art. 1. It is advisable to pay for this kind of work by the cubic yard of *excavation* only; instead of allowing separate prices for excavation and embankment. By this means we get rid of the difficulty of measurements, as well as the controversies and lawsuits which often attend the determination of the allowance to be made for the settlement or subsidence of the embankments.

It is, moreover, our opinion that justice to the contractor should lead to the **English practice of paying the laborers by the cubic yard,** instead of by the day. Experience fully proves that when laborers are scarce and wages high, men can scarcely be depended upon to do three fourths of the work which they readily accomplish when wages are low, and when fresh hands are waiting to be hired in case any are discharged. The contractor is thus placed at the mercy of his men. The writer has known the most satisfactory results to attend a system of task-work, accompanied by liberal premiums for all overwork. By this means the interests of the laborers are identified with that of the contractor; and every man takes care that the others shall do their fair share of the task.

Ellwood Morris, C E, of Philadelphia, was, we believe, the first person who properly investigated the elements of cost of earthwork, and reduced them to such a form as to enable us to calculate the total with a considerable degree of accuracy. He published his results in the Journal of the Franklin Institute in 1841. His paper forms the basis on which, with some variations, we shall consider the matter; and on which we shall extend it to wheelbarrows, as well as to carts. Throughout this paper we speak of a cubic yard considered only as solid in its place, or before it is loosened for removal. It is scarcely necessary to add that the various items can of course only be regarded as tolerably close approximations, or averages. As before stated, the men do less work when wages are high; and more when they are low. A great deal besides depends on the skill, observation, and energy of the contractor and his superintendents. It is no unusual thing to see two contractors working at the same prices, in precisely similar material, where one is making money, and the other losing it, from a want of tact in the proper distribution of his forces, keeping his roads in order, having his carts and barrows well filled, &c, &c. Uncommonly long spells of wet weather may seriously affect the cost of executing earthwork, by making it more difficult to loosen, load, or empty; besides keeping the roads in bad order for hauling.

The aggregate cost of excavating and removing earth is made up by the following items, namely:

1st. *Loosening the earth ready for the shovellers.*
2d. *Loading it by shovels into the carts or barrows.*
3d. *Hauling, or wheeling it away, including emptying and returning.*
4th. *Spreading it out into successive layers on the embankment.*
5th. *Keeping the hauling-road for carts, or the plank gangways for barrows, in good order.*
6th. *Wear, sharpening, depreciation, and interest on cost of tools.*
7th. *Superintendence, and water-carriers.*
8th. *Profit to the contractor.*

We will consider these items a little in detail, basing our calculations on the assumption that common labor costs \$1 per day, of 10 working hours. The results in our tables must therefore be increased or diminished in about the same proportion as common labor costs more or less than this.

Art. 2. Loosening the earth ready for the shovellers. This is generally done either by ploughs or by picks; more cheaply by the first. A plough with two horses, and two men to manage them, at \$1 per day for labor, 75 cents per day for each horse and 37 cents per day for plough, including harness, wear repairs &c or a total of \$3 87, will loosen, of strong heavy soils, from 200 to 300 cubic yards a day, at from 1.93 to 1.29 cents per yard; or of ordinary loam, from 400 to 600 cubic yards a day, at from .97 to .64 of a cent per yard. Therefore, as an ordinary average, we may assume the actual cost to the contractor for loosening by the plough, as follows: strong heavy soils, 1.6 cents; common loam, .8 cent; light sandy soils, .4 cent. Very stiff pure clay, or obstinate cemented gravel, may be set down at 2 5 cents; they require three or four horses.

By the pick, a fair day's work is about 14 yards of stiff pure clay, or of cemented gravel; 25 yards of strong heavy soils; 40 yards of common loam, 60 yards of light sandy soils—all measured in place, which, at \$1 per day for labor, gives, for stiff clay, 7 cents; heavy soils, 4 cents; loam, 2 5 cents; light sandy soil, 1 666 cents. Pure sand requires but very little labor for loosening; .5 of a cent will cover it.

Art. 3. Shovelling the loosened earth into carts. The amount shovelled per day depends partly upon the weight of the material, but more upon so proportioning the number of pickers and of carts to that of shovellers, as not to keep the latter waiting for either material or carts. In fairly regulated gangs, the shovellers into carts are not actually engaged in shovelling for more than six-tenths of their time, thus being unoccupied but four-tenths of it; while, under bad management, they lose considerably more than one-half of it. A shoveller can readily load into a cart one-third of a cubic yard measured in place (and which is an average working cart-load), of sandy soil, in five minutes; of loam, in six minutes; and of any of the heavy soils, in seven minutes. This would give for a day of 10 working hours, 120 loads, or 40 cubic yards of light sandy soil; 100 loads, or 33⅓ cubic yards of loam; or 86 loads, or 28.7 yards of the heavy soils. But from these amounts we must deduct four tenths for time necessarily lost; thus reducing the actual working quantities to 24 yards of light sandy soil, 20 yards of loam, 17.2 yards of the heavy soils. When the shovellers do less than this, there is some mismanagement.

Assuming these as fair quantities, then, at \$1 per day for labor, the actual cost to the contractor for shovelling per cubic yard measured in place, will be, for sandy soils, 4.167 cents; loam, 5 cents; heavy soils, clays, &c, 5.81 cents.

In practice, the carts are not usually loaded to any less extent with the heavier soils than with the lighter ones. Nor, indeed, is there any necessity for so doing, inasmuch as the difference of weight of a cart and one-third of a cubic yard of the various soils is too slight to need any attention; especially when the cart-road is kept in good order, as it will be by any contractor who understands his

own interest. Neither is it necessary to modify the load on account of any *slight inclinations* which may occur in the grading of roads. An earth cart weighs by itself about ½ a ton.

Art. 4. Hauling away the earth; dumping, or emptying; and returning to reload. The average speed of horses in hauling is about 2¼ miles per hour, or 200 feet per minute, which is equal to 100 feet of trip each way; or to 100 feet of *lead*, as the distance to which *the earth is hauled* is technically called * Besides this, there is a loss of about four minutes in every trip, whether long or short, in waiting to load, dumping, turning, &c. Hence, every trip will occupy as many minutes as there are lengths of 100 feet each in the lead; and four minutes besides. Therefore, to find the number of trips per day over any given average lead, we divide the number of minutes in a working day by the sum of 4 added to the number of 100 feet lengths contained in the distance to which the earth has to be removed, that is,

$$\frac{\textit{The number (600) of minutes in a working day}}{4+\textit{the number of 100 feet lengths in the lead}} = \textit{the number of trips, or loads removed per day, per cart.}$$

And since ⅓ of a cubic yard measured before being loosened, makes an average cart-load, the number of loads, divided by 3, will give the number of cubic yards removed per day by each cart; and the cubic yards divided into the total expense of a cart per day, will give the cost per cubic yard for hauling.

REMARK. When removing loose *rock*, which requires more time for loading, say,

$$\frac{\textit{No. of minutes (600) in a working day}}{6+\textit{No. of 100-feet lengths of lead}} = \textit{No. of loads removed, per day, per cart.}$$

In leads of ordinary length one driver can attend to 4 carts; which, at $1 per day, is 25 cents per cart. When labor is $1 per day, the expense of a horse is usually about 75 cents, and that of the cart, including harness, tar, repairs, &c, 25 cents, making the total daily cost per cart $1.25. The expense of the horse is the same on Sundays and on rainy days, as when at work; and this consideration is included in the 75 cents. Some contractors employ a greater number of drivers, who also help to load the carts, so that the expense is about the same in either case

EXAMPLE How many cubic yards of loam, measured in the cut, can be hauled by a horse and cart in a day of 10 working hours, (600 minutes,) the lead, or length of haul of earth being 1000 feet, (or 10 lengths of 100 feet,) and what will be the expense to the contractor for hauling, per cubic yard, assuming the total cost of cart, horse, and driver, at $1.25?

$$\textit{Here,}\ \frac{600\ \textit{minutes}}{4+10\ \textit{lengths of 100 feet,}} = \frac{600}{14} = 43\ \textit{loads.} \quad \textit{And}\ \frac{43\ \textit{loads}}{3} = 14.3\ \textit{cubic yards.}$$

$$\textit{And}\ \frac{125\ \textit{cents}}{14.3\ \textit{cub yds}} = 8.74\ \textit{cents per cubic yard.}$$

In this manner the 2d and 3d columns of the following tables have been calculated.

Art. 5. Spreading, or levelling off the earth into regular thin layers on the embankment. A bankman will spread from 50 to 100 cubic yards of either common loam, or any of the heavier soils, clays, &c, depending on their dryness This, at $1 per day, is 1 to 2 cents per cubic yard; and we may assume 1½ cents as a fair average for such soils; while 1 cent will suffice for light sandy soils.

This expense for spreading is saved when the earth is either dumped over the end of the embankment, or is wasted; still, about ¼ cent per yard should be allowed in either case for keeping the dumping-places clear and in order.

Art. 6. Keeping the cart-road in good order for hauling. No ruts or puddles should be allowed to remain unfilled; rain should at once be led off by shallow ditches; and the road be carefully kept in good order; otherwise the labor of the horses, and the wear of carts, will be *very greatly* increased. It is usual to allow so much per cubic yard for road repairs; but we suggest so much per cubic yard, per 100 feet of lead; say $\frac{1}{10}$ of a cent.

Art. 7. Wear, sharpening, and depreciation of picks and shovels. Experience shows that about ¼ of a cent per cubic yard will cover this item.

Superintendence and water-carriers. These expenses will vary with local circumstances; but we agree with Mr. Morris, that 1½ cents per cubic yard will, under ordinary circumstances, cover both of them. An allowance of about ½ cent may in justice be added for extra trouble in digging the side-ditches; levelling off the bottom of the cut to grade, and general trimming up. In very light cuttings this may be increased to ½ cent per cubic yard

At ½ cent, all the items in this article amount to 2 cents per cubic yard of cut.

Art. 8. Profit to the contractor. This may generally be set down at from 6 to 15 per cent, according to the magnitude of the work, the risks incurred, and various incidental circumstances. Out of this item the contractor generally has to pay clerks, storekeepers, and other agents, as well as the expenses of shanties, &c; although these are in most cases repaid by the profits of the stores; and by the rates of boarding and lodging paid to the contractors by the laborers.

Art. 9. A knowledge of the foregoing items enables us to calculate with tolerable accuracy the cost of removing earth. For example, let it be required to ascertain the cost per cubic yard of excavating common loam, measured in place; and of removing it into embankment, with an average haul or lead of 1000 feet; the wages of laborers being $1 per day of 10 working hours; a horse 75 cts a day; and a cart 25 cts. One driver to four carts

---

* When an entire cut is made into an embankment, the **mean haul** is the dist between centers of gravity of the cut and embkt.

		Cents.
Here we have cost of loosening, say by pick,	*Art* 2, *per cubic yard, say,*	2 50
Loading into carts,	*Art* 3, " "	5 00
Hauling 1000 *feet, as calculated previously in example, Art.* 4, "		8 74
Spreading into layers,	*Art* 5, "	1 50
Keeping cart-road in repair,	*Art* 6, 10 *lengths of* 100 *ft,*	1 00
Various items in	*Art* 7,	2 00
	Total cost to contractor,	20 74
	Add contractor's profit, say 10 *per cent,*	2 074
	Total cost per cubic yard to the company,	22.814

It is easy to construct a table like the following, of costs per cubic yard, for different lengths of lead. Columns 2 and 3 are first obtained by the Rule in Article 4, then to each amount in column 3 is added the *variable* quantity of $\frac{1}{10}$ of a cent for every 100 feet length of lead, for keeping the road in order, and the *constant* quantity (for any given kind of soil) composed of the prices per cubic yard, for loosening, loading, spreading, or wasting, &c, either taken from the preceding articles, or modified to suit particular circumstances. In this manner the tables have been prepared.

By Carts. Labor $1 per day, of 10 working hours.

Art. 10. By wheelbarrows. The cost by barrows may be estimated in the same manner as by carts See Articles 1, &c. Men in wheeling move at about the same average rate as horses do in hauling, that is, 2½ miles an hour, or 200 feet per minute, or . minute per every 100-feet length of lead. The time occupied in loading, emptying, &c (when, as is usual, the wheeler loads his own barrow,) is about 1 25 minutes, without regard to length of lead besides which, the time lost in occasional short rests, in adjusting the wheeling-plank, and in other incidental causes, amounts to about $\frac{1}{10}$ part of his whole time; so that we must in practice consider him as actually working but 9 hours out of his 10 working ones. Therefore

$$\frac{\textit{The number of minutes in a working day} \times .9}{1.25 + \textit{the number of 100-feet lengths of lead}} = \textit{the number of trips or of loads removed per day per barrow.}$$

See Remark, next page.
The number of loads divided by 14 will give the number of cub yards, since a cub yard, measured in place, averages about 14 loads And the cost of a wheeler and barrow per day, (say $1 per man, and 5 cents per barrow,) divided by the number of cub yards, will give the cost per yard for loading wheeling, and emptying.

Ex. How many cubic yards of common loam, measured in place, will one man load, wheel, and empty, per day of 10 working hours, (or 600 minutes;) the lead, or distance to which the earth is removed being 1000 feet, (or 10 lengths of 100 feet;) and what will be the expense per yard, supposing the laborer and barrow to cost \$1.05 per day?

$$\textit{Here, } \frac{600 \textit{ minutes} \times .9}{1.25 + 10 \textit{ lengths}} = \frac{540}{11.25} = 48 \textit{ trips, or loads per day.}$$

$$\textit{And } \frac{48}{14} = 3.43 \textit{ cub yds per day.} \quad \textit{And } \frac{105 \textit{ cents}}{3.43 \textit{ cub yds}} = 30.6 \textit{ cents}$$

per cub yard for loading, wheeling away, emptying, and returning. This would be increased almost inappreciably by the cost of the shovel, which, in the following tables, however, is included in the cost of tools.

Rem. For *rock*, which requires more time for loading, say

$$\frac{\textit{No of minutes in a working day} \times .9}{1.6 + \textit{No of 100-feet lengths of lead}} = \textit{No of loads removed per day, per barrow.}$$

Art. 11. The following tables are calculated as in the case of carts, by first finding columns 2 and 3 by means of the Rule in Art 10, and then adding to each sum in column 3, the variable quantity of .1 of a cent per cubic yard per 100 feet of lead for keeping the wheeling-planks in order, and the prices of loosening, spreading, superintendence, water-carrying, &c, per cubic yard, as given in the preceding Articles 2, 5 and 7.

By Wheelbarrows. Labor \$1 per day, of 10 working hours.

Art. 12. By wheeled scrapers and drag scrapers. The body of the wheeled scraper is a box of smooth sheet-steel about 3½ ft square by 15 ins deep, containing about ½ cubic yard of earth when "even full." The box is open in front (in some machines it is closed by an "end gate" when full), and can be raised and lowered, and revolved on a horizontal axis. To fill the box, it is lowered into, and held down in, the earth, while the team draws the machine forward. When full, it is raised to about a foot above ground; and, on reaching the dump, is unloaded by being overturned on its axis. All the movements of the box are made by means of levers, and without stopping the team, which thus travels constantly. The wheels have broad tires, to prevent them from cutting into the ground.

In the *drag* scraper the box, owing to the greater resistance to traction, is made much smaller. It contains about .15 to .25 cubic yard in place, and is always open in front. The operation of the drag scraper is similar to that of the wheeled scraper, except that the box, when filled, rests upon the ground and is dragged over it by the team.

Each scraper ("wheeled" or "drag") requires the constant use of a team of two horses with a driver. Besides, a number of men, depending on the shortness of the lead and the number of scrapers, are required in the pit and at the dump to load the scrapers (by holding the box down into the earth) and unload them (by tipping the box). Except in sand, or in very soft soil, it is economical to use a plow before scraping.

The severest work for the team is the filling of the box; and this occurs oftenest where the lead is shortest. Hence smaller scrapers are used on short than on long hauls. We base our calculations on the following loads:

For drag scrapers (used only on short hauls)	.2	cubic yard
For wheeled scrapers		
lead less than 100 feet	.33	"
" 100 to 300 feet	.4	"
" 400 to 500 feet	.5	"
" over 500 feet	.6	"

The daily expense per scraper, for driver's wages and the use of a 2-horse team, is about \$3.50 For loads of 400 feet and over, we add 50 cts per day for use of "snatch team" to help load the larger scrapers then used. One snatch team generally serves a number of scrapers.

Owing to the fact that the teams are constantly in motion without rest, they travel somewhat more slowly than with carts We take 150 ft per minute (or 75 ft of *lead* per minute) as an average.

In loading and unloading, the teams not only go out of their way in order to turn around, but travel more slowly than when simply hauling. To cover this we make an addition of 100 ft to each length of lead, whether long or short, for wheeled scrapers and for drag scrapers.

We add 1 cent per cubic yard for the cost of loading and dumping the scrapers; and estimate the approximate cost of the other items as follows·

Repairs of cart-road $\frac{1}{10}$ ct per cub yd in place for each 100 ft of lead

	Light Soils cts per cub yd in place	Heavy Soils cts per cub yd in place
Loosening		
by pick	*	5.
by plow	*	2.
Spreading	1.	1.5
Superintendence, wear and tear etc.	1	1.

We repeat that our figures are to be regarded merely as tolerable approximations, and subject to great variations according to skill of contractor and superintendent, strength of teams, character of material moved, state of weather etc etc.

$$\text{No. of trips per day per scraper} = \frac{\text{No. (600) of mins in a working day}}{\text{No. of 75 ft lengths in (lead + 100 ft)}}$$

$$\text{No. of cub yds in place moved per day by each scraper} = \text{No. of trips per day per scraper} \times \text{No. of cub yds in place, per scraper per trip}$$

$$\text{Cost per cub yd in place, for loading, hauling, dumping and returning} = \frac{\text{Daily expense of one scraper}}{\text{No. of cub yds in place, moved per day by each scraper}} + \text{1 ct for loading and dumping}$$

$$\text{Total cost per cubic yard in place exclusive of contractor's profit} = \text{Cost per cub yd in place, for loading, hauling, dumping, and returning} + \text{.1 ct per cub yd in place for each 100 ft of lead, for repairs of road} + \text{Cost, per cub yd in place, of loosening, spreading or wasting, and superintendence \&c.}$$

By Wheeled Scrapers. Labor \$1 per day of 10 working hours.

Art. 13. By cars and locomotive, on level track. We have based our calculations upon the following assumptions: Trains of 10 cars, each car containing $1\frac{1}{2}$ cubic yards of earth measured in place. Average speed of trains, including starting and stopping, but not standing, 10 miles per hour, = 5 miles of *lead* per hour. Labor $1 per day of 10 working hours. Loosening, loading (by shovelers), spreading, wear &c of tools, superintendence, &c, the same as with carts, Arts 2, 3, 5, and 7. Loss of time in each trip for loading, unloading, &c, 9 minutes, = 0.15 hour. Therefore

$$\left.\begin{array}{l}\text{Number of trips per}\\ \text{day, per train}\end{array}\right\} = \frac{\text{The number (10) of hours in a working day}}{.15 + \text{the number of 5-mile lengths in the lead}}$$

$$\left.\begin{array}{l}\text{Number of cubic}\\ \text{yards in place, per}\\ \text{day per train}\end{array}\right\} = \begin{array}{l}\text{Number of}\\ \text{trips per day}\\ \text{per train}\end{array} \times \begin{array}{l}\text{Number (10)}\\ \text{of cars in a}\\ \text{train}\end{array} \times \begin{array}{l}\text{Number (1.5) of cubic}\\ \text{yards in place in each}\\ \text{car}\end{array}$$

$$\left.\begin{array}{l}\text{Cost per cubic yard, in place,}\\ \text{for hauling, dumping, and}\\ \text{returning}\end{array}\right\} = \frac{\text{One day's train expenses + 1 day's cost of track}}{\text{Number of cubic yards in place per day per train}}$$

One day's train expenses:

Cost of 10 cars @ $100	$1000		
" locomotive	3000		
		$4000	
One day's interest at 6 per cent, on cost of train			$0.67
Wages of engine driver (who fires his own engine)			2.00
" foreman at dump			2.00
" 3 men at dump at $1			3.00
Fuel			2.00
Water			1.00
Repairs of locomotive and cars			2.33
Total daily expense of one train			**$13.00**
Depreciation (life of rolling stock taken as 10 years) say $100 per annum per $1000, = $400 " " " train, = $ 4 " day (assuming 100 working days per year)			4.00
Daily expense and depreciation, one train			$17.00

Taking cost of track, laid, at $2500 per mile, and its life at 5 years, **the daily expense of track,** for interest, depreciation, handling and repairs, may be taken at $6.00 for each mile of lead.

Therefore

$$\left.\begin{array}{l}\text{Cost per cubic yard in place,}\\\text{for hauling, dumping, and}\\\text{returning}\end{array}\right\} = \frac{\$17 + (\$6 \text{ for each mile of lead})}{\begin{array}{l}\text{Number of}\\\text{trips per day}\\\text{per train}\end{array} \times \begin{array}{l}\text{Number (10)}\\\text{of cars in a}\\\text{train}\end{array} \times \begin{array}{l}\text{Number (1.5) of}\\\text{cubic yards}\\\text{each car}\end{array}}$$

$$\left.\begin{array}{l}\text{Total cost per cubic}\\\text{yard in place, ex-}\\\text{clusive of contrac-}\\\text{tor's profit}\end{array}\right\} = \begin{array}{l}\text{Cost per cub yd in}\\\text{place for hauling,}\\\text{dumping, and re-}\\\text{turning}\end{array} + \begin{array}{l}\text{Cost per cubic yard, in place, for}\\\text{loosening, loading, spreading or}\\\text{wasting, and superintendence, \&c}\\\text{(Arts 2, 3, 5, and 7.)}\end{array}$$

By Cars and Locomotive. Labor $1 per day of 10 working hours.

Art. 14. Removing rock excavation by wheelbarrows. A cubic yard of hard rock, *in place*, or before being blasted, will weigh about 1.8 tons, if sandstone or conglomerate, (150 lbs per cubic foot;) or 2 tons if good compact granite, gneiss, limestone, or marble, (168 lbs per cubic foot.) So that, near enough for practice in the case before us, we may assume the weight of any of them to be about 1.9 tons, or 4256 lbs per cubic yard, in place; or 158 lbs per cubic foot.

Now, a solid **cubic yard, when broken up** by blasting for removal by wheelbarrows or carts, will occupy a space of about 1.8, or $1\frac{4}{5}$ cubic yards; whereas average earth, when loosened, swells to but about 1.2, or $1\frac{1}{5}$ of its original bulk in place; although, after being made into embankment, it eventually shrinks into less than its original bulk. In estimating for earth, it is assumed that $\frac{1}{14}$ cubic yard, in place, is a fair load for a wheelbarrow. Such a cubic yard will weigh on an average 2430 lbs, or 1.09 tons; therefore, $\frac{2430}{14} = 174$ lbs, is the weight of a barrow-load, of 2.31 cubic feet of loose earth. Assuming that a barrow of loose rock should weigh about the same as one of earth, we may take it at $\frac{1}{24}$ of a cubic yard; which gives $\frac{4256}{24} = 177$ lbs per load of loose rock, occupying 2 cubic feet of space.

In the following table, columns 2 and 3 are prepared on the same principle as for earth, as directed in Article 10. Column 4 is made up by adding to each amount in column 3, .2 of a cent for each 100 feet length of lead, for keeping the wheeling-planks in order; and 45 cents per cubic yard, in place, as the actual cost for loosening, including tools, drilling, powder, &c; as well as moderate drainage, and every ordinary contingency not embraced in column 3. Contractor's profits, of course, are not here included.

Ample experience shows that when labor is at $1 per day, the foregoing 45 cents per cubic yard, in place, is a sufficiently liberal allowance for loosening hard rock under all ordinary circumstances. In practice it will generally range between 30 and 60 cents, depending on the position of the strata, hardness, toughness, water, and other considerations. Soft shales, and other allied rocks, may frequently be loosened by pick and plough, as low as 15 to 20 cents; while, on the other hand, shallow cuttings of very tough rock, with an unfavorable position of strata, especially in the bottoms of excavations, may cost $1, or even considerably more. These, however, are exceptional cases, of comparatively rare occurrence. The quarrying of average hard rock requires about ¼ to ½ lb of powder per cubic yard, in place; but the nature of the rock, the position of the strata, &c. may increase it to ½ lb, or more. Soft rock frequently requires more powder than hard. A good churn-driller will drill 8 to 10 feet in depth, of holes about 2½ feet deep, and 2 inches diameter, per day, in average hard rock, at from 12 to 18 cents per foot. Drillers receive higher wages than common laborers.

Hard Rock, by Wheelbarrows.

Labor $1 per day, of 10 working hours.

Length of Lead, or distance to which the rock is wheeled.	Number of cubic yards, in place, wheeled per day by each barrow.	Cost per cubic yard, in place, for loading, wheeling, and emptying. Art. 15. Removing rock excavation by carts. A cart-load of rock may be taken at $\frac{1}{5}$ of a cubic yard, in place. This will weigh, on an average, 851 lbs; or but 41 lbs more than a cart-load of average soil. Since the cart itself will weigh about ½ a ton, the total loads are very nearly equal in both cases. Columns 2 and 3 of the following table are prepared on the same principle as for earth, as directed in Art. 4. Column 4 is made up by adding to each amount in column 3, the following items: For blasting, (and for everything except those in column 3; loading, and repairs of cart-road,) 45 cents per cubic yard, in place; for loading, 8 cents, per cubic yard, in place; and for repairs of road, .2, or $\frac{1}{5}$ of a cent for each 100-feet length of lead. Contractor's profit not included.

Hard Rock, by Carts.

Labor $1 per day, of 10 working hours.

Length of lead, or distance to which the rock is hauled.	Number of cubic yards, in place, hauled per day, by each cart.	Cost per cubic yard, in place, for hauling, and emptying. "**Loose rock**" will cost about 30 cts per yd less; and even *solid* rock will *average* about 10 cts less than the tables.

Art. 16. Removing rock excavation by cars and locomotive, on level track; each car holding 1 cu yd of rock, instead of 1.5 cu yds of earth as in Art. 13. This makes hauling cost, for a given lead, 50 per cent greater than for earth. Loosening and loading costs are as in Art. 15; other assumptions as in Art. 13.

Hard Rock, by Cars and Locomotive.

Labor $1 per day of 10 working hours.

TUNNELS.

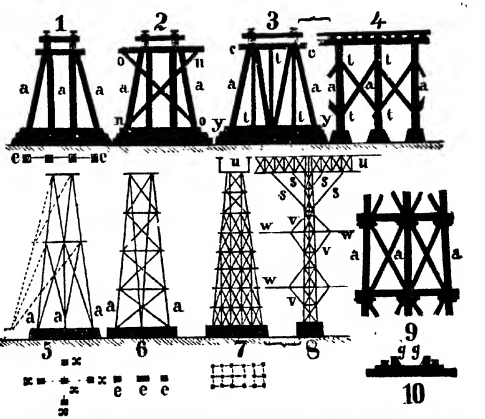
Tunnels for railroads should, if possible, be straight, especially when there is but a single track; inasmuch as collisions or other accidents in a tunnel would be peculiarly disastrous. A tunnel will rarely be expedient before the depth of cutting exceeds 60 feet. Firm rock of moderate hardness, and of a durable nature, is **the most favorable material** for a tunnel; especially if free from springs, and lying in horizontal strata. In soft rock, or in shales (even if hard and firm at first), or in earth, a lining of hard brick or masonry in cement, is necessary. A tunnel should have a **grade or inclination** in one direction, for ease of future drainage and ventilation. No special arrangement is essential for **ventilation** either during construction, or after, if the length does not exceed about 1000 feet; but beyond that, generally during construction either shafts are resorted to, or means provided for forcing air into the tunnel through pipes from its ends. But after the work is finished, except under peculiar circumstances, nothing of the kind is necessary. Shafts often draw air downwards; and frequently, even when aided by a steep, uniform grade, do not secure ventilation. The Mont Cenis tunnel under the Alps, completed in 1871, is 7½ miles long, and has no shafts, although it grades up from each end, which is the most unfavorable of all conditions for ventilation without shafts. It was made so for facilitating drainage. Its ventilation is maintained by air forced in from the ends. The Hoosac tunnel, Mass, 4¾ miles long, has shafts; one of them 1030 feet deep; but they were for expediting the work. **Shafts generally cost** from 1½ to 3 times as much per cubic yard as the main tunnel, owing to the greater difficulty of excavating and removing the material, and getting rid of the water, all of which must be done by hoisting. When through earth, they must be lined as well as the tunnel and the lining must usually be an under-pinning process. Or the lining may first be built *over* the intended shaft, and then sunk by undermining it gradually. Their sectional area commonly varies from about 40 to 100 square feet. They have the great advantage of expediting the work by increasing the number of points at which it can be carried on; but if placed too close together, their cost more than compensates for this. The air in some tunnels, while being constructed, is much more foul than in others; so that after the work has been commenced, shafts with forced air may be expedient where they were not anticipated. In excavating the tunnel itself, a **heading** or passage-way, 5 or 8 feet high, and 3 to 12 feet wide, is driven and maintained a short distance (10 to 100 feet, or more, according to the firmness of the material) in advance of the main work. In rock, the heading is just below the top of the tunnel, so that the men can conveniently drill holes in its floor for blasting; but in earth, the heading is driven along the bottom of the tunnel, that being the most convenient for enlarging the aperture to the full tunnel size, by undermining the earth, and letting it fall. In earth, the top and sides of the heading, as well as of the tunnel, must be carefully prevented from caving in before the lining is built; and this is done by means of rows of vertical rough timber props, and horizontal caps or overhead pieces, between which and the earth rough boards are placed to form temporary supporting sides and ceiling to the excavation. The props and caps are placed first; and the boards are then driven in between them and the earthen sides of the excavation. These are gradually removed as the lining is carried forward **The lining,** when of brick, is usually from 2 to 3 bricks thick (17 to 26 inches) at bottom, and from 1½ to 2½ bricks thick at top; and when of rough rubble in cement, about half again as thick. It is important that the bricks or stone should be of excellent hard quality, and laid in good cement. The bricks should be moulded to the shape of the arch. As the lining is finished in short lengths, and before the centers are removed, any **cavities or voids** between it and the earth should be carefully and compactly filled up. Even in rock, if much fissured, or if not of durable character, as common shale, lining is necessary. **The cross-section** of a single-track railroad tunnel, in the clear of everything, and for cars of 11 feet extreme width, should not be *less* than about 15 feet wide, by 18 feet high; nor a double-track one, less than 27 feet wide, by 24 feet high; unless in the last case the material is firm rock, in which a high arch is not necessary for lining. The roof may then be much flatter, so that a height of 20 feet may answer. With cars of 10 feet extreme width, the width of the tunnel may be reduced to 25 feet; or with 9 feet cars, to 23 feet. Many have been made 22 feet. The Mont Cenis is 26 feet wide, by 25 high. **The rate of daily progress** from *each* face of a tunnel varies from 18 inches to 9 feet of length per 24 hours, with three relays of workmen. On the Mont Cenis the ex-

tremes were about 4 to 9 feet daily for a whole year, from each face. Drills worked by compressed air were employed in the headings, which were 12 feet wide by 8 feet high. Ordinarily, from $1\frac{1}{2}$ to 3 feet may be taken as averages. The difference of rate of progress between a single and a double track tunnel is not so great as might be supposed; inasmuch as a larger force can be employed on the wider one. If the tunnel is in earth, the construction of the lining about makes up for the slower excavation of one in rock. In rock, with labor at $1 per day, **the cost** will usually vary with the character of the rock, from $2 to $5 per cubic yard for the main tunnel; and from $3 to $10 for the heading; while shafts will average about 50 per cent. more than heading. The cost of a single-track tunnel, when common labor is $1 per day, will generally range between $30 and $75 per foot of length. Tunnel work, however, is liable to serious contingencies which cannot be foreseen. Since the sides and roof are rough as blasted. the width and height should each be estimated to the contractor as about 18 inches or 2 feet greater than the established *clear* ones. At any rate, the mode of measurement should be clearly stated in the specifications for the work. When a tunnel is made with a uniform grade, the work generally progresses in a more satisfactory manner from the lower end, because the descent favors the drainage of the spring water that is usually met with; whereas, at the upper end, it must be removed by pumps or by bailing. The upper end has, however, the advantage of sooner getting rid of the smoke in blasting. Before commencing a tunnel, or even deciding upon one, **trial shafts** should be sunk to ascertain the nature of the material. In long ones, the greatest care and accuracy are necessary for preserving the line of direction, so that the work from both ends shall meet properly at the center.

In the heading of the Vosburg (Pa) tunnel of the Lehigh Valley R R, built 1884, cross-section $7\frac{1}{2}$ feet × 26 feet, the **average progress** per working day of 24 hours with two shifts of 12 hours each, was as follows; by hand drilling 2.8 feet and 2.4 feet respectively from each end; by machine drills (two rival drills in competition) 5.6 feet and 7.8 feet. The material was hard gray sandstone. For the whole tunnel the rate was about 2 feet per day.

For further information respecting tunnels, the reader is referred to Mr. H S. Drinker's very full treatise on the subject, published by the Messrs Wiley.

TRESTLES.



FIGS 1, 2. 3, 5, 6, 7, are **elevations of trestles**; taken across the track or roadway. We may consider Fig 1 as adapted to a height of about 10 to 20 ft; Figs 2

and 8, to heights from 20 to 30 ft; Fig 5, from 30 to 40 ft, Fig 6, from 40 to 60 ft, as rough approximations merely. A single framework, such as that shown in each of these six figures, is called a "bent." These bents of course admit of many modifications. They are usually supported by bases of masonry, as in the figures. These preserve the lower timbers from contact with the earth, which would hasten their decay. It is advisable to make these bases high enough to prevent injury from cattle, or passing vehicles, &c. Up to heights of about 40 or 50 ft, a single row of posts or uprights, *a*, *a*, *a*, Figs 1 to 9, as shown at *e e* under Figs 1 and 6, will answer. But as the height becomes greater, more posts should be introduced, as shown at *x x* under Fig 5; or two entire rows of them; or three rows, as under Fig 7; and as also in Fig 8, which is an end view of Fig 7. Figs 7 and 8 bear much resemblance to the trestles 190 ft high, with masonry bases 30 ft high (S. Seymour, C. E.), which carried the Erie Rway (now the N Y, Lake Erie & West'n R R) over the **Genesee River at Portage, N Y.** There each bent had 21 posts 14 ins square, at its base, and 15 posts of 12 × 12, at its top. The other timbers were 6 × 12; many of them were in pairs, embracing the posts. This single-track viaduct was begun July 1, 1851, and completed Aug. 14, 1852. It contained 1,602,000 ft (B M) of timber, and 108,862 lbs of iron. In the foundations were 9200 cub yds of masonry. The entire cost was about $140,000. It was burned down in 1875, and was replaced, in less than 3 mos, with a single-track **viaduct of wrought-iron trestles,** containing, in all, 1,340,000 lbs of iron, and 130,600 ft (B M) of timber; and costing, complete, above the masonry, about $95,000. Frequently the posts of trestles are in pairs; and the other timbers pass between; all bolted together.

In Fig 4, the posts *a*, *a*, *a*, are end views of three trestles or bents, such as Fig 3; and *t t* are diag braces extending from trestle to trestle: the two outer ones inclining in one direction; and the central one crossing them. These may be placed either intermediate of the posts, as in Fig 3; with the heads of the two outer ones confined to the cap *c c* of one trestle; and their feet to the sill *y y* of the next one, or they may all be spiked or bolted to the posts themselves, as in Fig 4. The last is the best, as it serves also directly to stiffen the posts: as do also the braces *o o*, *n n*, Fig 2. Such bracing is too frequently omitted. During the passage of trains, the backward pressure of the steam, exerted through the driving wheels against the track, produces a serious strain lengthwise of the road, and tending to upset the trestles; and the sudden application of brakes to a moving train, produces a similar strain in the opposite direction. These strains become more dangerous as the ht increases. Hence the need for such braces. Usually the outer **posts may lean** 1.5 to 2.5 ins to a ft.

The posts should not be less than about 12 ins square, except in quite low trestles; and even then not less than about 10 × 10 The diag bracing may generally be about as wide as the posts; and half as thick. The dist apart of the bents, when the road way is supported by simple longitudinal beams, should not exceed 10 or 12 ft, for railroads. But if these beams receive support from braces beneath, like *s s*, Fig 8; or from iron truss rods, the dist may be extended to 15 or 20 or more ft. But when the trestles become very high, and contain a great deal of timber, it becomes cheaper to place them farther apart, say 30 to 60 ft; and to carry the railway upon regular framed trusses, as at *u u*, Figs 7 and 8; as in a bridge with stone piers. In the Genesee viaduct, the trestles were 50 ft apart, center to center

When such a trestle as Fig 8 becomes very narrow in proportion to its height, we may add to its stability by introducing beams *w*, extending from trestle to trestle and still further by inserting diag braces *v v*, as in the old Genesee viaduct.

As far as practicable, arrange the pieces so that any one may be removed if it becomes decayed; and another put in its place.

On curves, additional strength should be given on the convex side; as suggested by the dotted lines in Fig 5. On very high trestles especially (as well as on bridges), wheel-guards, *g g*, Fig 10, either inside or outside of the rails, should never be omitted.

In marshy ground, piles may be driven to support the trestles; or may be left so far above ground, as themselves to constitute the posts. Such trestles may often be used advantageously, even when to be afterward filled in by embkt. They then sustain the rails at their proper level until the embkt has reached its final settlement.

They are generally used to avoid the expense of embkt; especially when earth can only be obtained from a great dist. Even when earth and timber are equally convenient, they will rarely much exceed about half the cost of embkt; even when but about 30 ft high; but owing to their liability to decay, they should be resorted to only in case of necessity; or as a temporary expedient.

Bridges. See Trusses, p 689, etc, and Stone Bridges, (Arches), p 613, etc.

ROLLING STOCK

GENERAL

1. General features, and details common to both locomotivs and cars. Under this head we aim to give only such general information as may be serviceable to *civil* engineers, who are concernd chiefly with the *fixt* plant of railways.

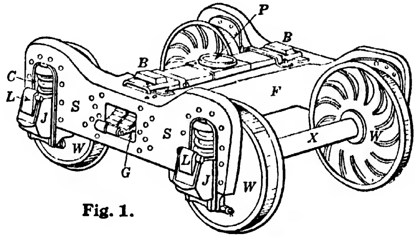


Fig. 1.

2. Trucks. A truck, Fig 1, is a frame into which the journal boxes, *C*, of the axles are fitted, and which supports the car body. In the U. S., a truck is seldom used singly, supporting the vehicle by direct and rigid attachment; but is almost invariably connected with the car or locomotiv by means of a pivot, *P*, which enables it to adapt itself to changes in direction of track. Trucks, especially the side pieces, *SS*, were formerly made up of heavy steel flat bars, forming a simple truss, and many are still in use. On newer equipment, "pressed" steel side frames are largely used (which act as girders) and also cast steel side frames, being patternd after the older flat bar trussed frames.

3. The pivot, *P*, is at the center of the truck, except in special types of locomotiv trucks, and in some electric car trucks where only one motor is used on one pair of wheels and where the pivot is placed more nearly over the driving wheels, to give better "adhesion."

4. Side-bearings. The load is usually carried by bearings at the pivot, and only those loads due to the side swing of the car are taken by side-bearings, *B, B*; but in some types, now in use, all the loads are carried by the side bearings, while the pivot takes none.

5. Springs. Elliptic, flat, or coild springs are provided between the main truck frame, *F*, and the bolster, *B P B*, which carries the pivot bearing. For passenger service, at least, a coild spring is placed also between each journal box and the truck frame. Coil springs are built in nests of two or more, one within the other, and these nests are also used in pairs, side by side, or in groups of four or more, especially where used between the truck frame and the car body. Semi-elliptical springs are usual on locomotivs.

6. Journal Boxes. The journals turn in the journal boxes. The bearing is of course upon the upper side of the journal. Each box is large enough to contain a supply of oild waste for lubrication. A lid, *L*, permits access, and keeps out much dirt. Roller bearings have been used in electric traction work.

7. Journals. Under cars, and in the axles of two-wheeld locomotiv trailer trucks, the journals are at the ends of the axles, outside the wheels; in loco driving wheel axles, between the driving wheels. Journals range from 3¾ to 6 ins in diam, and from 7 to 11 ins in length. Trailer truck journals are as large as 8 × 14 ins.

Wheels.

8. Materials. Cast iron wheels, of which the treads and flanges have been chilled to give added surface hardness, are still largely used in freight service. Steel tired iron wheels, or forged or rolled all-steel wheels, are almost exclusivly used for heavy passenger service.

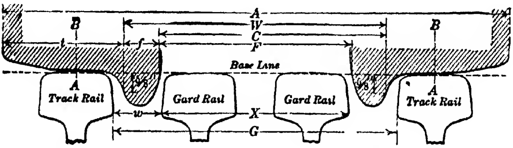

Fig. 2.

9. Tread and flange, for Master Car Builders' standard cast iron wheels, and their relations to the rail heads (including gard rails) are shown in Fig 2.

A =	overall gage	= 5′ 4⅜″;	W =	wheel gage	= 4′ 7 11/16″;
C =	check "	= 4′ 6 29/64″;	F =	flange gage	= 4′ 5 7/32″;
f =	flange thcks.	= 0′ 1 15/64″;	t =	tread	= 0′ 4 11/32″;
X =	gard rail and wing rail gage				= 4′ 5″;
G =	track gage	= 4′ 8½″;	w =	flangeway	= 0′ 1¾″.

Wheel diameter is measured on center line, *A B*, of rail.

10. Standard or usual diam, for all car wheels, 33 ins. Wt of each wheel, 620 lbs for 30-ton capacity car, to 720 lbs for 50-ton.

11. Coning of wheel treads. In order to obviate or diminish the resistances which would occur under a wheel with a cylindrical tread, when rounding curvs, (see Train Resistance, ¶ 36, p 1061), the transition, from the tread to the flange of the wheel, is made by means of a curv, or "fillet", of about 1 inch radius, which usually keeps the side of the flange away from the side of the rail head; and the wheel tread is "coned" (with its greater diam nearer the flanges), in order that the *outer* wheels (traveling always toward the outer rail) may thus be made to roll upon their *larger* diams, and the *inner* wheels upon their *smaller* diams; but, under traffic, the coning becomes reduced, and even reverst, the wheel diam, next the flange, sometimes becoming even less than that farther from the flange. Prior to 1907, the standard coning of the Master Car Builders' Association was 1/38 (1/16 inch in 2 3/8 inches). In 1907, the standard coning was increast to 1/20 (3/32 inch in 1 7/8 ins). The Pennsylvania Railroad found breakages of wheel flanges greatly reduced by the increase of coning. (See Ry Age Gaz, 1912 Jul 19, p 92.)

12. Tires. The function of a tire is to give added strength to the wheels and to resist wear. Tires are either shrunk on to the wheels by reduction of temperature, or clampt on in one or another of many different ways, or both.

Brakes.

13. *A Brake Shoe* is a metal piece so shaped on one side as to conform with the tread and flange of the wheel. Ordinarily, one brake-shoe is provided for each wheel, but "clasp" brakes, having two shoes, one on each side of each wheel, appear to have markt advantages. The two (or four) shoes for a pair of wheels are attacht by *Brake Beams* (frequently trussed to give added strength) placed parallel to the axle, either between the two pairs, or outside, according to convenience, etc, or both, as in the "clasp" brake. *Brake Hangers* are attacht to the brake-beams and trucks in such

a way as to take the forces produced by the friction of the shoes against the wheels and to hold the shoes in place. A system of *Brake Levers*, distributing the brake pressure properly to all the wheels, connects the brake-beams with the source of brake actuating force, *i. e.*, with the shaft of the hand-wheel or with the piston of the air-cylinder, or with both.

14. Air brakes. For the operation of the brakes by comprest air, each car is provided with a *Brake Cylinder*, fitted with a piston connected with the system of brake levers. Each car is equipt also with a *Brake Pipe* running its entire length. The brake pipe has a flexible hose at each end, and connections whereby the entire line may be joind together, and also with one or two steam-operated *Air Compressors*, carried on the locomotiv. A *Brake Valv*, placed in the locomotiv cab, enables the engineer to control the brakes on the locomotiv and thruout the entire train.

15. "Straight" air brake. In this brake, the comprest air passes from the compressor (or from a reservoir of comprest air) on the locomotiv, thru the engineer's brake valv, and the brake pipe, directly into the brake cylinders; thus applying the brakes. Its operation, however, is not rapid enough for long trains, and has the very great disadvantage that any failure of the air supply, as by a burst hose, will result in failure of the entire system; and this is most likely when the demand upon the system has been heaviest.

16. The "automatic" air-brake practically overcomes these objections. Each car carries an *Auxiliary Reservoir* of comprest air, and is provided with a special elaborate valv, known as a "*Triple Valve*", operated by differences in pressure between the brake pipe and the car auxiliary reservoir. The essential feature is that a reduction in pres, in the brake pipe (causd either by the operation of the engineer's brake valv, by an emergency valv on a car, or by a failure of the train line) so operates each triple valv that air passes thru it from the auxiliary reservoir of each car into the brake cylinder. To release the brakes, the engineer sets his brake-valv into such position as to restore the normal pres in the train-line; whereupon the triple valvs permit the escape of the air from each brake cylinder, and suitable springs ensure the release of the brake shoes from the wheels. The engineer's brake valv has several positions, by means of which the brakes may be either (1) gradually releast, (2) all held as they may have been set, (3) gradually applied, or (4) instantly applied.

17. "High speed brake." In this the pressures employd are nearly or quite sufficient to skid the wheels in spite of the relativly low fric coef of the brakes at high speed (see "Friction", p 412). But, as the speed of the train is reduced, the air is allowd to escape gradually, so as to avoid skidding the wheels as the fric coef increases.

18. Electric control of the valvs is largely used in "multiple unit" electric train control; and it has been advocated for very long steam trains where even the "automatic air" brake is at times troublesomely sluggish in its operation. On electric cars, an air compressor on each car is operated by an electric motor on that car.

19. Electric brakes have been largely used on electric street cars. In the Westinghouse electric brake the motors of the car are caused to generate electricity which magnetizes a shoe carried directly over each rail. The shoe then clings to the rail, and the resulting drag forces the brake shoes against the wheels. Electric brakes, depending on the rotation of the motors, cannot, however, keep a car standing on a grade.

20. New high-speed brake. The Westinghouse Air Brake Co., together with Pennsylvania Railroad (S. W. Dudley, Asst Chf Engr, Am Soc M. E., N. Y. Section, 1914 Feb 10) very thoroly tested a new air brake, with the following results:—

Train of 12 steel passr cars and modern loco; total lgth abt 1000 ft; total wt abt 1000 tons

Speed, miles per hour,	30	60	80	
Ordinary brake stopt train in		1600 to 1800		feet
New " " " "	200	1000	2000	feet

21. Vacuum brakes have been employd to a small extent. Their operation is much the same as that of the (comprest) "air brake". As it is of course impossible to obtain operating pressures of more than about 12 lbs/sq inch, very large brake cylinders are required; but the apparatus has the advantage that, in case of failure of the air service, the brakes are applied automatically, without the use of a "triple valv".

Miscellaneous.

22. Air signal and steam supply on passenger trains are operated by means of separate lines of pipe, running the length of the train, each connected, between cars and locomotivs, by individual hose connections. The fundamental principle of the air signal is similar to that of the automatic air brake, in that air pres is normally maintaind in the line of pipe, and that the work (here the blowing of the whistle, in the cab), is done by the escape of air, either (1) effected by a valv, which is operated by a signal cord on a car; or (2) from a leak, such as would be caused by the breaking in two of a train.

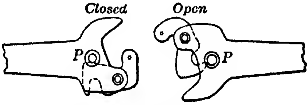

Fig. 3.

23. Couplers, one at each end of a car, are arranged symmetrically with respect to a vertical axis thru the center of the car (the open jaw facing to the left as one stands on the ground facing the car), so that cars and locomotivs may always be coupled together without any reversal of car or coupler. Figure 3 shows two couplers almost engaged, one open and one closed. The knuckles are so latcht by pins, *P, P*, that, with either one open, the cars will be coupled when they come together, without further attention from trainmen. Also, any coupler may be opend, and the cars uncoupled, by means of a lever at a corner of the car, without need for the trainman to go betw the cars. Hoses of train pipes, however, must be both coupled and uncoupled by a man who must go betw the cars; but devices are being introduced by which this also may be accomplisht automatically, especially in multiple-unit electric traction. Car couplers are pivoted to the draft gear, to permit of turning on curvs.

24. The draft gear is a combination, at each end of each car, of a longitudinally-sliding bar, with springs to take up the shock of starting. The springs make it possible, also, to approximate the starting of the train one car at a time, which is valuable because the starting resistances are higher than those of normal running. In *Friction Draft Gear,* friction devices are employd which serv to absorb the recoil of the springs, and thus prevent the accumulation of rhythmically recurring stresses.

Clearance.

25. On bridges, see p 746. **In tunnels,** the Am Ry Eng'g Assn has recommended clearances as shown in Fig 4, betw cen of track and side of tunnel.

26. On curvs an *additional clearance* is necessary and may be computed from the following formulas given by George Paaswell, Asst Engr, Pub Service Commission, New York City, in Engineering & Contracting, 1914 Mar 25, p 367. In Fig 5, let

a = dist betw centers of trucks;
L = length of car;
c = dist from middle of center line of car to center of curvd track;
e = dist from center line at end of car, to center of curvd track;
R = radius of curv.

All units preferably in feet

Then, $c = a^2/8R$; and $e = (L^2 - a^2)/8R$

See also Min clearance on curvs, p 746

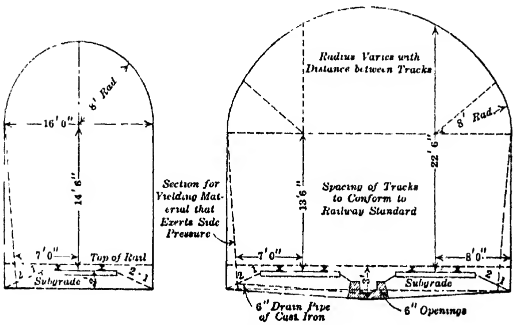

Fig. 4.

27. Where **transition curvs** or **"spirals"** are used, the radius may be taken, nearly enough, as that of the curv at the middle of the car. For the transition curv radius, R_s, at any point, we have $R_s = R_c T/t$; where R_c = circular curv radius; T = length of transition curv; t = dist of the point from beginning (T.S.) of transition curv.

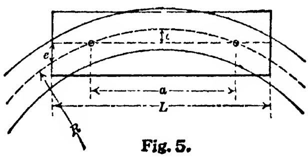

Fig. 5.

28. Tilt of car. In addition to this, allowance must be made, on the inner side of the curv, at least, for the tipping of the car due to super-elevation. This, of course, may be readily computed, given the super-elevation, gage, and height of eav of roof or other critical portion of car.

29. More precise formulas and elaborate diagrams are given for these computations by Mr. Frank H. Carter, in Engineering & Contracting, 1913 Dec 10, pp 650-2.

LOCOMOTIVS

In the following table

Wheel-base is the dist along the rail, betw points of contact of the front and back wheels with the rails.

Tractiv effort, usually betw 0.22 and 0.25 of the wt on all the drivers, is the hor force which the loco can exert, provided the wheels do not slip. It holds good for speeds up to abt 10 mi/hr.

Tractiv effort **at higher speeds** as given by Am Loco Co. Multiply the tractiv effort by the factor corresponding to the speed in question;—

Piston speed, ft/min...	300	400	500	700	900	1200	1600
Factor	.954	.863	.772	.590	.460	.337	.241

Locomotiv Data

The first four lines of the following table are made up from information receivd in 1937 from three large U S mfrs regarding 11 of their very heavy locomotivs; the last four lines from "Statistics of Rys of the U S, by the Interstate Commerce Commission," 1935.

	Loco only, lbs	Tender only, lbs	Wheel Base	Lbs/ft of Track	Tractiv Effort
Heaviest	723,400	402,000	111′11″	10,050	140,000
Av except'y heavy.	600,000	400,000	100′	10,000	100,000
Av heavy..........	486,525	339,220	95′	8,692	85,817
Av mod'y heavy...	400,000	275,000	83′	8,132	81,325
U S av freight....	280,000				54,657
U S av passenger.	250,000				36,225
U S av electric, frt	288,000				
U S av electric, pass	362,000				

Choice of a locomotiv will depend upon the service requirements, and will be limited by clearances of bridges, tunnels, etc, strength of bridges, and wt of rail, this last being taken into account on the assumption that each 10 lbs/yd of rail will carry a load of 3,000 lbs on each wheel; which, for rails weighing 90 to 100 lbs/yd, permits loads of 50,000 to 60,000 lbs per *pair* of driving wheels.

Mileage. The following figures are taken and deduced from Ann'l Report on the Statistics of Rys in the U S, for 1935, Interstate Commerce Commission:—

	Locomotiv Mileage Passenger	Freight	Other Kinds
Total Mileage........	446,148,156	344,745,112	37,711,637
Number of locos......	7,983	27,462	10,169
Mileage per loco			
per year.....	55,887	12,553	37,084
per day......	153.1	34.4	101.6

73. **To ascertain the speed** of a train or other vehicle, on which one is riding, by counting any known equal spaces, such as rail lengths, dists betw telegraf poles, or revs of a wheel, past in a given time. Rail lengths may often be counted by the sound of the wheels passing over the joints; wheel revs by any irregularity of the wheel.

74. Let L = the length of one of the known equal spaces in ft; then

Speed, in ft/sec = number of such lengths past in L secs.

Speed in mi/hr = number of such lengths past in $L \times 3600/5280$ secs, $= L \times 15/22$.

With 30-ft rails, the speed in mi/hr will be equal to the number of rail lengths traverst in 20.45 secs.

CARS

75. Practically all American RR cars, except some cabooses, ore and dump cars, are built with two trucks each, Fig 7, each truck having either two or three pairs of wheels. In a 6-wheeld truck, springs and equalizing levers distribute the load equally, or nearly so, among the three axles. Upon the pivots of both trucks, rests a long rigid "underframe" for the car body. This contains the draft gear which takes the longitudinal stresses. The sides of the cars, so far as practicable, are constructed as girders or trusses.

76. **Material.** Practically all new cars are constructed principally of steel, especially the underframes. Some wood may enter into the bodies of box and passenger cars. Aluminum is being used to a small extent.

77. **Data.** The following table gives approx max and min wts, etc, of cars ordered in the U S in 1936. (Ry Age, '37 Jan 2). Those of highest or lowest capacity were not nec'y those of greatest or least wt.

Type of Car	Length of Body Feet	Weight Empty Pounds	Capacity
Pass, Parlor, Bagg, Mail & Express	64 to 84½	57,100 to 189,000	21 to 136 pass'rs
Box	40½ to 50½	35,200 to 53,000	80,000 to 100,000 lbs
Gondola	24½ to 65½	43,100 to 71,000	80,000 to 200,000 lbs
Hopper	20 to 46	32,600 to 60,400	70,000 to 180,000 lbs
Ore	20	42,375	150,000 lbs
Flat	41 to 70	39,000 to 80,000	80,000 to 200,000 lbs
Tank	29 to 43	34,200 to 75,500	30,000 to 140,000 lbs

78. **Freight cars.** The following is from a table, publisht in Ry & Eng'g Rev, '12 Feb 10, compiled from data from 11 large RRs owning over 450,000 freight cars, for a period of 3 years; av age of all cars, abt 10 yrs. Each car is repaird on an av once a month at a cost of $6.26 each time. Av mileage per car per year, 10,400, which brings repairs to $0.007/car-mile.

79. **Passenger cars.** Av life abt 16 yrs. Av annual repairs, including painting, $300 to $700; for mail and express cars, $150 to $300. The wt of a pass'r car will av fully ten times that of its full load of passengers.

80. **Dump cars** are of very varius design. They may dump either thru the bottom, thru one or more "hoppers" (usually transvers), or thru the sides, in which case

either the sides lift up or swing out, or else the sides remain practically stationary while the entire floor of the car is tilted, thus forming an opening under the side and producing a grade for the material to slide on. In the several makes of cars, various combinations of swinging sides and bottom pieces make possible the delivery of material either between the rails, or at either or both sides of the track. Hopper bottom cars are ordinarily operated by hand, the doors or flaps being tript to open, and being closed by winding up of chains by means of cranks. Tilting-bottom cars are frequently operated by comprest air, and, in some cases, the control is quite elaborate, it being possible to tilt the entire load simultaneously either to the right or the left, or both right and left from alternate cars, under the control of one operator at any point along the train.

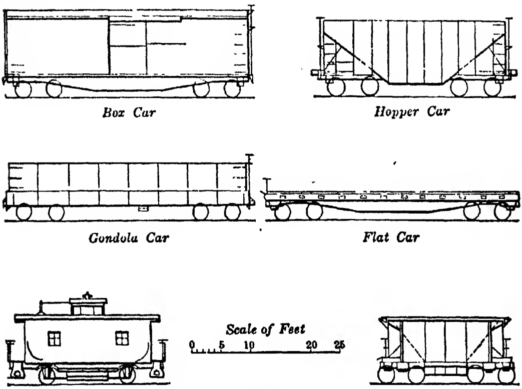

Fig. 7.

81. Ore cars (see Fig 7) are made abnormally short, and of relativly small volumetric capacity, as longer cars are necessarily very inefficient in carrying ores, which are very much heavier than coal or other materials usually carried.

82. Crane cars are used chiefly for clearing up wrecks, for excavation and earth handling generally, for shifting track, and for coaling locomotivs.

83. Locomotiv cranes appear to be coming into high favor for these purposes. They can propel themselves promptly from place to place.

84. Steam shovel cars, and pile drivers mounted on cars, are made in various styles by a number of mfrs.

85. Ballast plows or spreaders are treated under "Track", p 819.

86. Snow plows are either *plows* properly so-called, which shove the snow from the track (to both sides for single track, and to the right for double track); or they are of the *"rotary"* type, in which a large cutting wheel, at the front end, on a hor longitudinal axis, is caused to revolv by powerful engins, often driven by a full-sized locomotiv boiler, and which disposes of the snow largely by virtue of the centrifugal force generated in the cutting-wheel. On steam roads the plow is forced into the snow by one or more

pushing locomotivs behind it; whereas, on electric street roads at least, the plow or *sweeper* (which really sweeps and does not employ centrif force) is forced ahead by its own power, the brooms being rotated by independent motors. Some plows are so arranged that the deflecting surfaces may be forced outward by comprest air (when clearance is sufficient) and so throw the snow further from the track, and therefore with less chance of its return.

87. **Flangers** are pieces, usually of sheet iron or steel, so shaped and arranged as to be lowered onto the rails directly in front of the wheels, to remove any few inches of snow or ice that may be on the rail or along its inner face. They are sometimes fitted to locomotivs, and usually to plows and "rotaries".

88. **Clearance cars** are designd for readily determining the proximity of objects along the road. The clearance cars built by the Pennsylvania and Baltimore & Ohio R R's have mounted, over one of the trucks, a frame transversely of the car, the limits of which are somewhat less than the probable minimum clearances of the road. To this frame are attacht, by means of pivots, at intervals of about a half foot, movable arms, which project about two feet from the frame. Each arm is provided with a scale, so graduated as to show directly the number of inches inwardly that it may have been deflected from its extreme position. The car is run along the track, at about 4 mi/hr, where various objects, as bridges, stations, tunnels, etc, are past; the arms are deflected until they clear, and the deflections are observed and noted. Corrections must of course be made, to provide for the degree of curv, if any, and for the distance between truck pivots of any cars to be operated over the track. In addition to the clearance frame, with its fingers, one of the trucks is so connected with a pointer and dial as to show directly the degree of curvature, while a pendulum, free to swing transversely, is so connected with another pointer and dial as to show directly the super-elevation of either rail. See also "Clearance", ¶ 25.

89. **Inspection and hand cars** range, in elaborateness, from simple trucks with geard hand-levers, up to the combination locomotiv and car, used by officials of the road. Many of these, however, are now being driven by gasoline motors; which, while requiring more skill to operate them than hand cars, can make very high speeds, and can usually keep out of the way of trains. Some are so built that their wheels and axles form a metallic circuit, which operates the automatic signals and so protects the car from trains on the same track; but many of them have the wheels insulated, and must therefore run under train orders from tower-men.

90. **Track recording cars.** See under Track Laying and Maintenance, p 821

91. **Dynamometer cars.** See under Train Resistance, ¶ ¶ 56, etc, p 1067.

92. In **wrecking outfits** there is usually a powerful steam crane car and a number of other cars, carrying miscellaneous equipment, and sleeping and dining facilities. They carry rails, ties and switch-parts, car-trucks, assorted screws, nuts and bolts; tools of many kinds; hoisting equipment of pulley-blocks, chains, ropes, wire-cable, hooks, wooden blocking; also powerful portable lights, fire extinguishers, linemen's outfits with telefone, emergency medical cases, car replacers, etc.

93. **Car replacers** are made in pairs, and are castings so formed with grooves or flanges that, when placed on the ties and adjacent to the rails, they will guide each pair of wheels back onto the rails as the car is forced along the track. They are often provided with lugs, to fit around, or to be forced into, a tie, and with notches, to receiv temporary spikes, to assist in holding them in place.

94. **Loading standards,** as establisht by the Master Car Builders' Assn, are given in a pamflet obtainable from the Secretary.

Old Colony Bldg, Chicago, Ill. The aim is, of course, to load the cars as evenly as possible, to hold the load in place, and to provide for curvs and inequality of track where the load extends over more than one car. Where the load is long enough for two or more cars, it may be supported on two improvised pivots, one on the front and one on the rear car. If the material must be supported midway, metal bearing plates are provided to permit of easy sidewise sliding. Where more than two cars must be used, the extra car usually takes no load and acts merely as a spacer. Some loads of three-car lengths, as plate girders, may be loaded entirely on the central one of three cars, the other two being spacers. Piles of lath, barrels, pipe, shingles, etc, must all be suitably held in place by side verticals and lashings, etc.

TRAIN RESISTANCE

GENERAL.

1. The forces (or force components) acting upon a train in a direction parallel with the track, may be classified as

(a) "moving" forces; tending to start or accelerate the train;
(b) resistances; tending to hold or to retard the train.

2. Locomotiv tractiv force, gravity, wind and inertia may act either as moving forces (a), or as resistances (b), according to circumstances; but friction (external and internal) curvature and still air necessarily exert *resistances* (b).

3. In any given case, the train resistance, F, is the sum of the resistances acting in that case.

4. The tractiv force, exerted, by the steam, thru the loco, has to move the loco and tender, as well as the cars; but often the "resistance" is taken as that of the cars alone, or that which opposes the pull of the draw-bar behind the tender.

5. Components of train resistance. Let

F_n = normal res = the total res upon a straight level track, train at rest or at uniform speed, in still air, and at normal temperatures
= the res to which every train is necessarily subject;

F_g = grade resistance;
F_c = curv resistance;
F_w = wind resistance;
F_i = inertia resistance, due to velocity changes.

} Incidental resistances

Then, for the total resistance, we have:—

$$F = F_n + F_g + F_c + F_w + F_i \quad \ldots\ldots\ldots (1)$$

6. Unit Resistance. Let W = the weight of the train. Then the quotient, $f = F/W$, is the resistance *per unit of weight*, or unit res. Similarly, f_g, f_c, etc., denote the unit grade res, curv res, etc., respectively. Any resistance may be exprest in terms of an *equivalent grade*. See ¶ 33.

NORMAL RESISTANCE

7. The normal resistance, f_n, is the resistance, per unit of weight, on a straight, level track, at uniform speed, in still air. Of the total resistance, it is that portion to which every moving train is always necessarily subject. For incidental resistances, see ¶ 31, etc.

Components of Normal Train Resistance, f_n;

8. (a) friction betw the rail-heads and the treads and flanges of wheels;

(b) resist due to undulation of track under a moving train;

(c) internal friction of cars and locomotiv;

(d) resistance of still air.

Friction between wheels and rail-heads.

9. When the wheel-flanges run clear of the rail-heads, we have, normally, betw rails and wheel-treads, only rolling fric (see p 414, ¶ 193); and this is small in amount where track and rolling stock are in good order; but the sliding fric, betw rail-heads and wheel-flanges, may be of considerable amount, especially where there is oscillation or side wind, (see ¶ 44), and is often accompanied by lateral sliding of the treads on the heads. On curvs, the two rails are of different lengths, and we have longitudinal fric betw tread and head. The conditions vary so greatly, on different roads, and from moment to moment with the same train, that it is impracticable to establish useful rules for this item, or for the next.

10. Resistance due to undulation of track under a moving train is of course greatest on yielding rails and roadway.

11. The internal friction of rolling stock consists chiefly (that of locomotivs partly) of *journal friction*. Its value, in pounds per ton, is

$$f_j = 2000\, c\, d/D \quad \ldots\ldots\ldots\ldots (2)$$

where c = the fric coef of the journal rotating in its bearing, d = the journal diam, and D = the wheel diam. This assumes d/D constant; and, in practice, an *average* value of d/D may usually be estimated for a train.

12. *Journal and rolling resistances combined.* It is difficult to determin these, independently of the other normal resistances. Experiments, made for the purpose, appear to have been unreliable. From coasting experiments, Wellington deduced 4 to 6 lbs per ton of 2000 lbs.

13. *In locomotivs*, (Am Loco Co., Bulletin 1001, Feb. 1910), the friction of driving wheels, pistons, valvs, crossheads, etc., is taken at 22.2 lbs per 2000 lbs of wt on drivers. *Journal friction*, of loco truck and trailing wheels, and of tender wheels, is taken as equal to that for cars.

14. Normal air resistance, F_a. Air res in still air. (See also wind res, F_w, ¶ 44). The evidence is highly conflicting. Prof. W F. M. Goss, Western Ry Club Procs, 1898, April 25, p 347; reports expts made in a large closed rectangular conduit, in which air currents of known velocities impinged directly upon the front ends of fixt trains of from 1 to 25 model cars, about 3.5 ins wide, 4.5 ins high, 12 ins long, each connected, by dynamometer, with a fixt base. Prof. Goss derives the following formulas, in which it is assumed that the linear dimensions of the actual rolling stock are 32 times those of the models on each linear dimension; that freight cars are 33 ft long, and passr cars 66 ft.

Let

F_a = total atmospheric resistance on actual train, in lbs;
V = velocity, in miles per hour;
L = length, in feet, of any train, including loco & tender;
l = length, in feet, of any train, excluding loco & tender;

then, for the entire train: $F_a = 0.0003\ (L + 347)\ V^2$....(3)
for cars alone: $F_a = 0.0003\ (l + 53)\ V^2$....(4)
for loco & tender: $F_a = 0.125\ V^2$ ....(5)

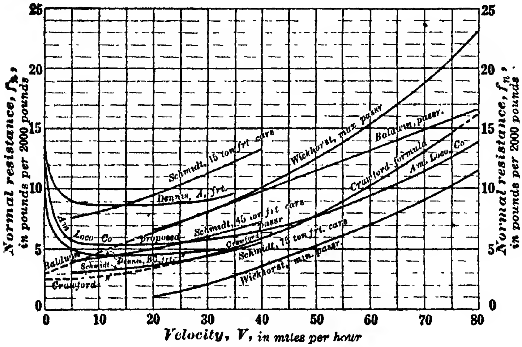

Fig. 1.

Prof. Goss regards these formulas as giving results varying not more than 15 to 20 per cent from the truth in practice.

Unit air resistance, f_a, $= F_a/W$, where W = weight of train in tons of 2000 lbs.

15. Air resistance is increast by *spaces between cars*, by *open side doors* of box cars, and by *differences in heights of cars*, as where flat and box cars alternate in position in a train. "It pays in coal to incur some trouble and delay in putting box cars together. That also enables the brakeman to get along the train more rapidly." (Angus Sinclair, "Locomotive Engine Running and Management", 1891, p 375.)

16. *Head air resistance of locomotiv* is assumed as $0.002\,V^2 A$; where V = vel, in miles per hour, A = cross-section area of locomotiv, usually taken at 120 sq ft. Am Loco Co Bulletin 1001, 1910, Feb.

Factors affecting normal resistance.

Starting.

17. When starting a train (see Fig 1), the value of f_n is much higher than when running. Starting may be facilitated by backing up sufficiently to slacken the couplings, so that the train is started one car at a time.

18. A. C. Dennis, Am Soc C E, Trans Jun 1903, Vol 50, p 1, found that, "after the train has stood for some time, the resistances are abt 2 lbs/ton above the normal until the train has been run enough to get the journals well lubricated and warmd."

19. A. K. Shurtleff, Am Ry Eng & M of W Assn, Bulletin 84, Feb 1907, pp 98, etc., found that, above the freezing pt, the av freight train can be started, on a level, with a draw-bar pull of 18

lbs per ton of 2000 lbs: but freezing weather, or careless starting, may increase this to 25 or 30 lbs per ton. On the other hand, "where a stop was but for an instant, trains were started with 6 lbs. per ton draw-bar pull."

Running.

20. Effect of distance run. With increase of dist run, after a stop, the journals become warmd, their lubrication improves, and the resistance is thus diminisht. During the first mile or two of a run, even with uniform speed and constant air temp, the normal resistance, f_n, may be as much as 50% above the min, which is not reacht until the train has run about 8 or 10 miles in warm weather, and about 35 miles in cold weather. With heavy cars and high speeds, the dist required for reaching min f_n, is less than with light cars and low speeds; the wt on the journals and increast speed aiding in the heating of the journals and in the consequent liquefaction and distribution of the lubricant. (Prof. Edw. C. Schmidt, Central Ry Club; Ry Age Gazette, 1912 Jan 12.)

21. Increase of Speed. Fig 1. The high normal res, experienced in starting, decreases very rapidly as the speed increases to say 5 miles per hour. From say 5 or 10 to 30 or 35 miles per hour (embracing usual freight train speeds) f_n increases slightly, and then more rapidly with further speed increase.

Fig 1 shows curvs of f_n according to experiments and formulas, as follows:—

Experiments.

22. A. C. Dennis, 1902. Am Soc C E, Trans, 1903 June, Vol 50, p 1. Total run, over 3000 miles. Curvs *A* and *B-C*. Runs made with

(*A*), 105 empty box cars, track frozen solid, rail good;
(*B*), 47 loaded box cars, track frozen solid, rail good; net/tare = 2;
(*C*), 52 loaded box cars, track soft; net/tare = 63/27.

Results (*B*) and (*C*) practically identical.

23. The resistances (compensated for velocity *changes*, see ¶¶ 45-52) seemed to be "greater than normal when increasing the speed, and less when decreasing". By coasting tests, locomotiv res, per unit of wt, was found to be about equal to that of *empty* cars.

24. Max H. Wickhorst, 1900, on the **Chicago, Burlington & Quincy R. R.,** between Chicago and Burlington, Ill. (206 miles). Eng News, 1901, Oct 31. Five runs, with dynamometer car, 2 baggage and 2 mail cars; 3 runs loaded, 180 tons, av 55 mi/hr; two runs light, 160 tons, av 27.5 mi/hr. Mean temp, 70° Fahr; wind very light. Very numerous observations. The two curvs show, respectivly, the approx maxima and minima

25. Prof. Edward C. Schmidt, 1910, University of Illinois Bulletin, Vol VI, No 39. Very elaborate tests of 32 ordinary freight trains, wts 747 to 2908 tons per train, 26 to 89 cars per train, averaging from abt 15 to 70 tons per car; over av track, in good condition; air temp from 34° to 82° Fahr. See three selected curvs, Fig 1; vels from 5 to 40 mi/hr.

Formulas.

26. American Locomotive Co. Bulletin 1001, 1910 Feb, p 10; R. R. Age Gaz, 1909, Sep 10, p 455:

$$f_n = 5.4 + 0.002\ (V - 15)^2 + 100/(V + 2)^2 \quad \ldots\ldots(6)$$

in which V = vel in mi/hr.

27. J. G. Crawford, Eng News, 1901, Oct 31. Based upon Wickhorst's **C, B & Q** expts, ¶ 24. For vels betw 25 and 75 mi/hr.

$$f_n = 2.5 + V^2/468 = 2.5 + 0.0021\ V^2 \quad \ldots\ldots\ldots\ldots(7)$$

28. Baldwin Locomotive Works, straight-line formula. R R Gaz, 1899, Mar 17. Based upon expts on Phila & Reading system, betw Camden and Atlantic City, 55.5 miles without stops.

$$f_n = 3 + V/6 = 3 + 0.167\ V. \quad \ldots\ldots\ldots\ldots(8)$$

Cold.

29. The American Locomotive Co. (Bulletin 1001, 1910 Feb.) ıakes the following reductions from the tonnage hauld at normal emps;—

Temperature, Fahr.	Deduct
45° to 25°	8 per cent
25° to 0°	16 " "
Below 0°	25 " "

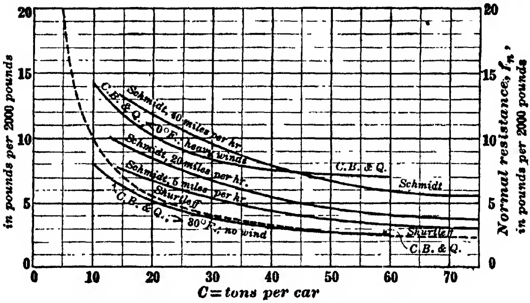

Fig. 2.

Effect of weights of cars.

30. Fig 2 shows the effect of weight of freight cars, and, inci- ɜntally, to some extent, of velocity, upon the normal resistance, ; as follows :—

C B & Q expts, R R Age Gaz, 1909, Aug 27, Sep 3;

Prof. Edward C. Schmidt, expts, Illinois Central R R. See also 25.

The dotted curv represents the formula of A. K. Shurtleff, Am y Eng & M W Assn, Bulletin 84, Feb 1907, p 99 :—

$$f_n = 1 + 90/C \quad \text{.........................} (9)$$

here C = av weight of loaded car, in tons of 2000 lbs. This ırmula is based upon expts on two railroad systems. Total runs, ver 3000 miles, 19 to 41 tons per car. Track varied from "mud ıllast, with medium line and surface, to first class track, well bal- sted, with good line and surface......from valley lines to moun- ıin lines and grades." Temp from 0° to 60° Fahr.

INCIDENTAL RESISTANCES. See ¶ 5.

31. In addition to the normal train res, we must usually take ccount of the incidental resistances:

F_s, due to grades;	F_w, due to wind;
F_c, " " curvature;	F_i, " " inertia.

Grade Resistance

32. On any grade, let a = the angle with the horizontal. hen, for the res, parallel with the slope, necessary to prevent ıovement of a wt, W, down the slope; we have;—

$$_s = W \sin a; \text{ and, since } f_s = F_s/W; \; f_s = \sin a \ldots. (10)$$

But, except on very steep railroads, the slope is so slight that, approx, $\sin a = \tan a$. Therefore, if L = the hor dist betw two points, and h = their diff of elev; we have;—

$$F_s = W \tan a, \text{ and } f_s = \tan a = h/L \quad \ldots\ldots (11)$$

33. The equivalent grade, s_e, is that grade which will produce the same tendency along the track as that due to a given resistance; or that grade where the tendency to slide downward is just balanced by the given res. Hence, any unit res, f, $= F/W$, may be exprest as a grade. For various conversions, see Fig. 3.

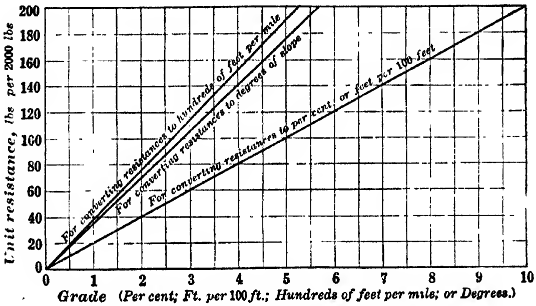

Fig. 3.

34. Units of grade resistance. Let

s = grade, in feet per 100 feet;
S = grade, in feet per mile = 52.80 s.

35. Then, for the **grade resistance,** in lbs per ton of 2000 lbs, we have;—

$$f_s = 20\,s = 0.3788\,S \quad \ldots\ldots\ldots\ldots\ldots (12)$$

and, for any unit resistance, f, due to any cause, we have;—

equivalent grade, in ft per 100 ft, $= f/20$ ..... (13)

Ruling grades; see "Operation Cost", p 1084.
Momentum grades; see p 1076, ¶ 40.
Work done and lost on grades; see p 1075, ¶ 30.
Effect of Length of Grade on Tractiv Force; see p 1076, ¶ 37.

Curv Resistance.

36. At any point on a curv, an axle, with fixt cylindrical wheels of equal diams, tends to travel forward in a direction perp to itself and tangential to the center line of the track, remaining parallel with itself. Hence, the flange of the outer front wheel tends to press outwardly against the head of the outer rail, causing sliding friction betw the sides of flange and of rail head; and this fric opposes the rotation of the wheel. Moreover, the head of the outer rail, by its hor reaction upon the wheel flange, pushes the outer wheel (with its axle and mate wheel) toward the cen of the curv, compelling both wheels to slide laterally across their respectiv rail heads, and thus causing sliding fric betw wheel tread and top of rail head. This, of course, is combined (according to the resolution of motions and forces) with any longitudinal slipping, as it takes place; (¶ 37).

All this is notably the case with the first wheels of a car or train. On the following trucks, the direction of the traction coincides, at each truck, with a chord to a portion of the curv; and thus tends to reduce the pres of said following trucks against the outer rail.

37. Again, the axles must be constantly swung, horizontally, from positions parallel with themselves, and forced into positions more nearly radial to the curv; and this requires that one or the other wheel, or both wheels, must be slid, longitudinally of the track. See also Corrugation, under "Track", p 793, ¶ 91.

38. In order to obviate or diminish the resistances thus causd, the wheel treads are "coned". See Rolling Stock, p 1040, ¶ 11.

39. The resistance, F_c, due to curvature, is influenced by many circumstances; such as diam of wheels, tightness of gage, shape of wheel treads (whether more or less conical), lengths of rigid wheel bases (see ¶ 43), kind of coupling, condition of track, elev of outer rail, length of train (affecting obliquity of traction: See end of ¶ 36).

40. Unit curv resistance is usually taken as varying, other things equal, directly with the sharpness of curvature; or, for curv resistance, in lbs per 2000 lbs, on a D° curv:—

$$f_c = D f_1 \qquad (14)$$

where D = sharpness of curvature, in degrees;
f_1 = the curv res, in lbs per 2000 lbs, on a 1° curv.

41. f_1 is usually taken as varying, (with character and condition of track and of rolling stock,) between 0.5 and 1.5 lbs per 2000 lbs. In compensating for curvature, on grades, (see p 1078, ¶ 51), it is usual to allow betw 0.6 and 0.8 lbs per ton. See Fig 4.

42. Fig 4 shows the unit curv res, f_c, by Eq (14), in various units, corresponding to sharpnesses from 0° to 20°, and for values of f_1 from 0.5 to 1.5. The *dotted* radial line gives, for diff degrees of sharpness, the sweep, in degrees, of a mile of curvd line of given sharpness; and the dotted curv gives the ft of line per degree of sweep.

$$\text{Feet per degree of sweep} = 100/D \qquad (15)$$

$$\text{Degrees of sweep per mile} = 5280\,D/100 \qquad (16)$$

These two dotted diagrams represent purely *geometrical* conditions, without regard to *resistance*.

43. Effect of length of wheel-base. Prof. Wm. G. Raymond, R R Gaz, 1906, Aug 17, makes the curv resistance,

$$f_c = 0.4 + D(0.205 + 0.035\,B) \qquad (17)$$

where D = sharpness of curvature, in degrees,
and B = length of wheel-base, in feet.

43a. Effect of velocity. It is probable that curv resistance, f_1, per degree of sharpness, (like normal res), varies with velocity, somewhat as indicated by Fig 1. In other words, we may expect to find it (1) high at very low speeds (because the value of the fric then approaches that of static fric), (2) falling to a min at moderate speeds, and (3) increasing again at higher speeds.

Wind resistance, f_w.

For *normal* resistance, f_a, due to still air, see ¶ 14.

44. Head winds of course oppose, and winds in the opposit direction assist, the forward movements of trains; and side winds, by forcing the wheel flanges against the rail heads, increase the resists; but little is known as to the extent of these influences; and, as their exertion cannot be controlled or foreseen, their effect is practically incalculable. A margin must nevertheless be made for them, according to judgment, in estimating the ability of engins to move given loads under given conditions. Where the vel of head wind, or of tail wind, can be estimated, the vel of head wind may be added to, and that of tail wind subtracted from, the train vel,

and the sum or diff used in connection with ¶ 14. For "heavy winds", the Am Loco Co deducts 8% from the tonnage hauld in still air. Bulletin 1001, 1910, Feb. See also two C B & Q diagrams in Fig 2.

Inertia.

45. To accelerate a train requires a "moving force"; and to retard it requires a resistance. Conversely, a train, undergoing accel, may be said to offer a res, due to inertia; and one being retarded may be said to exert a force, due to inertia. In order to compute the total train res, when vel is being changed, we must include the res due to inertia; and, for this, we must know or assume the weight, and either (a) the rate of accel, or (b) the vel, and the dist within which a given vel change takes place.

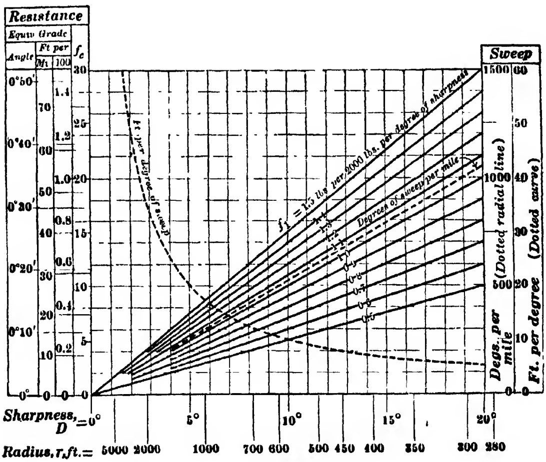

Fig. 4.

46. (a) When a weight falls freely, the accel of vel, due to the force, W, of gravity, is $g = 32.2$ ft per sec per sec; and the accel, A, of any given body, is directly proportional to the unbalanced force, F_i, acting upon it; or $g/A = W/F_i$. Hence, for the force or res, F_i, due to inertia, and producing an accel or a retardation, A, we have:—

$$F_i = \frac{W}{g} A = M A \quad \ldots\ldots\ldots\ldots (18)$$

where $M = W/g =$ the mass of the body.

(b) Let a car move on a horizontal track, and let

W = the car's weight; $M = W/g =$ the car's mass;
V = the car's velocity;
F_i = the unbalanced hor force, acting upon the car;
L = the dist, and T = the time, within which F_i can produce or destroy V;
K = the car's kinetic energy $= F_i L =$ the corresponding work.

Then (Mechanics, pp 343, etc., Art. 19)

$$K = MV^2/2 = F_t L; \quad \ldots\ldots (19)$$

and

$$F_t = K/L = \frac{\frac{1}{2} M V^2}{\frac{1}{2} T V} = M \frac{V}{T} = M A \quad \ldots (20)$$

47. Values. The following may be taken as indicating the range of accelerations, A, and of values of f_t, to be expected in practice.

A = acceleration in ft/sec/sec = $0.0161\ f_t$
f_t = force in lbs per 2000 lbs = $62.1\ A$

Starting accelerations;

With very light trains for suburban service, where high accels are essential, the forces or resists, needed to overcome inertia, may greatly exceed all the other forces or resists.

Rotational Inertia.

48. In addition to the inertia due to motion of the car, as a whole, along the track, we have, in the revolving wheels and axles, an *additional* inertia, due to their rotation alone; and, like the linear inertia of the car, this rotational inertia of the wheels and axles exerts a resistance during acceleration, and a "moving force" during retardation. We here have to take account of the gyration radius (p 352) of the rotating parts. This is less than the wheel-tread radius.

Let

R	=	wheel-tread radius;	r	=	gyration radius of rotating parts;
V	=	rectilinear car velocity	v	=	rotational vel of point at end of r;
	=	rotational vel of point on wheel-tread about wheel axis;			
A	=	corresponding acceleration;	a	=	corresponding rotational accel;
K	=	car energy;	k	=	rotational energy of wheels, etc.;
F_t	=	hor force, applied at, and normal to, wheel axis, and producing A;	F_r	=	tangential force, at end of r, producing a;
			F_a	=	hor force, at axis, producing a;

W = car weight; w = weight of rotating parts;

M = car mass = W/g. m = mass of rotating parts = w/g.

Then (since $V/v = A/a = R/r$) we have :—

$$k = \tfrac{1}{2}\, m\, v^2; \qquad K = \tfrac{1}{2}\, M\, V^2; \qquad \frac{k}{K} = \frac{m\, v^2}{M\, V^2} = \frac{m\, r^2}{M\, R^2} = \frac{m}{M}\left(\frac{r}{R}\right)^2$$

$$F_a = F_r \frac{r}{R} = m\, a \frac{r}{R} \qquad F_i = M A; \qquad F_r = m\, a;$$

$$\frac{F_a}{F_i} = \frac{m\, a\, r}{M\, A\, R} = \frac{m\, r^2}{M\, R^2} = \frac{m}{M}\left(\frac{r}{R}\right)^2 = \frac{k}{K} \quad \text{........(21)}$$

49. Because the masses of the axles lie close to their axes of rotation, their rotational inertia is so small that it is commonly neglected. But car wheels and electric motors are of considerable wt and diam, and their rotational inertia forms a material portion of the total car inertia.

50. Values. In ordinary car wheels, r/R, ($= v/V$), is usually about 0.7, varying somewhat with wheel design; and the ratio, w/W, betw the wt, w, of the wheels, and the total wt, W, of car and load, varies (chiefly with the extent to which the car is loaded), usually betw 0.17 and 0.06.

Hence, $\dfrac{k}{K} = \dfrac{m\, r^2}{M\, R^2}$, may be expected to range from

$0.7^2 \times 0.17$ to $0.7^2 \times 0.06$, or say from 0.085 to 0.03; or, as an average, say $k/K = 0.05$; and $K + k = 1.05\, K$.

51. As determined by the Westinghouse Mfg. Co., and as computed from data furnisht by the General Electric Co, k/K, in *electric motors*, varies betw wide limits. In general, however, it lies betw 0.05 and 0.15 for av street and interurban cars, neglecting the wheels and gears, for which, in such cars, k/K appears to be about 0.10.

With electric locomotivs, the range is much wider; certain gearless electric locos having k/K less than 0.10, including wheels; while in other low-geared freight locos, k/K may be as high as 0.60.

Velocity Head.

52. Let

$H = V^2/2g$ = head due to hor vel of car;

$h = v^2/2g$ = head due to curvilinear vel of point at end of gyration radius, r.

For a given mass, $h/H = k/K$. Hence, taking $k/K = 0.05$, or $K + k = 1.05\, K$, we would have,

$$H + h = 1.05\, H.$$

From eq (20), ¶ 46, substituting $(K + k) = 1.05\, K$, for K, we have :—

$$F_i = 1.05\, K/L. \qquad \text{Hence, } F_i = 1.05\, W\, H/L; \text{ and}$$

$$f_i = \frac{2000}{W} F_i = \frac{2100\, H}{L} = \frac{2100\, V^2}{2\, g\, L};$$

where V = hor vel of car, in ft per sec = $(1.466..) \times V_m$, where V_m = vel in miles per hour. Hence, we have :—

$$f_i = 70.15\, V_m^2/L \quad \text{................(22)}$$

SUMMARY.

53. Fig 5 gives a general view of the relations betw the normal resistance, f_n, and the three calculable incidental resists, f_s, f_c and f_i, due to grades, to curvature, and to velocity increases, respectively.

The V scale refers only to the f_n and f_i diagrams; while the s and D scales refer to the f_s and f_c diagrams respectively.

Note that the right hand vertical scale relates to the f_c diagram only.

The f_n diagram represents the Am Loco Co formula of Eq (6), ¶ 26:—

$$f_n = 5.4 + 0.002(V - 15)^2 + \frac{100}{(V + 2)^3},$$

where V = speed in miles per hour.

The f_s diagram represents eq (12), ¶ 35,

$$f_s = 20\,s,$$

where s = grade in ft per 100 ft.

The f_c diagram represents eq (14), ¶ 40,

$$f_c = Df_1,$$

where D = degree of sharpness, and f_1 = 0.8.

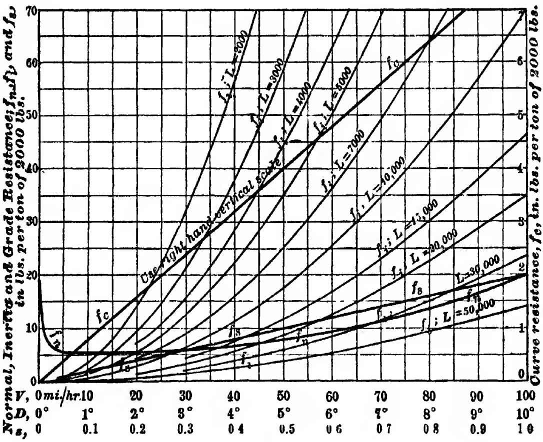

Fig. 5.

54. The several f_i curvs represent the sum of linear and rotational inertia resists, where sum = 1.05 × linear res, and L = the dist, in ft, in which the vel change is effected. In using these curvs, it is necessary to take out the two resists, one for the initial and one for the final vel (each for the dist L in question). Then, inertia res = *difference only* betw these two resists, each of which, alone, represents the res when one of the vels is *zero*.

$$f_i = 70.15\,V_m^2/L; \qquad \text{eq (22), ¶ 52.}$$

55. Example. Let the wt, W, of train be 1500 tons; the up-grade, s, = 0.05 ft per 100 ft; the curv sharpness, D = 3°; and let the vel, V, be increast in a dist, L, of 10,000 ft, from 30 to 40 mi/hr; (mean vel, 35 mi/hr).

Then, from Fig 5, we have	lbs per ton
Normal resistance, f_n, Am Loco Co (V = 35 mi/hr)	6.2
Grade " f_s (= 20 × 0.05)	1.0
Curv " f_c (= 0.8 × 3)	2.4
Inertia " f_i (= 11.2 − 6.3)	4.9
Total unit resistance, f, ...	14.5

Total resistance, $F = fW = 14.5 \times 1500 = 21{,}750$ lbs

Of which there are due
to uniform-speed resistances 9.6 × 1500 = 14,400 lbs.
to speed-increase " 4.9 × 1500 = 7,350 lbs.

DYNAMOMETER CARS

56. The chief function of a dynamometer car is to measure (and record) the **tractiv effort.** The dyn car is placed betw the loco tender and the first car of the train, and the amount of the pull upon its draw-bar then indicates the tractiv effort exerted upon the train exclusiv of the tender.

57. Recorder. The car is usually fitted with apparatus for grafically recording or plotting the various data to be obtaind. This apparatus consists essentially of a large table or frame, fitted up in the car, with a long continuous strip or band of paper, to receiv the record. This band is caused to move longitudinally over the table and under a number of pencils or pens, each of which is capable of more or less lateral movement across the paper.

The movement of the paper may be made proportional either to the dist traveld along the track, or to the time consumed. If the movement of the paper is to be proportional to *distance* traveld, the drum, onto which the paper is wound, or which drives it, is usually geard to an axle, left without brakes, since braking might cause the wheels to slide. The gearing is preferably so arranged that the paper will move in only one direction, whether the car moves forward or back, as otherwise the records would overlap when backing up and moving ahead again If the movement of the paper is to be proportional to *time,* the winding drum may be operated by powerful clock-work, or by a well-constructed fan movement such as that used for the striking action of a clock, or by means of magnets operated by electric contacts made at close intervals by a clock.

58. Pens. The lateral movements of the several pens or pencils are controld, sometimes by electro-magnets, and sometimes by mechanical connections of various kinds, as may be convenient or appropriate.

59. The draw-bar pull was formerly measured by means of a mechanism similar to a weighing scale laid upon its side, so as to measure horizontal instead of vert forces. It is the general practice now, however, to have the draw-bar connected directly with a piston, sliding in a strong cylinder containing oil. A pipe leads from this cyl to a smaller cyl placed at the recording apparatus, and fitted with a piston and spring, as in the ordinary steam-engin "indicator." This then records directly upon the paper, by moving its pen more or less to one side, depending upon the force transmitted thru the oil, from the draw-bar. Another method makes an "indicator" of the main draw-bar cylinder, by fitting it with accurate but heavy springs, and by directly transmitting its movement mechanically to the pen of the recorder. Using either method, leakage of oil past the piston in the cyl must be compensated. This is usually done by means of a special pump.

60. Acceleration. Accelerometers usually depend upon the forward or backward deflection of a pendulum or other eccentrically suspended mass, under the force due to acceleration or retardation. Difficulty has been experienced in preventing violent and misleading oscillations without unduly delaying or restricting the motion. The Wimperis accelerometer, Mins Proc Inst C E (England), 1911-12, Part II, p 420, appears to give good results, the motions of the masses being dampt magnetically. Mr. Wilfred Lewis, of Philadelphia, has used an instrument similar to the common leveling tube; and the behavior of the bubble seems fairly satisfactory; but this device can make no record. Another instrument, experimented with by the Trautwine Company, cannot possibly over-indicate, no matter how sudden the changes of accelerating force.. The apparatus (carried on the car) depends upon the constant dropping of a stream of particles, such as sand, steel balls, or drops of water, from a given point in the apparatus, thru a given height, onto a scale placed at the bottom of the apparatus and lying in the direction in which the accel is to be measured. The particles are releast in rapid succession, and each particle, falling freely, must continue falling with the hor vel it had when releast. Therefore, any change of vel of the car, which occurs during the fall of any particle, shifts the scale under it more or less, so that the particle falls upon the scale at a greater or less distance from the zero (which is immediately under the point from which the particles are releast), in direct proportion to the av accel during the time of falling.

61. Strictly speaking, an accelerometer can measure *acceleration only* when *running* on a *level*. With a train on a *grade*, the effect of the grade increases or diminishes the indications, and, unless correction can be made for this, the indication of accel is correspondingly misleading. On a car or train running without power or brakes (on *any* grade), an accelerometer's indications become a measure of the total *resistance* of the car, or train, as a whole.

62. Lateral forces, due to curvs or inequalities in the track, are frequently measured by an accelerometer placed at right angles to the track, especially on test cars.

63. Time should be recorded when the movement of the paper is proportional to the dist traverst, and a time record is useful even when the paper is moved at a time-rate. It is usually made by a pen deflected by an electro-magnet actuated once every five seconds by contacts in a clock.

64. Distance should be recorded if the paper is made to travel at a time-rate, and a dist record is useful even when the paper is moved in proportion to the *distance*. It is made by a pen, deflected by an electro-magnet, or by gearing from the wheels, every time a certain dist has been traverst. In any case, dist is usually recorded also by an observer using a push-button by means of which he can deflect another pen upon the passage of each mile-post or other object.

65. Speed may be deduced from the records of distance if the paper is moved at a time-rate or *vice versa*. It is, however, preferably plotted by a special pen, which, as the velocity changes, may be deflected from its datum line by mechanical connection with a device similar to a centrifugal governor, or by some other type of speed recorder; or the pen may be so arranged as to be drawn aside from the datum line by means of an electric contact or gearing from the wheels, proportionately with the dist traverst, releast at the end of a given time interval, and allowd to fly back to the datum line, thus giving a record of *average* velocities for successiv short intervals of time. This last device should require no calibrating. Using an additional refinement, only the stepping-up or counting mechanism returns to zero, while the pen remains at the point previously reacht, thus plotting a stept curv instead of a series of ordinates.

66. Air-brake operation is usually recorded by a pen deflected by a piston in a small cylinder connected with the brake cyl of the car.

67. Boiler pressure has been similarly recorded by means of a steam pipe connected with the loco.

68. Wind velocity has been recorded (at least on the University of Illinois Test Car) by the usual Weather Bureau Robinson cup-type anemometer, making and breaking electric contact with every 0.2 mile of wind.

69. Wind direction is recorded (on the same car) by mechanical connection with a wind-vane, whereby the deflection of the pen is kept = to the sine of the angle of the vane, right or left, while the forward or rearward position of the vane is indicated by another pen.

70. Curvs may be recorded by mechanical connection with one of the trucks.

71. Miscellaneous data are largely recorded by hand, by means of push-buttons on the car or loco; this method being used for such items as shovelfuls of coal put into fire-box, opening and closing of fire-box door, opening and closing of throttle, position of reverse lever, etc.

TRAIN DYNAMICS

GENERAL

Tractiv Force, Resistances, Speed, Energy.

1. The movements of a train are governd by the existing relation betw the tractiv force and the resistances. This relation is partly under the control of the enginman. See ¶ 4.

2. Tractiv Force. With a given loco, tractiv force (p 1056) is increast by increast steam admission to the cylinders (as by increasing the boiler output or the throttle opening, or by delaying cut-off), and by increasing the "adhesion" betw drivers and rails (as by sanding the rails). The tractiv force is diminisht by diminisht steam admission to the cylinders and by slipping betw the drivers and the rails.

3. The resistance is increast by the application of brakes or by reversing the loco engins; and is diminisht by releasing the brakes.

4. In practice, however, these operations are complicated by other phenomena. Thus, a material *speed increase* (as by increast steam admission to the cylinders) increases the difficulty of maintaining the increast cyl pressures; while, on the other hand, *as a train slows down,* it becomes easier to maintain said pressures.

5. Again, under certain conditions (Resistance, pp 1057, etc.) the frictional and atmospheric resistances increase when the speed increases. As a result of this, each grade has its limiting velocity, which cannot be exceeded by a descending train, left to itself upon such grade. See pp 1087-8, ¶¶ 37-38.

Effect of inertia.

6. Energy. When speed is being increast, kinetic energy is being stored in the train, and such storage (except when produced by a down grade) requires additional work from the loco. When speed is being diminisht, the kinetic energy, already stored in the train, assists its forward motion

7. For any change of speed, as from v_1 to v_2, the change, in kinetic energy, is

$$W \frac{v_1^2 - v_2^2}{2g} = m \frac{v_1^2 - v_2^2}{2} \text{ ; where}$$

W = the weight, and m = the mass, of the train; and g = gravity acceleration, = say 32.2 ft per sec per sec.

8. The virtual head or velocity head, = the height thru which a body must fall, in order to change its vel from v_1 to v_2, is

$$h_v = \frac{v_1^2 - v_2^2}{2g}. \quad \text{Hence,}$$

$$\text{Change in kinetic energy} = W \frac{v_1^2 - v_2^2}{2g} = W h_v.$$

Where either v_1 or v_2 = zero, we have, vel = v, and
Energy change = $W v^2/2g$ = $W h_v$.

GRADES

9. In considering the establishment of grades, their *effect upon train velocities* is of vital importance.

Virtual Profile.

10. Virtual head; virtual grade; virtual profile. In Figs 1*a*, 1*b* and 1*c*, let *A B C...G* be a given railroad profile; and, in each Fig, let a train, coming from the left, reach *A* with a vel of *v* ft per sec. Let *A a* represent, by the scale of the actual profile, the corresponding or virtual head, $h_v = v^2/2g$. For simplicity, we here neglect the rotational vel of the wheels; see p 1064. At other points, in either Fig, erect ordinates, *B b*, *C c*, *D d*, etc, representing, by the same scale, the virtual heads at those points respectivly. Then, for the condition, see ¶ 13, represented by either Fig, *a b c . . . g* is the virtual profile corresponding to the actual profile, *A B C . . . G*.

11. Let

T	=	the loco tractiv force	parallel to the track
F	=	the total or resultant resist	" "
t	=	$T - F$ = the resultant force	" "
	=	the force causing the accel	" "
F_s	=	the gravity component	" "
F_r	=	the nongravitational resist	" "
		("+" = with T; "−" = against T)	" "
W	=	train weight	acting vert downward
g	=	gravity acceleration	" " "

12. As will be shown, the behavior of the train is governd by the adjustment (partly within the control of the enginman) betw T, F, F_s and F_r.

If T is		F_s is	$T + F_s$ is	F_r is	$F =$	$t\ (= T - F) =$
↗	$< F_s$	−	−	+	$F_s - F_r$	$T - (F_s - F_r)$ $= T - F_s + F_r$
↗	$> F_s$	−	+	−	$F_s + F_r$	$T - (F_s + F_r)$ $= T - F_s - F_r$
→		0	+	−	F_r	$T - F_r$
↘		+	+	−	$F_r - F_s$	$T - (F_r - F_s)$ $= T + F_s - F_r$

13. Figs 1a, 1b and 1c represent three supposable and typical cases, as follows:—

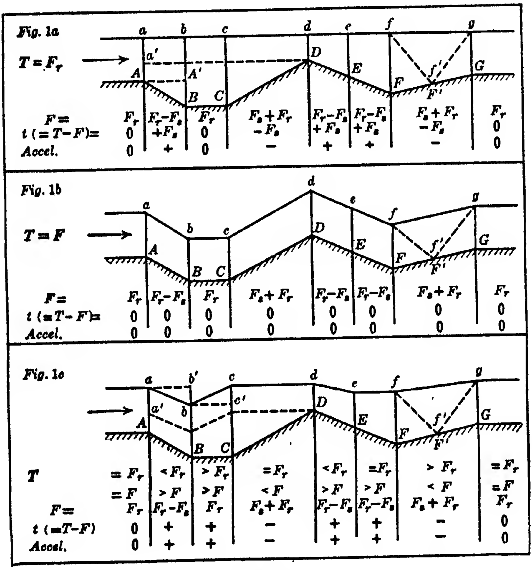
Fig 1*a*. $T = F_r$. Virtual profile horizontal;
Fig 1*b*. $T = F$. " " parallel to actual profile;
Fig 1*c*. Neither of the two foregoing conditions satisfied.

14. Fig 1a. "Frictionless train." We here assume that the tractiv force is maintaind thruout equal to the non-gravitational resistance; or $T = F_r$. The train is then mechanically in the condition of a frictionless body; *i. e.*, all vel changes are those due to gravity alone.

15. Then, in passing from *A* to *B*, the train loses *A' B* in elevation, but gains an equal amount in virtual head due to increase of vel, making its total virtual head, at *B*, $h_v = B\ b = BA' + A'\ b$. Hence, the virt profile, *a b*, betw *A* and *B*, is horizontal, as is also (in Fig 1*a*) the virtual profile, *a b c....g*, for the entire line, *A B C....G*, assuming (as above) that T and F_r are maintained

equal thruout. This is apt to be at least approx the case with light and fast passenger trains on short and moderate grades. Such a condition would continue indefinitely (assuming T maintained $= F_r$), except that if, at any point, the actual grade, $A \ldots . G$, rises to the level, $a \ldots . g$, the train comes to rest, and cannot start again without increase of T over F. See ¶ 21.

16. Fig 1b. Velocity uniform. If the tractiv force is maintained equal to the total resistance (which includes the gravity component), *i. e.*, if $T = F = \pm F_s \pm F_r$; so that $t = T - F =$ zero; then the vel (and, consequently, the vel head, h_v, represented



Figs. 1.

by $A\,a$, $B\,b$, etc) remain constant, and equal to those of the train when arriving at A; and each stretch, $a\,b$, $b\,c$, etc, of the virtual profile, $a\,b\,c \ldots . g$, is parallel with the corresponding stretch, $A\,B$, $B\,C$, etc, of the actual profile, $A\,B\,C \ldots . G$. On *level* stretches, as $B\,C$, we have $F_s =$ zero, $F = F_r$, and, in Fig 1b (as thruout Fig 1a), $T = F_r$, and $b\,c$ horizontal.

17. Fig 1c. Usual case. In general (and especially with heavy frt trains) the relation betw T, F_s, F_r and F, adjusted by the engineman (see ¶¶ 1, 2, 3) to suit existing conditions, fulfils neither the conditions of Fig 1a nor those of Fig 1b.

18. In the assumed case, represented by Fig 1*c*, we have:—

In Fig 1*c*

Section	Grade actual	Grade virtual	Tractiv force, T	Virtual and actual grades	$t\ (= T - F)$ and acceleration
. . . . . A	→	→	$= F_r = F$	parallel	0
$A - B$	↘	↘	$< F_r > F$*	divergent	+
$B - C$	→	↗	$> F_r > F$	"	+
$C - D$	↗	→	$= F_r < F$	convergent	−
$D - E$	↘	↘	$< F_r > F$*	divergent	+
$E - F$	↘	→	$= F_r > F$	"	+
$F - G$	↗	↗	$> F_r < F$	convergent	−
G	→	→	$= F_r = F$	parallel	0

In general; Figs 1*a*, 1*b*, 1*c*,

If the virtual grade is	The tractiv force, T, is	If the virtual and actual grades are	The velocity is
up	$> F_r$	divergent	accelerated
level	$= F_r$	parallel	uniform
down	$< F_r$	convergent	retarded
		coincident	zero

19. The dotted profile, $f\,f'\,g$, in each of the three figures, represents a case where, instead of proceeding continuously from F to G, the train stops, as at F'; *i. e.*, the case where the vel becomes zero, and the two grades coincide.

20. Different Profiles for different trains. Since trains differ as to speed, etc, each train may require its own separate virtual profile; thus, Fig 1*a* represents approximately the probable conditions for fast passenger trains; Fig 1*c* those for freight trains, etc.

21. The virtual profile shows the speeds, and the speed changes, which may be expected of a given train on a given profile. Thus, Fig 1*a* or 1*c*, if, at A, the vel were such that the vel head was only $A\,a'$, the train would stall at D, provided the other conditions remaind as shown; the virtual profile, $a\,d$, in that case, being simply lowered vertically and parallel with itself, thru the dist $a\,a' = d\,D$. See ¶ 15.

*On a down grade, the *total* resistance, F, becomes F_r minus F_s (see ¶ 12); and may thus be very small, or zero, or even a minus quantity. Therefore the loco tractiv force, T, even if less than F_r, may yet be greater than the "total" resistance, F.

22. Head-gain. Fig 1c. In any given dist, as $B\,C$, the non-gravitational head-gain, h_v, (or head-loss, as the case may be), represented by $c'\,c$, is directly proportional to the unbalanced non-gravitational force, t_r ($= T - F_r$ or $F_r - T$), acting upon the train thruout that dist; and the ratio, betw said unbalanced force, t_r, and the train weight, W, is equal to the ratio betw h_v and the dist, L, represented by $B\,C$. In other words,

$$\frac{t_r}{W} = \frac{h_v}{L}; \quad \text{or} \quad t_r = W\frac{h_v}{L}.$$

23. Profile steepness measures force excess. Fig 1c. Similarly, in the distance represented by $A\,B$, there is an excess ($= t_r = F_r - T$) of non-gravitational resist over tractiv force; and the increase in vel and in vel head is therefore less, in Fig 1c, than in the same stretch, $A\,B$, in Fig 1a, where $T = F_r$. The corresponding loss, h_v, of vel head, in $A\,B$, Fig 1c, as compared with Fig 1a, is represented by $b'\,b$. Here also

$$t_r = W\frac{h_v}{L}.$$

The steepness of any line in the virtual profile is thus a measure of the excess of tractiv force over non-gravitational resistance, or vice versa.

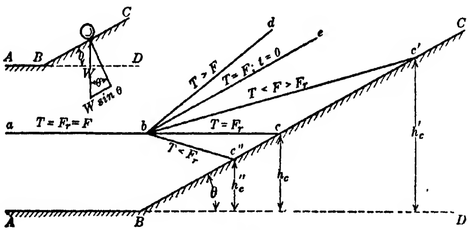


Fig. 2.

The height to which a train will ascend a grade.

24. Fig 2. Suppose a train running, at uniform speed, on a level track, $A\,B$. Then (the speed being uniform), we have, **on A B, T = F**; or t ($= T - F$) $=$ zero (¶ 18); and ($A\,B$ being level), we have: gravity component, F_s, $=$ zero; and tractiv force, T ($= F$) $= F_r + F_s = F_r + 0 =$ the nongravitational resistance, F_r

25. At B, let this train encounter an up-grade, $B\,C$; and let

θ = the angle, $C\,B\,D$, between the grade, $B\,C$, and the horizontal;
t = $T - F$ = net tractiv force
  = loco tractiv force minus total or resultant resistance;
W = weight of train and locomotiv;
F_s = $W \sin\theta$ = the gravity component;
g = gravity acceleration = 32.2 ft per sec per sec;
v = train velocity at B.

26. Now, if, **on the grade, B C** (in spite of the addition of F_s to the resistance) T is so maintaind that we have

T > F (virtual grade, $b\,d$, *diverging* from actual grade, $B\,C$),

then (see ¶ 18) the vel is accelerated, and accel $=$ $g\,t/W$.
If

T $=$ **F**, t $=$ 0 (virtual grade, $b\,c$, *parallel* with actual grade, $B\,C$), then the vel is uniform (accel $= g\,t/W =$ zero). In either of these cases, the train ascends the grade indefinitly.

27. But if, on the grade, $B\,C$, we have

T $<$ **F** (virtual grade, $b\,c$, $b\,c'$ or $b\,c''$, and actual grade, $B\,C$, *converging*),
then the vel is retarded, with negativ accel $= -\, g\,t/W$, and the unbalanced retarding force, $-\,t = T - F$, brings the train to rest
in a height, h_c, h_c' or h_c'', and
in a dist, $h_c/\sin\theta$, $h_c'/\sin\theta$, or $h_c''/\sin\theta$.
determined as follows:—

28. (1) If, on the grade, $B\,C$, we have

T ($<$ **F**) $=$ $\mathbf{F}_r$ (virtual grade, $b\,c$, *horizontal*),
then the train (see ¶ 14) moves under the action of the gravity component, $t = F_s = W\sin\theta$, alone, with neg accel $= -\,g\,t/W = -\,g\,W\sin\theta/W = -\,g\sin\theta$. Hence, the unbalanced retarding force, $-\,t = F_s = W\sin\theta$, brings the train to rest
in a height, h_c $=$ $v^2/2g$, and
in a dist, $B\,c$ $=$ $h_c/\sin\theta$.

29. (2) But if, on the grade, $B\,C$, we have either
(a) **T** ($<$ **F**) $>$ $\mathbf{F}_r$ (virtual grade, $b\,c'$, *ascending*), or
(b) **T** ($<$ **F**) $<$ $\mathbf{F}_r$ (" " $b\,c''$, *descending*) ;
then the unbalanced retarding force, $-\,t = T - F$ will bring the train to rest

in a height, (a) $h_c' = h_c\,W\sin\theta/t'$, or
(b) $h_c'' = h_c\,W\sin\theta/t''$;
in a dist, (a) $B\,c' = h_c\,W/t' = h'_c/\sin\theta$; or
(b) $B\,c'' = h_c\,W/t'' = h_c''/\sin\theta$.

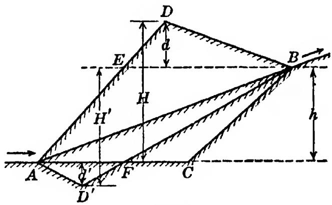

Fig. ?.

Work due to elevation differences.

30. Fig 3. Theory. In moving a train, of weight, W, from A to B (whether thru the uniform grade, $A-B$, or via $A-C-B$, or via $A-D-B$, or via $A-D'-B$), the net or resultant work done, due to elevation diff, alone, and neglecting friction, is theoretically $W\,h$, or the work of lifting the wt, W, thru the vert height, h.

31. In traversing $A-B$, or $A-C-B$, the train does not rise above B, or descend below A; and the *total* work, due to elev diff, is equal to the *net* or *resultant* work, $W\,h$.

32. In traversing $A-D-B$ or $A-D'-B$, the train wt, W, must indeed be lifted thru the greater height, H or H', respectivly, making the *total* work, due to elevation diff, $=$ $W\,H$, or $W\,H'$, respectivly; but, theoretically, the additional work, $W\,d$ or $W\,d'$, entaild by the lift, $d = H - h$, or $d' = H' - h$, respectivly, is compensated by that given out by the train on the down-grade, after passing the summit, D, or before reaching the lowest point, D'.

33. Practice. Hence, the resultant work, due to elevation diff, remains, mechanically, $= W h$; and this is frequently realized, more or less approximately, in practice; the energy, due to the down grades, being utilized to an extent depending upon the lengths and steepnesses of the grades, and the resistances upon them, and depending also upon the grade beyond *B*, and upon whether a stop is made at *B*, or at the foot (*D'*) of the down grade.

34. Any rise, *E—D* (or fall, *A—D'*), which entails work in excess of *W h*, is accompanied by a fall, *D—B* (or rise, *D'—F*) of equal vert height. But the "rise-and-fall", in *E—D—B* (*A—D'—F*) is *d* (*d'*); and not 2 *d* (2 *d'*).

Practical Considerations.

35. Grades increase the operation cost.
On an up-grade, *A B* or *C B*, Fig 3, p 1075, the lift, *h*, involvs additional fuel cost. Speed reduction, on the grade, may diminish the total normal resistance (compare Fig 1 of Train Resistance, p 1058); but reduced speed means time-loss and therefore increast labor cost.

36. Descending grades. In descending any grade, there may be a reduction of expense for fuel over that required for running on a level, and some reduction in wages cost due to traversing a given dist in less time, but steep down grades are nevertheless troublesome and expensiv, as in wear of brake-shoes and of wheel-treads.

37. Effect of grade length upon tractive force. Upon a long up-grade, unless speed is reduced, any *surplus* boiler pressure, with which the locomotiv may have enterd the grade, is drawn upon and may be exhausted, within a dist depending upon the load and upon the steepness of the grade. Thereafter, the tractiv force is limited by the steaming qualities of the boiler; and it is to be expected that the mean tractive force, on the entire grade, will diminish as the length of the grade increases. Comparing various cases, Mr. Beverley S. Randolph finds, approx:

Length of continuous up-grade, miles:	0	5	10	15	20 and over	
Mean tractiv force =	31	24	19	17	16	% of wt on drivers.

The *steepness* seems not to affect these figures appreciably. Am Soc C E, Trans Vol 70, Dec 1910, p 323.

38. Humps and sags. Notwithstanding the foregoing, minor grades (even tho steeper than ruling grade) may often be properly introduced in the profile of a railroad. Their introduction may effect great economy in construction, thru the avoidance of heavy cutting and filling. For "ruling grade," see ¶ 11, p 1084.

39. An acceleration grade is a hump introduced for the purpose of aiding in stopping and starting trains at a station placed at the grade summit, or to accelerate or retard their speed at a given point. Such grades may reduce not only the wear and tear on wheel-treads and on brake-shoes, in slowing down, and the work required in regaining speed, but the time required in both operations. They are largely used on rapid transit lines, even where their use involves increast excavation for subways, or increast climbing, by passengers, to elevated stations.

40. A momentum grade is one which, however steep, is so short that any train, with reasonable velocity, may surmount it without losing too much of its speed. It is usually so steep that a train could not surmount it without "taking a run", or re-start if stalled upon it.

41. Momentum grades must therefore be introduced only after considering every probable or possible condition which might lead to stalling; such as grade crossings, curvature, sidings, water tanks, stations, etc, on, or just before reaching, the grade; or the possible future installation of such features. If the danger of stalling is slight; or if a train, when stalled, can readily be backt off, and run on again, and if the delay to following traffic is not serious; a momentum grade is permissible.

42. Up-grade limitations. *Starting up-hill.* Where trains must be started up-hill, the grade should be such (Webb) as to permit an acceleration of at least 15 mi/hr in 1000 ft, or a ruling grade should be reduced (Alaska Central Ry) by 0.2 ft per 100 ft.

43. *In cuts,* even where other conditions would permit the use of a level grade, it is usual to establish a grade of not less than 0.2 ft per 100 ft, for the sake of drainage.

44. One *railroad specifies* that, on *sidings*, no grade shall exceed 5% (264 ft per mile) on a tangent, or 3% (158.4 ft per mile) on a curv, or 1% (52.8 ft per mile) where cars are to be loaded.

45. Down-grade limitations. The speed, acquired on a down grade, depends partly upon its vert depth, and partly upon the grade rate. See Classification of grades, p 1087, ¶ 37. The drop should never be such that freight trains (left to themselvs) will attain speeds exceeding say 30 to 35 mi/hr; nor should it reduce the speed of ascending freight trains below 10 mi/hr.

46. Vertical curvs should be employd wherever there is any markt grade change. They prevent forward and backward impacts, due to taking up and giving out slack of couplings betw cars, and avoid the resulting danger of breaking the train in two.

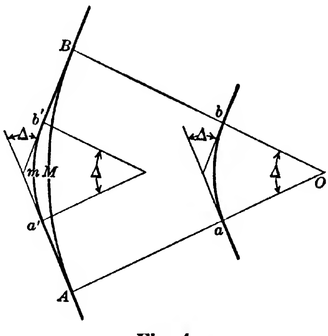

Fig. 4.

CURVS

47. In Fig 4, assuming curv resistance proportional to sharpness, D, or approx inversely as radius, R (See Train Resistance, p 1062, pgf 40); let

	For curv $A\,M\,B$	For curv $a\,b$
n = ...	R/r	R/r
Sharpness = approx.......	$d = D/n$	$D = n\,d$
Radius = ...	$R = n\,r$	$r = R/n$
Curv resistance = approx..	$f_c = F_c/n$	$F_c = n\,f_c$
Curv length, in 100-ft chains.	$L = n\,l$	$l = L/n$

Sweep = ... $\Delta = L\,d = n\,l \cdot D/n = l\,D$

48. Energy. Then, for the energy, E_c, expended (= work done) in balancing curv resistance alone, thru either of these two curvs of equal sweep, Δ, we have:—

$$E_c = F_c\,l = n\,f_c\,L/n = f_c\,L.$$

In other words, the curvature work is the same in both cases; and, plainly, if either of these curvs were shortend or lengthend, its sweep, Δ, and the curvature work required, would be proportionately affected.

49. Work proportional to sweep. Hence, assuming (as above) $F_c = n f_c$, we find that the work, due to curvature alone, on *any* curv, is proportional to its sweep, Δ, and is independent of its sharpness, D, or radius, R.

50. But, comparing the two lines, $A\ M\ B$ and $A\ m\ B$ of equal sweep, (the latter including the tangents, $A\ a'$ and $b'\ B$), we have: length $A\ m\ B$ > length $A\ M\ B$; and hence non-curvature work on $A\ m\ B$ > that on $A\ M\ B$; and, as we have seen (¶ 49), the *curvature* work is *equal* on the two lines of equal sweep, Δ. Hence, *total* work on $A\ m\ B$ (= noncurv work on $A\ m\ B$ + curv work on $a'\ m\ b'$) > *total* work on $A\ M\ B$.

Grade Compensation for Curvature.

51. On account of the added resistance, due to curvature, it is customary (where practicable) to reduce or flatten up-grades upon which curvature occurs, in order that their *total* resistance (grade + curv) shall not exceed that of a *tangent* on the original grade.

52. The compensation rate (grade-reduction rate) is the grade reduction for each degree of sharpness, D. Thus, "0.04" means a grade reduction of 0.04 per cent of grade for each degree of sharpness, D; so that, for a 5° curv, with 0.04 compensation, on a grade of 0.7 per cent, we should have.—

compensated or reduced grade

$$= 0.7\% - (0.04 \times 5)\%$$
$$= 0.7\% - 0.2\% = 0.5\%$$

53. Limiting grades (see p 1084, ¶ 11) should always be compensated, if possible; since the limiting grade, on a *tangent*, offers the maximum resistance which the standard locomotiv is expected to overcome; and any *added* resistance (as from curvature) would therefore endanger the stalling of each train.

54. Non-limiting grades (see p 1084, ¶¶ 12-14) need not be compensated beyond an extent which renders the compensated grade equivalent to the limiting grade. In many cases, this will require no compensation on non-limiting grades; but, on any non-compensated grade, the presence of the curv involvs a cost increase, due either to speed reduction or to increase of fuel expenditure. Compensation is therefore always desirable, even where not actually necessary

55. Compensation, carried to such an extent that it results in a *down*-grade, is unfavorable to traffic in the opposit direction, but this consideration is not necessarily prohibitory. Thus, the return traffic may be light. as where coal or ore cars return empty.

Practice.

56. Rate. Some authorities consider a compensation rate of 0.03 per cent, per degree of sharpness, excessiv, while others consider 0.04 insufficient. The mean of these, = 0.035, is quite generally accepted as a fair average, with modifications, as noted below, for special conditions.

57. Differences in track condition, including tightness of gage, and superelevation, apparently account for much of the diff in practice.

58. Higher rate. Factors tending to increase the rate of compensation are:—the predominance of heavy, low-speed freight trains; the probability of trains being required to slow down or even to stop and stand for some time on the curv; the existence of a stopping place immediately *before* a curv, in which case compensation as high as 0.10 per cent of grade per degree of sharpness has been recommended (Webb); probable dampness in tunnels, etc.

59. Lower rate. On the other hand, lower rates of compensation may be used where high-speed passenger trains predominate; and where there is a regular stopping place immediately *beyond* the curv, in which case the curv resistce may be utilized, along with the full grade, to assist in stopping the train.

60. Change of Rate. Some authorities suggest that the compensation rate should diminish as the sharpness increases; while others hold that the compensation rate should be proportional to the sharpness.

Maximum Sharpness

61. Theoretically, the max permissible sharpness is that which, at max permitted speed, requires the max permitted superelevation.

62. In Fig 5, the eight lower diagrams show the max permissible sharpnesses for diff speeds, and for superelevations of from 1 to 8 inches, on standard gage = 4 ft, 8.5 ins, according to equation 118, Curvs, Superelevation, p 964, ¶ 176; E, ins, $= V^2D/1458.6$, whence $D = 1458.6\ E/V^2$. The upper diagram givs the sharpnesses required by Mr. A. M. Wellington's proposed rule (Ry Location, p 270; Am Ry Eng & M W Assn, Procs, 1910, Vol II, Part I, p 681.) Centrif force $\not>$ Weight/4.

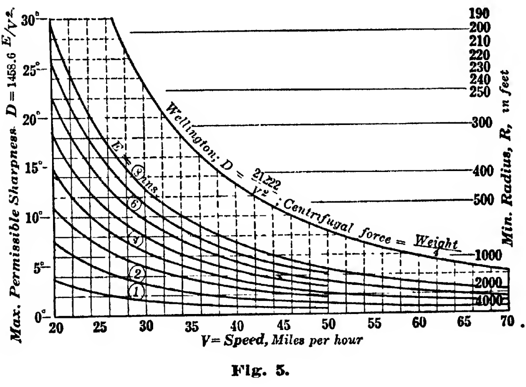

Fig. 5.

63. Practically, max sharpness is governd also by the character of the country and by the traffic. Camp ("Track," p 257) mentions the following as indicating current practice for standard-gage main-track service:—

D	R, ft	
> 4°	< 1433	considered sharp;
10°	574	" very sharp;
15°	383.1	practical limit for full speed;
20°	287.9	used, on compulsion, with speed reduction;
22°	262.0	used, on compulsion, with speed reduction.
We add		
12°	478.3	standard max sharpness (with spirals) **Alaska** Centl Ry, 1909;
14°	410.3	standard max sharpness (with spirals) **N Pac** Ry, 1903.

Curvs as sharp as 67° (90 ft radius) have been used on the elevated railways of New York City.

64. For sidings, *the following* sharpnesses are in use:—

D	*R, ft*	
17°	338	where large road locos must place cars on sidings;
29°	200	for coupled furniture cars;
39°	150	for coupled coal cars and for box cars pusht by 4-wheel or 6-wheel shifting locos;
95°	60	for cars drawn by horses or by short shifting locos on warehouse sidings, etc, with very low speeds.

65. Gard rails are commonly used with curvs of 16° sharpness (R = 359.3 ft) and sharper.

Minimum Sharpness, etc

66. It is sometimes specified that sharpness shall *not* ordinarily be *less* than 1° ($R = 5730$ ft) except where sweep, Δ, $< 3°$; that **curv length** shall be $\nless$ 300 ft; and that a **tangent,** $\nless$ 500 ft long, shall be used betw two curvs in the *same* direction, and a tangent, $\nless$ 600 ft long; betw two curvs in *opp* directions.

See also Gard rails, ¶ 65; Gage on curvs, p 811; Superelevation, p 963.

TRAIN OPERATION COST

GENERAL

1. **The design** and construction of a railroad and of its rolling stock (like its profitableness) depend largely (1) upon the amount and character of the traffic to be expected, (2) upon the resulting revenue, (3) upon the funds available for construction, and (4) upon the expenses (fixt charges plus operation cost). The first three items are usually estimated by the promoters; but the estimation of the construction and operation costs devolvs largely upon the engineer.

2. **The construction and operation costs** depend largely upon
(1) the topography,
(2) the availability of the necessary supplies of material and labor,
(3) the character and amount of the expected traffic,
(4) the character and amount of the proposed rolling stock, (motiv power and cars),
(5) the amount of money available for construction.

3. **The Problem.** Informed as to these features, the engineer is concernd chiefly with fitting, to the topography of the country, that line which best meets the requirements, the final criterion (from the investors' standpoint) being the rate of return upon the money invested.

4. **The comparison between two proposed lines,** *A* and *B*, may be based either (1) upon their respectiv construction costs, plus the capitalized values of their respectiv operation costs; or (2) upon their respectiv operation costs, plus the annual values of their respectiv construction costs. Thus, we may suppose a case where the costs per mile of the two lines, *A* and *B*, compare as follows:—(capitalization at 6%)

	(1) Capitalized		(2) Annual	
	A, $	*B*, $	*A*, $	*B*, $
Construction	25,000	20,000	1,500	1,200
Operation	100,000	125,000	6,000	7,500
Total	125,000	145,000	7,500	8,700

In this supposed case, for a given revenue, line *A* is preferable, notwithstanding its greater construction cost. For Railway Construction Cost Estimates, see p 1094.

TRAIN-MILE, AND TRAIN-MILE COST

5. **The train-mile, "t-m".** When a train (of any length, weight and character) is run (under any conditions) thru one mile, the result is a train-mile (t-m).

6. **Train-mile cost, m.** For any given series of operations (as for the operations of any one line for a day, or for all the railroad operations of a country for a year) the average **t-m cost** is

$$m = \frac{\text{total operation cost}}{\text{number of t-ms run}}$$

Similarly, the t-m cost, due to any given item or items of operation, is

$$\frac{\text{operation cost due to said item or items}}{\text{number of t-ms run}}.$$

7. Average T-m Cost in U. S. From the 24th Annual Report of the Interstate Commerce Commission, see Table 1, below, we have, as the av total t-m cost, for the three classes of lines considerd, for 1911:—

Class		Gross annual operation cost	E = total annual operation cost (Statement 41)	T = total annual train-miles run (Statement 36, p 49)	$m = E/T$ = t-m cost
I	≮	$1,000,000	$1,844,065,958	1,185,632,129	$1.555
II	< >	$1,000,000 $ 100,000	$ 57,092,361	42,315,853	$1 349
III	≯	$ 100,000	$ 13,472,094	9,552,156	$1.410
Totals and average			$1,914,630,413	1,237,500,138	$1 547

The I. C. C. reports for 1890-9 gave values of m ranging only from $0.918 to $0.984 ; avge $0.952

In our subsequent discussions, we assume m = $1.50

8. Departures. The train-mile (t-m) cost, m, varies widely, not only (from time to time), with fluctuation of unit costs, but (at a given time), as betw diff lines. See ¶ 7. Nevertheless, with given unit costs, the t-m cost, on a given line, is practically constant, because the work, required to move a train over the line, is fixt, within narrow limits, by the fact that economy forbids the use of less than the max practical train-load, and this is determined by the character of the line. See ¶ 10.

Train-mile-cost distribution.

9. Table 1 gives the percentages of the t-m cost, assignable to the diff items making up that cost, as determined by the Interstate Commerce Commission. Estimates of these percentages vary widely; but the percentages, given in Table 1, represent the av of American practice, and thus form a useful gide, subject to modification in cases where special conditions cause notable departures from normal conditions.

Operation Cost

Table 1

Deduced from the 24th Annual Report of the Interstate Commerce Commission (for the year ended June 30, 1911) on the Statistics of Railways in the United States; issued by the Government Printing Office, Washington, 1913.

Railroads of	Class I *		Class II *	Class III *

COMPARISON OF LINES

Limiting and Non-Limiting Factors

10. In comparing alternative lines, the factors to be considerd, as chiefly affecting operation costs, are *diffs in grade*, in *curvature* and in *length*. Taken collectivly, and considerd with regard to their effect upon operation cost, grades and curvs fall into two main classes, which must be carefully distinguisht, viz.—limiting and non-limiting, or ruling and non-ruling, or "major" and "minor", grades and curvs.

11. The ruling or limiting grade or curv, or limiting combination of grade and curvature, on a given loco division, is that which affects operation cost by *limiting the length and weight of train* which, under normal working conditions and without "momentum", one standard loco can take over the division, and by thus *limiting the minimum number of trains* (and thus the minimum *work*) required for a given traffic.

12. Total Work. With given motiv power, the *maximum train-weight,* which can be hauld over a given line (while practically independent of the *length* of the line) is thus determind by some limiting or controlling (or *"major"*) condition of grade or of curvature, or of both combined; but the total work required, to haul this max train-wt over the line, may be affected by non-limiting or "minor" conditions as to length, as well as by those of grade and curvature.

13. Thus, suppose that, with a given locomotiv, a long 12° curv (unavoidable on each of two alternativ lines, *A* and *B*) renders 500 tons the max train-wt which can be hauled over either line. Then that curv is a limiting or "major" factor. But, if line *B* has also one or more 4° curvs, or short grades, which are absent from line *A*, or if line *B* is longer than line *A* (the two lines being otherwise similar), then line *B* requires more work than does line *A* to haul the given 500-ton train over the road; and this excess of work givs line *B* the higher operation cost.

14. We thus have:—

	Affecting	Not affecting
Grades and curvs		
Limiting	max train-weight	work on max train
Non-limiting	work on max train	max train-weight
Length differences..........	" " "	" " "
Pusher grades.............	" " "	" " "

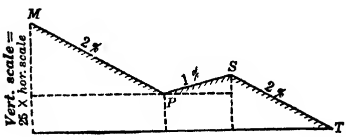

Fig. 1.

15. Steepest vs Limiting Grade. The *limiting* grade is not necessarily the *steepest* grade on the division. Thus:—

(1) A short grade, steeper than the ruling grade, may be surmounted by the standard train and loco, by means of "momentum" (See ¶ 40, p 1076).

(2) Fig 1. Where, for instance, loaded cars move from *M* to *T*, while they return empty from *T* to *M*, the *lighter and shorter* grade, *P S*, opposed to the *heavier traffic*, may be the ruling or limiting grade.

(3) The limiting condition may be a combination of moderate grade with heavy curvature.

16. Sharpest vs Limiting Curv. Similarly, the limiting curv, on a division, may be a long and comparativly easy one. Again; the limiting effect of a given curv may be eliminated by grade reduction. See p 1078, ¶ 51, etc.

For analysis of effect of limiting grades and curvs upon operation cost see ¶¶ 19 to 24.

17. Non-limiting factors are:—

(1) Length-differences;
(2) Pusher grades;
(3) Non-limiting $\begin{cases}\text{grades}\\ \text{curvs}\end{cases}$

Computation

Method of Procedure

18. In comparing the operation costs of two lines, as affected by limiting or non-limiting diffs in grades, in curvature or in length, we determin or estimate (compare Table 2):

1 The normal train-mile ("t-m") cost of each operation item;

2 The percentage, a, which each of these item costs forms of the total t-m cost, m (see Tables 1 and 2);

3. The extent (percentage, b, of a) to which the cost of each item is affected by the grade-diff, curvature-diff, or length-diff in question;

4. The resulting change ($a' = b\,a$, percentage of m) in the percentage value, a, of each item, due to the diff in question;

5 The sum, A', of the values of a', obtaind under "4"; *i. e.*, the total t-m cost of the diff in question, exprest as a percentage of the total normal t-m cost, m;

6. $m' = A'\,m$ = the t-m cost of the diff in question, exprest in dollars;

7. C_a = the annual cost of the diff in question; ¶ 43.
8. V_c = the capitalized value of the diff in question.

Example of Method

Construction of first column ("Add'l train") of Table 2.

Limiting Factors.

19. Example. Under Maint of Way & Structrs, let

t = normal number of daily round trips;	t' = number of add'l daily round trips;
m_s = supt t-m cost of normal trips, t;	m_s' = supt t-m cost of add'l trips, t';
$a_s = 100\,m_s/m$	$a_s' = 100\,m_s'/m$
= m_s as percentage of m;	= m_s' as percentage of m;
S = normal total daily supt cost;	s = increase in S, due to add'l train;

L = line length, in miles.

Let it be supposed that, with a given alinement and profile, 10 round trips per day ($t = 10$) are required to handle a given traffic, and that a proposed increase of grade or curvature, or both, due to a proposed change of line, would so reduce the max train-wt as to require 11, instead of 10, daily round trips for the same traffic. Then

$$t' = 11 - 10 = 1; \quad \text{and } t'/t = 1/10.$$

20. To find b. Let it be found or assumed that this increase of 1/10, in t, increases the total superintendence cost, S, (first item of Table 2) by only 1/100 or 1%.

Then

$$\frac{s}{S} = \frac{L\,t'\,m_s'}{L\,t\,m_s} = \frac{t'}{t} \times \frac{m_s'}{m_s} = \frac{1}{100}; \quad \text{and, (¶ 18, 4)}$$

$$b_s = \frac{a_s'}{a_s} = \frac{m_s'}{m_s} = \frac{s}{S} \times \frac{t}{t'} = \frac{1}{100} \times \frac{10}{1} = \frac{1}{10} = 10\%;$$

or, in this example, the t-m cost, m_s', of supt, for the additional train, is 10% of the normal supt t-m cost, m_s.

21. Effect on the other cost items. Then, averaging values of a for the three classes of road in Table 1, ¶ 9, using round figures for convenience, and applying assumed percentages, b (subject, of course, to wide variations under diff conditions), to the remaining items of operation cost, we obtain (merely by way of illustration of the method), the remaining values of a' ($=$ $b\,a$) given under "Add'l train" in Table 2.

22. Summing these values of a', we obtain A', $=$ 43.8, as the t-m cost of the add'l train, exprest as a percentage of the total normal t-m cost, m. Then

$$m' = A'm,$$

where m $=$ the total normal t-m cost, here assumed at \$1.50.

23. In this case, therefore, we have, as the t-m cost of the additional train required by the limiting factors,

$$m' = A'm = 0.438 \times \$1.50 = \$0.657.$$

24. To m', thus found, should be added a small amount (say from 1 to 1.5 cents) to cover interest on cost of each additional loco and tender required.

Other (non-limiting) factors.

25. In its remaining columns, Table 2 givs similar analyses for the remaining (non-limiting) operation-cost factors: viz.—length, pusher grades, rise-and-fall, and curvature. See below.

26. Length-difference. With a given max train-weight (determind by the limiting grade or curvature or both), a length-increase increases operation cost by entailing additional work on *each train, viz.—the work of hauling the max train-wt over the additional length.*

27. *Great and small length-differences.* On any length-diff (great or small), roadway and track maint cost per t-m will approx equal the normal cost of that item; but train-wages cost per t-m (which, on a great length-diff, may also equal the normal), are negligible on small length-diffs The effect of this upon the estimate may be illustrated by a supposed case, as follows; in which, assuming (for convenience) that roadway and track maint amounts normally to 15%, and train wages to 13% (compare Table 1) of the total operation cost, we assume probable values of b, find the resulting values of a', and thus compare the effects of great and of small length-diffs as affecting the sum of the costs of these two items alone.

	Normal. On entire line	On a great length-diff		On a small length-diff	
	a % of m	b % of a	a' % of m	b % of a	a' % of m
Roadway & track maint.	15	100	15	100	15
Train wages	13	100	13	0	0
% of total t-m cost, m, for these 2 items only,	28		28		15

28. Length diffs are sometimes *classified* as follows:—

	Length-difference Class		
	A	B	C
Train wages	*Not affected*	**Affected**	**Affected**
Number of stations or of sidings	*Not affected*	*Not affected*	**Affected**

The effects of length-diffs upon operation cost are indicated in Table 2.

29. *Effect of length-difference upon revenue.* Of two competing roads, betw two given points, either will lose thru business if it charges higher thru rates than the other. Hence, under competition, the rates, on both lines, betw two given points, are usually (other things equal) those proper to the shorter line, and shortness is therefore an important advantage; since the shorter line has the less operation cost.

30. But, in the absence of competition, freight and passenger rates are usually based upon the distance traveld; and the revenue of a line, betw two given points, is therefore practically proportional to length of line; whereas total operation cost usually increases less rapidly than does length of line. Hence, in the absence of competition, the longer line is in general the more remunerativ.

31. A pusher grade is a grade so steep, and so long, as to require regularly two locos or three locos (instead of one) for each train ascending it. Hence, where the pusher locos are of equal power with the road locos, the pusher grade is usually made about twice, or about three times, as steep as the limiting grade on the division, according to whether each ascending train requires two locos or three locos.

32. Theoretically, therefore, the first loco supplies, and each pusher supplies, only the power necessary to haul the max train up the limiting grade; and the work, required of each pusher outfit, is theoretically only that of hauling the max train up *an additional stretch* (= pusher-grade length) of the limiting grade.

For analysis of operation cost of pusher grades, see Table 2.

33. See Table 2. *Pusher grades affect* chiefly the items of
Roadway and track maintenance,
Repairs and renewals of locos, cars, etc,
Loco fuel and expenses.

34. The annual operation cost of a *pusher loco and tender* ranges ordinarily between $7,500 and $18,000, with $10,000 to $15,000 as more probable limits.

35. A non-limiting or minor grade is either less steep than the limiting grade (p 1084, ¶ 11), or so short that it can be surmounted, by "Momentum" (p 1076, ¶ 40), by one standard loco drawing the max train. It therefore affects operation cost by requiring additional work to lift the max train. Problems relating to non-limiting grades are usually called "rise-and-fall" problems.

A comparison of the definitions of s_e, h_d, h_e and L_s, ¶¶ 39 and 43, will show that the additional work, entaild by a minor grade, is equated with that of hauling the max train over *an additional stretch* of level track, whose length is such that the work of this level hauling, over it, is equal to that of lifting the train weight thru the vertical height of the grade.

For analysis of non-limiting grade problems, see p 1088, ¶ 39.

36. Similarly, a non-limiting or minor curv is either less sharp than the limiting curv, or so short that one standard loco can traverse it with the max train. It affects operation cost by adding to the resistance which the loco, drawing the max train, must overcome. It thus increases the work required in moving the max train over the line.

A comparison of the definitions of D_e, Δ_d, Δ_e and L_c, ¶¶ 39 and 43, will show that the additional work, entaild by a curv, is equated with that of hauling the max train over *an additional stretch* of straight track, whose length is such that the work of this hauling, over it, is equal to that due to the curvature.

For analysis of minor curv problems, see ¶ 39.

37. Classification of non-limiting grades. Fig 2, p 1091. According to the behavior of descending trains, non-limiting grades are classified as in the tabulation on p 1088, illustrated by Fig 2, p 1091. Compare J. B. Berry, Am Ry Eng & M W Assn, Bulletin 49, March 1904, p 21; and A. M. Wellington, R. R. Location, pp 330 and 374, and Table 122, pp 372-3.

	Grade Class. See Fig 2, p 1091.		
	A	B	C
Drop	$\ngtr$ 30 ft	> 30 ft; but $\ngtr$ drop indicated by solid curv	> drop indicated by solid curv
Remarks	Effect negligible	Will not overtax up-bound locos	Up-bound locos must use sand

Ordinarily an initial speed of 10 m/h will not reach 30 m/h if

	A	B	C
Steam is	on	off	off
Brakes are	releast	releast	applied

38. On a 0.6% grade, the longitudinal gravity effect about equals the train resistance at 32 mi/hr. Hence, without steam and without brakes, that speed will not ordinarily be exceeded, on such a grade or on lighter grades, however long the grade, or however great the drop.

39. Effect of non-limiting grades and curvs upon operation cost.

Let

s_e = that grade, in ft per 100 ft*	D_e = that curv sharpness, in degrees of sweep per 100-ft chain¶§

which produces an additional resistance, due to

grade alone	curvature alone

equal to the normal resistance, f_n (see p 1057) on a level tangent.

Then, for the *work* done on a given train, in balancing this additional resistance alone, we have

on a mile (5280 ft) of s_e grade, work = a train-lift of 52.8 s_e ft, on any grade;*	on a mile (5280 ft) of D_e° curv, work = that of balancing curv resist alone, thru 52.8 D_e° of sweep, § of any sharpness.

and this is equal also to the work of balancing the normal resistance, f_n, thru a mile of level tangent. But the *cost* of the work, required for

a train-lift of 52.8 s_e feet	balancing curv resistance alone thru 52.8 D_e° of sweep

is much *less* than the normal *cost*, *m* (say $1.50; see ¶ 7), of a train-mile on a level tangent; because (continued on p 1089)

*s_e is commonly taken at 0.5% = 26.4 ft per mile; or 52.8 s_e = 26.4 ft lift.

†Insted of 60% and 65%, Mr. Berry (Am Ry Eng & M W Assn, Bulletin 49, March 1904, p 22) takes 25% and 45% respectivly. The diff shows how largely such estimates depend upon individual judgment.

¶D_e is commonly taken at 10°; or 52.8 D_e° = 528° of sweep.

§Let f_1 = curv resistce on a 1° curv.
Then $D_e = f_n/f_1$.
f_n is usually assumed to range from 5 to 10 lbs, and f_1 from 0.5 to 1.5 lb, per ton of 2000 lbs.

(1) the *expenditure* of energy, in the work of train-*lift*, is often compensated (at least in part) by a *gain* of energy on the corresponding *fall;* and

(2) the normal train-mile cost, *m*, includes items which are not directly affected by train-lift or by curvature. Thus:—

Except for the item of fuel, the effect of train-lift upon operation cost is practically negligible. Of the total loco fuel cost (= say 10% of the total normal t-m cost, *m;* see Table 1), a large proportion, averaging say 45%, is due to loss in firing, in standing, stopping and starting, and in overcoming curv and grade resistce, leaving only 55% as the cost of hauling on a level tan, which work, in a mile, is equal to that reqd for 52.8 s_e ft of train-lift. To this 55% Prof. Webb adds, for Classes B and C (see ¶ 37) 5% for fuel on down grades; and, for Class C, another 5% for loss thru braking; making the average total, b = 60% for Class B, and b = 65% for Class C.* Class A grades are neglected as not materially affecting operation cost.

We have, therefore, for all items, (making crude assumptions for expenses other than loco fuel); (see Table 2)

Class B

	a	*b*	*a'*
Fuel	11	60	6.6
General	8	..	1.0
For grades ...	*A'*	=	7.6

$m' = A'm$
$= 0.076 \times \$1.50$
$= \$0.114$

Class C

	a	*b*	*a'*
Fuel	11	65	7.1
General	8	..	2.0
For grades	*A'*	=	9.1

$m' = A'm$
$= 0.091 \times \$1.50$
$= \$0.136$

Curvature affects chiefly the items of roadway and track maintenance, loco and car repairs, and loco fuel.

We assume, (see Table 2)

	a,	*b*,	*a'*,
Roadway & track maint..	16	75	12
Repairs			
loco	7	100	7
cars	8	100	8
Loco fuel	11	50	5.5
General	8	25	2
Curvature,	*A'*	=	34.5

Hence, for curvature,
$m' = A'm$
$= 0.345 \times \$1.50 = \$0.5175$

For roadway and track supt, Mr. J. B. Berry, Am Ry Eng & M W Assn Bulletin 49, March 1904, p 20, givs (instead of our a = 16%) a = 14.76%, obtaind as follows:

	a,	*b*,	*a'*,
Rails	2.28	300	6.84
Ties	3.01	50	1.50
Ballast	0.28	50	0.14
Spikes &c...	0.86	100	0.86
General	8.33	50	4.16
Supt	14.76	91	13.50

*See † foot-note, p 1088.

40. Table 2, at the heads of pp 1090-1. Assumed values for a (% of m), and b (% of a), and deduced values of a' ($= ba$), A' (sum of a') and m' ($= A'm$).

41. Table 2 illustrates the application of the method of ¶18, for finding the modified t-m cost, m', due to each of the several factors affecting operation cost, viz.—

1. Limiting grades and curvs (additional train);
2. Length-differences;
3. Pusher Grades;
4. { Non-limiting grades (rise-and-fall)
   Non-limiting curvs.

42. Caution. The values of b (% of a), here given, represent merely prob avs, and are used to illustrate the method of ¶ 18, rather than to represent reliable percentages. The actual values of b vary widely with diff conditions, with the classif'n of the cost items, and with the judgment of the estimator. See foot-note †, p 1088. They must, in general, be determined or estimated for each case.

---

*For additional trains (first column), J. B. Berry, Am Ry Eng & M W Assn, Bull 49, March '04, p 12, finds A' = 43 29% of m. E. H. McHenry, N. Pac. Ry Rules, pp 12, 16, assumes A' = 60% of m.

†Using other classifn's of length diffs, J. B. Berry, U. P. Ry, A. R. E. M. W. A. Bull 49, Mar '04, and E. H. McHenry, N. P. Ry, '03, adopt values of A' as follows:—

		Class A	Class B	Class C
Berry, U. Pac	A' =	32%	46%	59%
McHenry, N. Pac	A' =	22%	52%	100%

mination of m'.

43. Deduction of annual and capitalized costs. Having thus, in accordance with ¶¶ 18 to 42, estimated the modified train-mile cost, *m'*, as determind by a given factor in a given case; *we proceed, as follows, to deduce, from m', the annual operation cost, C_a, of a given difference (in limiting or in non-limiting conditions) betw two lines, and the capitalized value, V_c, of said annual cost.*

In the following schedule, an "increase" and its effects may be *negativ.*

<table>
<tr><td colspan="2">Let</td></tr>
<tr><td>s_e = that grade, in ft per 100 ft,</td><td>D_e = that sharpness, in degs of sweep per 100-ft chain,</td></tr>
<tr><td colspan="2">which produces an additional resistance equal to the normal resistance, f_n, on a level tangent;</td></tr>
<tr><td>h_d = diff, as to lift, betw two lines;
h_e = 52.8 s_e
= 1 "equivalent grade-mile"
= that lift for which the work reqd is</td><td>Δ_d = diff, as to sweep, betw two lines,
Δ_e = 52.8 D_e°
= 1 "equivalent curv-mile"
= that sweep for which the curv work reqd is</td></tr>
<tr><td colspan="2">equivalent to that of hauling the train thru a mile of level tangent
Then:</td></tr>
<tr><td>$L_s = \frac{h_d}{h_e}$ = the diff, as to rise-and-fall, betw the two lines, exprest in terms of the "equivalent grade-mile", h_e.</td><td>$L_c = \frac{\Delta_d}{\Delta_e}$ = the diff, as to sweep, betw the two lines, exprest in terms of the "equivalent curv-mile", Δ_e.</td></tr>
</table>

C_a = annual cost of a given difference between two lines;
V_c = capitalized value of C_a;
d = the number (usually 365 or 313) of train-days in a year;

<table>
<tr><td>(1)</td><td>(2)</td><td>(3)</td><td>(4)</td><td>(5)</td></tr>
<tr><td>Let t' =</td><td colspan="4">t =</td></tr>
<tr><td>No. of add'l trips. ¶ 11.</td><td colspan="4">number of daily round trips.</td></tr>
<tr><td>Then $d\,t'$ =</td><td colspan="4">$d\,t$ =</td></tr>
<tr><td colspan="5">number of train-miles made over any one mile in one year by</td></tr>
<tr><td>t' trains,</td><td colspan="4">t trains,</td></tr>

<tr><td rowspan="2">length</td><td rowspan="2">pusher-grade length.</td><td colspan="2">number of equivalent</td></tr>
<tr><td>grade miles.</td><td>curv miles.</td></tr>
</table>

(Table continued on page 1093.)

(Table continued from page 1092.)

<table>
<tr><td>(1)</td><td>(2)</td><td>(3)</td><td>(4)</td><td>(5)</td></tr>
<tr><td colspan="5">Then, for a given traffic, an increase in</td></tr>
<tr><td rowspan="2">limiting grades & curvs</td><td rowspan="2">line length</td><td rowspan="2">pusher-grade length.</td><td colspan="2">non-limiting</td></tr>
<tr><td>grades</td><td>curvature</td></tr>
<tr><td colspan="5">increases operation cost by</td></tr>
<tr><td rowspan="2">adding t' to the No. of daily rnd trips on L;</td><td rowspan="2">making each of t trains run L_a mls frthr, each single trip;</td><td rowspan="2">requiring pusher outfit for each single trip on L_p;*</td><td colspan="2">increasing resistance on</td></tr>
<tr><td>grades;</td><td>curvs;</td></tr>
<tr><td colspan="5">thus adding, to the normal work, work equivalent to that required for hauling, daily,</td></tr>
<tr><td>t' trains</td><td colspan="4">t trains</td></tr>
<tr><td colspan="5">over a distance equal to</td></tr>
<tr><td>L.</td><td>L_a.</td><td>L_p.*</td><td>L_s.</td><td>L_c.</td></tr>
<tr><td colspan="5">m' = $A'm$ = train-mile cost of this added work.</td></tr>
<tr><td colspan="5">Number of additional equivalent train-miles per annum, due to diff betw the two lines, =</td></tr>
<tr><td>$d\,t'\,L$.</td><td>$d\,t\,L_a$.</td><td>$d\,t\,L_p$.*</td><td>$d\,t\,L_s$.†</td><td>$d\,t\,L_c$.</td></tr>
<tr><td colspan="5">C_a = additional annual cost, =</td></tr>
<tr><td>$d\,t'\,L\,m'$.</td><td>$d\,t\,L_a\,m'$.</td><td>$d\,t\,L_p\,m'$.*</td><td>$d\,t\,L_s\,m'$.†</td><td>$d\,t\,L_c\,m'$.</td></tr>
<tr><td colspan="5">V_c = C_a ÷ interest rate.</td></tr>
</table>

It will be noticed that, in all five cases, the additional work is either that of train haulage, or is equated to (and stated in terms of) train haulage. In column 1 (difference in limiting conditions) said haulage is that of *additional trips* over *the same length, L*, of track in both cases; whereas, in each of the other four columns, the number of trips is unaffected by the diff betw the two lines compared, and the equivalent haulage is that of said trips (*the same* for both lines) over *an additional length, L_a, L_p, L_s* or *L_c*, of track. See ¶¶ 32, 35 and 36.

*This assumes that a pusher-outfit-mile is equivalent to a train-mile, and that pusher-outfit operation cost is the same in both directions. For any deviation from these assumptions, allowance is to be made in determining the value of b, ¶ 18, (3). See also ¶ 32.

†This assumes equality of total lift, on non-limiting grades, in both directions; and neglects advantage due to down grades.

CONSTRUCTION COST ESTIMATES

INTRODUCTORY

Variations and Limits

1. Elements affecting cost. Railroad construction cost varies between wide limits. It depends largely upon the topography and the geology of the country traverst; upon its value and the resulting right-of-way cost; upon the amount and the cost of land required for yards and terminals; upon the unit costs of the several items of construction; upon the cost of labor; upon the construction methods employd; upon the requirements as to grade and alinement; upon the amount and the character of the traffic to be carried; upon the absence or presence and the nature of competition; and upon the funds available.

2. Initial and ultimate costs. The construction cost of a given railroad, as shown by the Company's accounts, increases with its age; for the original cost (often kept at a minimum by the economic desirability of putting the road in earning condition as soon as possible) may be much less than its total subsequent construction cost ("Original Cost to Date") after desirable improvements have been made. See ¶¶ 4 and 11.

3. On the other hand; constructions, included in the original cost, are often abandoned or superseded; but their cost nevertheless enters into the total construction cost.

4. Accounting. For a given actual construction cost, the available cost *data* are affected by differences in account-keeping method. For instance; items, properly chargeable to construction, are often charged to way maintenance; as where a temporary timber trestle (part of the original construction) is afterward gradually filled in and the necessary train-service is charged to maintenance.

5. In deducting the construction cost of a proposed line from that of an existing line, allowance must of course be made for differences in condition betw the two; and, even with given unit costs, different portions of a given line may have very different costs per mile; and, therefore,

$$\text{the apparent construction cost per mile} = \frac{\text{total cost}}{\text{length}}$$

of one part of a given line, may be much higher, and that of another part much lower, than that of the entire line.

6. Example. Thus; a trunk line, running eastward from the Pacific thru several states, and burdend with heavy real estate costs at its terminals, and with heavy construction cost proper on that portion of its line crossing the mountains, may pass also thru regions of more favorable topography and requiring but little outlay for real estate. In using, for comparison, the construction-cost data of such a line, the character of the proposed road must be kept in mind. If, for instance, the proposed line traverses only favorable and inexpensiv country, and if it requires no expensiv termini; it would be misleading to apply, to it, without modification, construction-cost data covering the entire trunk line, including its more expensiv portions.

7. Tendency to increase. When using early data as a basis for the estimation of present or future costs, bear in mind that the tendency of railroad construction cost, as a whole, is to increase; for the reduction of unit cost, in some particulars, due to improved manufacturing and operating methods and apparatus, is usually more than offset by increase in wts of rolling stock, by increasingly exacting demands on the part of the traveling and shipping public, by increase of traffic, which justifies costly construction for the sake of the reduction of operating expenses, and by increasing insistence, on the part of the community, upon the avoidance of nuisance and of accident.

8. Thus, where grade crossings are still retaind, they are required to be provided with elaborate interlocking and signaling apparatus; but, more often, elimination of grade-crossings is demanded; and the abolition of a grade-crossing may cost $100,000 or more.

9. The range of variation, in total cost, increases also, and for like reasons.

10. Thus, upon a line of moderate length, joining populous centers, the cost of terminals, of modern type, may equal the remaining construction cost; whereas, upon a long line, connecting many small towns or depending chiefly upon mineral or industrial traffic, the cost of terminals may be relativly insignificant.

11. The Interstate Commerce Commission, by Act of Congress, approved 1913, March 1, is instructed to ascertain, respecting each railroad property:—

(1) Its original cost, to date;
(2) Its cost of reproduction, new;
(3) Its cost of reproduction, new, less depreciation.

12. Differences in estimates. As might be expected, there is usually a material difference betw (a) estimates prepared by a railroad company for the purpose of showing a *high* value (as in cases of proposed sale, or where it is desired to justify existing or proposed freight and passenger rates), and (b) estimates prepared by the same company for the purpose of showing a low value, as for purposes of assessment. See ¶ 139.

13. "General Expenditures." In addition to Construction Cost proper, there are the cost items of financiering, negotiation, legal service, insurance, taxes, depreciation, etc, (see III. General Expenditures. ¶ 18) which affect an appraisal of the property in its existing condition; as for purposes of taxation. Such an appraisal may properly consider the earning capacity of the plant, which, of course, may be greatly affected by considerations quite independent of construction cost. For instance, the business conditions of the country traverst may conceivably give high commercial value to a very cheaply constructed road; or, on the other hand, they may become such as to deprive an expensivly constructed road of all value.

14. All that can be usefully attempted here is to give such data (deduced from publisht records) as may facilitate the making of preliminary cost estimates for a projected line, bearing in mind the preceding cautionary suggestions.

15. Unit costs. In estimating railroad construction costs, we are concernd with

(1) unit costs (as per cu yd of grading, per acre of clearing, per lineal ft of tunnel, etc) and

(2) per-mile costs, or costs per mile of line or of single track.

16. Line-mile vs Track-mile. In figuring per-mile cost, distinction must be made between

(1) *line*-mile (or *road*-mile) cost (cost per *line*-mile)

$$= \frac{\text{total cost}}{\text{number of miles of main } \textit{line} \text{ and branch } \textit{lines}}$$

(irrespectiv of the number of tracks and of sidings), and

(2) *track*-mile cost (cost per *track*-mile, *i. e.*, per mile of *track*)

$$= \frac{\text{total cost}}{\text{number of miles of track}}.$$

17. Thus, a double-track road, L miles long, without side-tracks, has L *line*-miles, and 2 L *track*-miles.

In any given case, line-mile cost $\geqq$ *track*-mile cost.

For a given *single*-track line, without branches or sidings, we have :—

line-mile cost = *track*-mile cost.

For a given *double*-track line, without branches or sidings, we have :—

line-mile cost = 2 × *track*-mile cost;

but the *line*-mile cost of a double-track road is (other things equal) *less* than double the *line*-mile cost (= *track*-mile cost) of a single-track road.

I. C. C. Classification

18. Classification of Investment in Road and Equipment of Steam Roads, Prescribed by the Interstate Commerce Commission in accordance with Section 20 of the Act to Regulate Commerce. Issue of 1914. Effectiv on July 1, 1914. (Here condenst.)

General Accounts.

I. Road. "Cost of land, fixt improvements, and roadway machines and tools ownd by the carrier and devoted to transportation service."

II. Equipment. "Cost of the several classes of equipment ownd by the carrier, or held under equipment trust agreements for purchase."

III. General Expenditures. "Expenditures made in connection with the acquisition and construction of original road and equipment, and with extensions, additions and betterments to road and equipment property, when such expenditures cannot properly be included in any of the foregoing accounts as a part of the cost of any specific work."

Primary Accounts.

I. Road.

1. Engineering.

Including "the pay and expenses of engineers, assists. and clerks engaged in the survey and construction of new lines and extensions, or in making additions to and betterments of the carrier's road, including wharvs and docks"

2. Land for Transportation Purposes.

Including "the cost of land of necessary width acquired for roadway; the cost of land for station, office, shop and other grounds; for ingress to or egress from such grounds; for borrow pits, waste banks, snow fences, sand fences, and other railway appurtenances; and for storage of material adjoining the right of way; the cost of land for wharvs and docks and the cost of riparian or water rights necessary therefor; the cost of removing from the right of way and locating elsewhere the property of others, and the cost of the necessary land for relocation of the property, when such costs are assumed by the accounting carrier."

3. Grading.

Including "the cost of clearing and grading the roadway, and of constructing protection of a permanent character for the roadway, tracks, embankments, and cuts."

4. Underground Power Tubes.

5. Tunnels and Subways

Including "the cost of tunnels and subways for the passage of trains, including apparatus for ventilating and lighting, and safety devices therein, other than signals."

6. Bridges, Trestles and Culverts.

Including "the cost of the substructure and superstructure of bridges, trestles, and culverts which carry the tracks of the carrier over watercourses, ravines, public and private highways, and other railways."

7. Elevated Structures.

Including "the cost of elevated structures and foundations of elevated railway systems—structures other than earthwork, which are for the purpose of elevating tracks above the grade of streets, and which are not properly classable as bridges or trestles."

8. Ties.

9. Rails.

10. Other Track Material.

Including anticreepers, bumping posts, railway crossings, derails, guard rails, rail braces, rail joints, tie-plates, spikes, turnouts, etc.

11. Ballast.

12. Track Laying and Surfacing.

13. Right-of-way Fences.

14. Snow and Sand Fences and Snowsheds.

15. Crossings and Signs

Exclusiv of "railways crossing at grade", for which see Account 10.

16. Station and Other Buildings.

17. Roadway Buildings.

18. Water Stations.

19. Fuel Stations

20. Shops and Enginhouses.

21. Grain Elevators.

22. Storage Warehouses.

Including "warehouses in which merchandise is stored and which the railway companies or others operate commercially as storage warehouses."

23. Wharvs and Docks.

24. Coal and Ore Wharvs.

25. Gas Producing Plants.

26. Telegraph and Telephone Lines.

27. Signals and Interlockers.

28. Power Dams, Canals, and Pipe Lines.

29. Power Plant Buildings.

Including "the cost of the buildings of power plants erected to furnish power . . ." See Account 45, p 1098.

30. Power Substation Buildings.

Including "the cost of the buildings of power substations erected to transform power . . ." See Account 46, p 1098.

31. Power Transmission Systems.

Including "the cost of high-tension transmission systems, . . . used for transferring power from producing plants to a place where it is transformd . . ."

32. Power Distribution Systems.

Including "the cost of distribution systems, . . . for conveying low-tension electric power from producing plants or transformer stations and for conveying steam and compress air from producing plants to the place where used . . ."

33. Power Line Poles and Fixtures.

34. Underground Conduits

35. Miscellaneous Structures.

36. Paving.

37. Roadway Machines.
Including boilers, cars (hand-, lever-, motor inspection-, push-, etc), concrete mixers, ditching and dredging machines, portable engins, grading and hydraulic outfits, hydraulic jacks, pile drivers, unloading plows, rail unloaders, rock crushers, steam rollers, etc.

38. Roadway Small Tools

39. Assessments for Public Improvements.

40. Revenues and Operating Expenses During Construction.

41. Cost of Road Purchast

42. Reconstruction of Road Purchast.

43. Other Expenditures—Road.

44. Shop Machinery.

45. Power Plant Machinery.

46. Power Substation Apparatus.

47. Unapplied Construction Material and Supplies.

(Nos 48, 49 and 50 left blank.)

II. Equipment.

51. Steam Locomotivs.

52. Other Locomotivs.

53. Freight-train Cars.

54. Passenger-train Cars.

55. Motor Equipment of Cars.

56. Floating Equipment.

57. Work Equipment.

58. Miscellaneous Equipment.

(Nos 59 to 70, inclusiv, left blank.)

III. General Expenditures.

71. Organization Expenses.

72. General Officers and Clerks.

73. Law.

74. Stationery and Printing.

75. Taxes.

76. Interest during Construction.

77. Other Expenditures—General.

References, etc.

19. Acknowledgment to Gillette's "Cost Data." For most of the information, given in the following paragraphs, on the engineering features of railroad construction cost, we are indebted to Mr. Halbert P. Gillette's monumental "Handbook of Cost Data", (1910-1914, McGraw-Hill Book Co.), which we have very freely used at the author's invitation. In using the material selected, however, we have digested and arranged it to suit the purposes of "TRAUTWINE", and have frequently substituted deductions from Mr. Gillette's figures, in the place of the figures themselves. Owing to differences in methods of classification of construction cost items we have frequently been obliged to rely upon assumption for the proportions of a given reported item chargeable to this or to that "account" of the Interstate Commerce Commission, Classification of 1914 (¶18).

20. Caution. We repeat that all of our data, on railroad construction cost, are intended, not as business quotations, but merely as indicating the *range* within which the cost of a given item, or the cost per mile, may reasonably be expected to fluctuate.

21. List of References. The following are the principal statements respecting steam railroads, in Mr. Gillette's "Cost Data", to which reference is made in the text below. There, as here, the reference is indicated by the folio number, prefixt by the letter "G". Thus, "G 1418" means "See Gillette's 'Cost Data', page 1418".

	Miles of line	Miles of track
G 1289. Winchester & Beattyville R R, Kentucky. Built, 1893, in rugged country, to open up a mining district. Max grade, 1%; max curv sharpness, 6°, except for two 12° curvs. Labor, $1.25 per day. John H. Pearson, Eng. News, 1893, Sep 14, p 209.	8	8
G 1290. A logging railroad in northwestern Penna, built 1890. Ruling grade, 3.3%. Max curv sharpness, 18°. Country very rough and heavily wooded. Wages, $1.25 ? per 10-hour day. Costs given refer to the heaviest part of the line.	7	
G 1291. Texas. First-class branch line of St. Louis Southwestern Ry. Ridge line, nearly all tangent. Built, 1903.	12.13	13.7
G 1303. Great Northern in Washn. Original cost. Built by contract, at reasonable prices, in 1891-4. Crosses rugged mountain range. Cascade tunnel cost over $2,500,000.	488	527
G 1306. Fairhaven Southn branch. Easy country.	32.3	
G 1307. Spokane Falls & Northn branch, about 1890.	130.5	151.3
G 1308. Washn & Great Northn branch. 1906. Mountainous country.	83.9	91.8
G 1310. Great Northn in Washn. Original cost plus improvements to 1906.	768.0	954.8
G 1319. Great Northn in Washn. Reproduction estimate, 1906.	768.0	954.8
G 1321. Northn Pac in Washn. Original cost plus improvements to 1906. Built about 1880. Difficult and costly explorations. Built largely by company forces.	1645	2205
G 1329. Northn Pac in Washn. Reproduction estimate, 1906	1645	2205
G 1331. Oregon R R & Navigation Co., in Washn. Built 1875-1899. Original cost.	501	569
G 1332. Oregon R R & Nav Co. Reprod'n est.	501	569
G 1334. Stt of Wis. Val'n by W. D. Pence, '07	7090	10179
G 1336. Stt of Wis. Valuation by W. D. Taylor, 1903-4.	6657	9271
G 1336. Stt of Mich. Valuation by M. E. Cooley, 1900.	7813	10882
G 1347. Stt of Minn. Reprod'n est, 1908	7596	10438

G 1374. Gt. N. syst. Val'n by Chf Engr,* '07-8.	6635	8116

*Appraisal by Chief Engineer of road, in a rate case. Presumably not underestimated. See ¶ 12.

COST DATA

GENERAL ACCOUNT I. ROAD.

Primary Account 1.
Engineering.

Surveys.

22. Under "surveys" we here include reconnaissance, preliminary survey and location, and such other professional engineering work as may be required prior to the beginning of construction.

23. Importance. The adoption of an inferior line means increast construction cost, or increast operation cost for every train during the lifetime of the road, or both. The whole cost of surveys will usually be much < 1% of the total cost of the line; and it is poor economy (especially on important lines) to stint the expenditure upon surveys, in the matter of either salaries, subsistence or appliances and conveniences.

24. Reconnaissance consists of an exploration of *areas*, rather than of *lines*. The party includes usually a chief engineer, a transitman, a topographer, a draftsman, a rodman, one or more axmen, and a cook where required; and the monthly payroll may ordinarily range from $750 to $1,500, depending upon the importance of the line; but the time, devoted to reconnaissance, varies, betw very wide limits, with the importance of the line and the character of the country, especially as to the number of apparently favorable lines requiring investigation. The cost of reconnaissance therefore varies widely; but it will probably seldom exceed say $25 to $50 per mile of constructed line, or 0.10% to 0.25% of the construction cost.

25. Preliminary survey and location. The party will usually include

	Salaries, $/month
Locating engineer	125 to 175
Assistant engineer	100 to 125
Transitman	85 to 100
Leveler	80 to 90
Topographer	70 to 100
Draftsman	70 to 90
Rodman	50 to 65
Chainmen; 2, at $40 to $50	80 to 100
Back flagmen	30 to 40
Tapemen; 1 or 2, at $30 to $45	30 to 90
Stakemen	30 to 35
Axmen; 2 to 5, at $25 to $30	50 to 150
Total; 14 to 18 men	—— ——

Engineering salaries per party per month, when labor costs $1.50/man-day ....$800 to $1160

26. Where the party is to provision itself, add a cook and helper at $60 to $80 total per month. Provisions may range from $175 to $350 per month; or the party may be "boarded" at about the same or a little greater expense. Add other expenses as below:—

	$ per month per party		
Salaries, as above,	800	to	1160
Subsistence,	250	to	500
Team,	75	to	150
Contingencies,	25	to	125
Total,	$1150	to	$1935

27. Preliminary and location cost, per mile of survey, for a given monthly outlay for surveys, depends upon the character of the country and upon weather conditions. Rough country and

severe weather, by reducing the mileage coverd by a given outlay, increase the cost per mile surveyd.

28. In moderately rough country, prelim survey may be expected to cost from $20 to $40 per mile of prelim survey; and location from two to three times these figures per mile of location. In prairie country, half as much, or less; and, in very rugged country, twice as much, or more.

29. The survey cost, per mile of constructed line, may be as much as three or four times the survey costs, above indicated, per mile of line *surveyd*.

30. For a given cost per mile of *survey*, the *line*-mile cost of survey depends upon the character of the country and upon the limitations imposed as to max grade and max curv-sharpness.

31. A ridge, prairie, or river-bank line, offering but little if any choice betw alternate lines, will require fewer miles of prelim survey, per mile of finisht construction, than will a cross-country line, in rough country, which may require the investigation of several promising lines before the best can be selected for location. In rough country, restriction of grades and of curv-sharpness of course increases survey cost per mile of finisht construction.

Engineering.

32. Probable range of engineering cost; deduced from a comparison of eighteen tabulations in "Cost Data" —

	$/line-mile	% of total constru cost
Preliminary and location surveys,	150 to 400	½ to 1
Engineering during construction (laying out of work, and superintendence),	400 to 1300	1.5 to 3
Total "engineering",	550 to 1700	2 to 4

Primary Account 2.

Land for Transportation Purposes.

Real Estate.

33. Perhaps in no other item is greater caution required, when deducing the cost of a proposed line from the actual or estimated costs of other lines, than in that of real estate for right of way, for stations and terminals, for water supply, etc.

34. The price per acre may vary from $10 or less in waste lands, to $20,000 or more for terminal sites in cities; and the cost of such sites increases rapidly with time as a result of city development. Indeed, land is frequently *donated* to railways, by govts or business interests desirous of the services of the road in developing the country or the trade of the city; and, on the other hand, vindictiv or avaricious property-owners frequently hold out for exorbitant prices, which the companies often pay rather than resort to condemnation, which involves legal proceedings, and which restricts the company's use of the land to Ry purposes. Owing to consequential damages and inconvenience to property-holders, it is usually accepted as equitable that land, for Ry purposes, should cost the company from two to five times the market value of adjacent property. See **"the right-of-way multiple,"** ¶¶ 36, 39.

35. The right-of-way width may vary from 50 feet or less for a cheap single track line in prairie country, to 200 ft or more for a low-grade trunk line, with from two to four tracks, deep earth cuttings and high earth embankments. The area and the prices of the lands required, for yards, stations, etc., vary widely with the nature of the traffic.

1 acre per mile	=	8.25 ft right-of-way width;
66 ft width	=	8 acres per mile;
100 ft width	=	12.12 acres per mile.

36. The ratio, $\dfrac{\text{cost of land, to Ry Co.}}{\text{market value of same land, for ordinary purposes}}$ is called **"the right-of-way multiple."**

37. Promoting. The matter is further complicated by the fact that Ry companies frequently purchase a wider right-of-way than their transportn purposes require; expecting to sell the surplus at prices enhanced by the construction of the road, or being compeld to this course as a concession to recalcitrant property-holders.

Examples.

38. In 1906, the Texas R R Commission, in valuing a Ry line, assumed, (G 1354):—

Right-of-way	\$ 50 per acre
Depot grounds	\$100 " "
Reservoir grounds	\$ 25 " "

39. The Western Pacific Ry connects San Francisco, Cal., with Salt Lake City, Utah, passing thru Sacramento, Oakland and other important Cal cities. In Cal, it acquired, for its 377 miles of line in that State, 6064 acres of land = say 16 acres per line-mile, classified as follows by Walter Melvin Wells, Right-of-way Expert for the Cal R R Commissn. Eng-Contr 1913 Aug 20, p 215:—

			Av cost to Ry Co, \$/acre
Exclusiv of San Francisco terminals	Country lands,	85.2%	102
	Suburban property,	8.4%	
	City water-front property,	2.6%	4,630
	City residence property,	1.5%	
	City business property,	2.3%	
		100.0%	450
San Francisco terminals, 177 acres purchast in highly improved city warehouse district			18,862
All classes			985

The prices paid, for the portions acquired by condemnation, were

	Rural and suburban	In cities	
	per acre	per sq ft	per ft front
Market value when purchast	\$15 to \$1,000	\$0.20 to \$0.60	\$0.30 to \$0.40
Cost to Railway Co	\$37 to \$3,672	\$0.24 to \$1.50	\$0.20 to \$1.60

40. For 981 miles of steam and electric railway line in California, investigated by the State R R Commission, including the 377 line-miles of the Western Pacific (¶ 39), Mr. Wells gives

Line-Miles	Character of lands	Acres, est'd	Land Cost to R R Co. Total \$	Per acre est'd \$	Per line-mile \$
226	desert & waste lands,	3,630	37,706	10	167
310	Mt & timber lands,	4,980	89,739	18	289
445	farm lands, and lands in unincorp'd cities,	7,150	743,616	104	1,675
981	totals and averages, rural and unincorp'd,	15,760	871,061	55	890
0	within incorp'd cities including W. Pac San Fran terminals	928	6,529,360	7,036	∞
981	totals and averages,	16,688	7,400,421	444	7,540

41. The following table, referring chiefly to conditions in the middle and far west, illustrates the wide range in values of real estate, both per line-mile and in its ratio to total construction cost. Column A (Constrn) includes real estate cost (Column B). Where, for a given road, two values are stated, under B, or under 100 B/A, the first refers to right-of-way, and the second to real estate acquired for other purposes. Note the diffs in ratio betw these two.

		Line Miles	$/ line-mi A Constrn	$/ line-mi B Rl Est	100B / A
G 1289 Winchester & Beattyv, (Mine R R),	Ky*	8	13,650	428	3.14

		Total, 1895,	3,833	15.8
From ¶ 41	41,200		9.360	22.6

Roadbed Construction.

43. Roadbed construction (construction preliminary to track-laying) may be taken as including I.C.C. primary accounts 3 to 7 inclusiv (see ¶ 18). It is made up principally of Account 3, Grading (including clearing and grubbing); Account 5, Tunnels and Subways; and Account 6, Bridges, Trestles and Culverts.

44. With given unit costs of material and of labor, the line-mile and the track-mile cost of each of the items included under "Roadbed" varies betw very wide limits. Thus, a prairie line may require no tunnels, bridges or trestles, and little or no grading; whereas, in difficult country, nearly the entire line may well require clearing, grubbing and heavy grading, while tunnels, culverts and bridges may be of frequent occurrence; especially where the modern tendency to reduction of operation cost, by improvement in alinement and in grade, necessitates more numerous and heavier cuts and fills, culverts, bridges, etc.

Primary Account 3.
Grading.

45. Grading includes clearing and grubbing, blasting, breakwaters, bulkheading, excavation and embankment, filling in under bridges and trestles and over culverts, steam shovel operation, use of spoil banks, revetments and retaining walls, riprap, wing dams, and temporary trestles for fills.

Clearing and grubbing.

46. The cost of clearing (removing trees and brush) and that of grubbing (removing stumps and roots) are sometimes included (in bidding) with that of grading; or one price may be named for clearing and grubbing, together; but clearing and grubbing are frequently estimated separately, because often only a portion of the cleard area requires grubbing. Thus, the stumps and roots may be left in place under embankments, except where these are very shallow.

47. Units. The cost of both clearing and grubbing is usually stated in dollars per acre; sometimes in dollars per "square" of 10,000 sq ft. The cost of grubbing is sometimes given in dollars per sq rod (160 sq rods = 1 acre) and sometimes in dollars per "station", covering the right-of-way along 100 ft of line.

48. Elements affecting cost. The clearing and grubbing cost, per unit of area, depends upon the density, species and size of the timbering, upon the amount and character of the underbrush, upon the character and accessibility of the ground, and upon the disposition to be made of the material removed. This cost may be largely or quite offset, or even exceeded, by the value of the timber cut. The apparent grubbing cost is affected also by the method to be employd in the subsequent grading. Thus, a steam shovel (in earth), or blasting (in rock), does much of the work which ordinarily would be clast under grubbing. On the other hand, the use of scrapers requires careful preliminary grubbing; and that of the elevating grader is still more exacting.

49. The line-mile cost, for clearing and grubbing, depends further upon the clearing area per line-mile, and this, in turn, upon the right-of-way width, and upon the proportion of this occupied by woodland and brush.

1	5	8 25	10	16 5		feet width =
0 1212	0 606	1	1.212	2		acres per mile.
20	24.75	30	33	40	41 25	feet width =
2 424	3	3.636	4	4.848	5	acres per mile.
49 5	50	82.5	100	165	200	feet width =
6	6.06	10	12.12	20	24.24	acres per mile.

50. Usually, from 1 to 6 acres per mile (= a uniform strip from 8.25 to 49.5 ft wide) requires clearing

51. The site of the Brockton, Mass., filter beds had 480 trees (from 6 to 24 ins diam) per acre = one tree to each 91 sq ft; a dense growth. G 1045.

52. The costs of clearing and of grubbing may ordinarily be expected to range as follows:—

	Clearing	Grubbing	Clearing and grubbing
Per tree or stump	\$ 1 to 2	\$ 0 05 to 1	\$ 1 to 3
Per acre	\$25 to 150	\$25 to 150	\$ 50 to 300
Commonly assumed at	....	....	.....\$50
Per line-mile	\$50 to 600	\$50 to 300	\$100 to 1000

Earthwork.

53. "Grading" proper includes (besides clearing and grubbing), "earthwork", or the excavation, transportation, depositing and compacting of earth, in its various forms, and of gravel, hardpan (cemented gravel), loose rock and solid rock. Where the cuts furnish insufficient quantities for the fills, the deficiency is made up by taking material from "borrow-pits", and the work is then usually classified as "embankment".

54. Elements affecting cost. The cubic-yard cost of earthwork varies widely with the nature of the material, with its accessibility, with its quantities, with the facilities for handling it, with the skill of the contractor, and with the wage rate, but especially with the dist thru which it must be transported. See pp 1024-1035. On any considerable work, however, the long and the short hauls are regarded as compensating, and it is customary to contract at a fixt cu yd price for each of the several kinds of material encountered,

with a specified limit of haul-length, beyond which the contractor is paid (usually one cent per cu yd of "overhaul") for each 100 ft of excess dist.

55. Ordinarily the cubic-yard cost of earthwork (hauling included), in cents, may be taken as ranging as follows:—

		Average
Earth, ...	15 to 30	22
Hardpan and cemented gravel, ..	35 to 45	40
Loose rock, ...	40 to 55	50
Hard rock, ...	75 to 110	100
Grading, all materials, average,	30 to 45	37

56. Cost per mile. For a given cu yd cost, the mile costs, for earthwork, of course vary betw very wide limits, depending upon the quantity of grading required per mile, which, in turn, depends upon the character of the country and upon the necessity for favorable grade and alinement in the finisht line; a given country naturally requiring more earthwork for a line of closely limited grades and curvature, than for one where heavier grades, and sharper and longer curvs, may be permitted. See table of itemized costs, ¶ 145.

Earthwork Cost, Classified by Materials.

57. In the following table, under each material, the rys are arranged in the descending order of their grading cost for that material, as a percentage of the total earthwork cost. These data (mostly in round numbers) serv to give an idea as to the range of grading quantities and costs to be expected, per line-mile and per track-mile. For miles of line and of track, in the cases here used, see ¶ 21. For their total line-mile and track-mile costs, see ¶ 138.

Primary Account 5.
Tunnels and Subways.

Tunnels

58. Elements affecting cost. Tunnel cost, per cu yd, depends upon the character of the material to be removed, and the facilities for its removal; upon the necessity for, and the required character of, lining; upon the quantities of water encounterd and the facilities for its removal; upon the accessibility of the location; upon the cost of labor at the site; upon the skill of the contractor, etc. It is usually less for contract work than for work done with the company's forces by day's labor. In long tunnels, owing to longer hauls, to the necessity for sinking shafts, to the necessity and difficulty of ventilation, and to the more expensiv character of the plant required, it is usually (other things equal) greater than in short tunnels. It is less for the bench than for the headings; and, for the same reason, it should (especially in small sections) decrease as the cross-section area increases.

59. Cost with labor at $1.00 per day. A study of numerous records, including those given in "Cost Data", indicates that, reduced to a uniform labor basis of $1.00/day, the **average contract price, per cubic unit,** for the entire section, of rock tunnels, may be expected to range, under ordinary circumstances, as follows:

Contract prices. Labor at $1 per day.	A. Cents per cu ft = cts/lin ft/sq ft of section area		$ per cu yd = 27 × A/100	
	cents		$	
Tunnel, excavated, ...	6 to 10;	av 7.8	1.60 to 2.70;	av 2.10
lined with timber, ...	8.5 to 12;	av 10.5	2.30 to 3.25;	av 2.80
conc or masonry, ...	10 to 15;	av 12.5	2.70 to 4.00;	av 3.35

60. Cost with labor at other rates. For the actual cost, in a given case, multiply the costs, in ¶ 59, by actual labor cost, in $ per day.

61. Earth tunnels, from one-third to one-half of these figures.

62. Actual cost; to skild contractors, about one-third less than contract prices; to company, by day labor, from a half to two-thirds more than contract prices.

63. Cost per linear foot. For a given cu yd cost, the lin-ft cost, for the entire cross-sec, varies (other things equal) directly with the number of cu yds per lin ft; and this depends upon the cross-sec area. Single-track standard-gage Ry tunnels usually measure from 14 to 20 ft in width, and double-track tunnels from 25 to 30 ft. The height is usually from 22 to 24 ft. A section, which would suffice for an unlined tunnel, must of course be enlarged to make room for a lining if this is required.

For given conditions, the cross-sec area, for double-track, may be from 1.6 to 1.8 times that for single track.

64. Range of variation of tunnel line-mile cost (see ¶ 145).

		Tunnel cost, in $ per line-mile of road

Subways. See ¶ 144.

Primary Account 6
Bridges, Trestles and Culverts

Bridges.

65. Costs of bridges may be expected to range as follows:—

Steel bridges				
	superstructure alone, erected		including substrct	
	per lb of steelwork cents	per lin ft of strctr dollars	per lb of steelwork cents	per lin ft of strctr dollars
Single-track, moderate span, usual constr'n,	3 to 4	30 to 50	6 to 7	50 to 100
Special cases, wider roadways, long span,	to 7	to 500	to 15	to 2000

Concrete and masonry bridges		
	per sq ft of roadwy dollars	per lin ft of strctr dollars
Single-track bridges of moderate span and usual construction,	3 to 6	50 to 100
Special cases, wider roadways, long spans,	to 12	to 300

For cost of steel, see p 986.
For cost of masonry, see pp 601, 988.
For cost of concrete, see pp 988, 1375.

66. Weights of steel. The following straight-line formula, for wts of steel in highway and in single-track railway bridge superstructures, including their floor systems, is condenst from those of Messrs. J. B. Johnson and H. G. Tyrrell G 1471, 1474. For double-track railway bridges, add 90%. See our pp 731 and 738.

$$W = L(m + nL);$$

where
W = wt of structure in lbs; L = span in ft; and
m, n = coefficients, as follows:

Bridges for	Refs to notes below	m	n
Highways	A	50	2
Steam railways			
Plate Girders			
Deck		100 to 150	9 to 12
Thru		500 to 600	10 to 12
Truss bridges	B	200 to 400	5 to 7
	C	600 to 650	7
Electric Railways			
I beams (spans 5 to 20 ft)		50	5
Deck plate girders	D	30	5
Riveted trusses	E	200	0 8
	F	250	1.5

A Live load, 100 lbs/sq ft. Add or deduct 15 lbs/span-ft for each 2 ft of variation from 16 ft roadway width.
B For two 100-ton locos and 4000 lbs per lin ft of train.
C. For spans of 30 to 230 ft. Cooper loading E-50 (p 755); two 177.5-ton locos and 5000 lbs per lin ft of train.
D Live load, 2000 lbs/lin ft.
E. " ", 1000 " " 15-ton cars; spans 40 to 200 ft.
F. " ", 2000 " " 30-ton cars; " 20 to 180 ft.

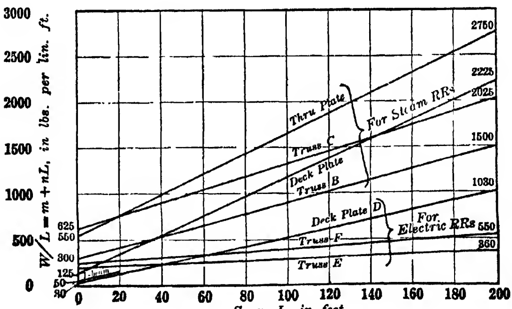

Fig. 1.

67. Fig 1 shows, approx, for each class, the average value of $W/L = m + nL$ = wt/span-ft, in railway bridge superstructures, as given by this equation.

68. For trestle bents and piers for steam railway bridges, add 9 lbs/sq ft of profile area from ground to rail-base; for electric railways, 6 lbs.

Trestles.

69. Quantities of timber in trestles, including 164 ft B M of deck timber per lin ft; and in pile trestles of 4-pile bents, 16 ft c to c, G 966.

$$F = L(mH + n) = mA + nL;$$
$$P = L(H + 20)/4$$

wherein:

F = total ft B M in structure;
L = length of trestle, in ft;
A = profile area of trestle, in sq ft, from ground to 4 ft below rail-base;
H = A/L = average height;
P = lin ft of piling in pile trestle;
m and n = coefficients as below.

	In pile trestles		In trestles			
For heights	up to 15′	15′ to 25′	25′	25′ to 50′	50′ to 75′	75′ to 125′
coefficients						
m =	0	0	6	8	9	10
n =	185	200	220	240	240	240

70. Single-track pile and timber trestles, of moderate heights, may be expected to **cost** from $5 to $10 per ft of length. For more than one track, to $15, $20 and more.

For costs of timber, see p 984.

Culverts.

For wts and costs of cast iron pipe, see pp 656, 658 and 995.
For those of vitrified pipe, and discounts, see pp 575 and 995.

71. The costs per lineal foot of culverts, in place, vary chiefly with the labor cost of placing.

Primary Accounts 8 to 12, inclusiv.
Track.

77. Trackwork may be taken as including I.C.C. Primary Accounts 8 to 12 inclusiv, as follows:—

8. Ties
9. Rails
10. Other track material (including turnouts)
11. Ballast
12. Track laying and Surfacing.

Primary Accounts 11 and 8. Ballast and Ties.

78. Ballast and ties may be expected to cost as follows:—

Ballast, cts/cu yd	Delivered	In track
Rock	50 to 70	75 to 110
Gravel and sand	20 to 30	30 to 60
Ties, cents each	30 to 60	40 to 80

79. Second-hand ties may cost from one-third to one-half as much as new ties; creosoting, from 25 to 35 cts/tie; other processes, 10 to 20 cts; switch ties, from $10 to $20 per 1000 ft B.M.; $20 to $60 per set.

80. Renewing ties may be expected to cost, approx,

in stone ballast,	about 20 cents per tie;
in loose gravel,	6 to 10 cents per tie;
in cemented gravel,	10 to 20 cents per tie;
in hard slag,	9 to 15 cents per tie.

81. Tie Spacing.

Dist, cen to cen	Ties per 30-ft rail	Ties per 33-ft rail	Ties per mile
1′ 8″ = $^5/_3$ ft	18	$19^4/_5$	3168
1′ 9″ = $^7/_4$ ft	$17^1/_7$	$18^6/_7$	3017
1′ 10″ = $^{11}/_6$ ft	$16^4/_{11}$	18	2880
1′ 11″ = $^{23}/_{12}$ ft	$15^{15}/_{23}$	$17^5/_{23}$	2755
2′ 0″ = 2 ft	15	$16^1/_2$	2640
2′ 1″ = $^{25}/_{12}$ ft	$14^2/_5$	$15^{21}/_{25}$	2534
2′ 2″ = $^{13}/_6$ ft	$13^{11}/_{13}$	$15^3/_{13}$	2437
2′ 3″ = $^9/_4$ ft	$13^1/_3$	$14^2/_3$	2347
2′ 4″ = $^7/_3$ ft	$12^6/_7$	$14^1/_7$	2263
2′ 5″ = $^{29}/_{12}$ ft	$12^{12}/_{29}$	$13^{19}/_{29}$	2185
2′ 6″ = $^5/_2$ ft	12	$13^1/_5$	2112

Primary Account 9. Rails.

82. Weights of rails, in pounds.

per yard;	50	60	70	80	90	100
per single-track mile;	176,000	211,200	246,400	281,600	316,800	352,000

Weight, in pounds per single-track mile
= 2 × 1760 × wt in lbs/yd of rail.

83. Cost. From 1888 to 1914, the price of rails, at mill, ranged only betw $24 and $32 per ton of 2240 lbs, except in 1897-8, when it fell to $18.00. Freight cost is usually about ½ ct/ton/mile. Second-hand rails usually cost a little more than half as much as new rails.

Primary Account 10. Other Track Material.

84. Joints and fastenings.

	lbs/track-mile	cts/lb	$/track-mile
Angle plates,	15,000 to 20,000	2 to 2¼	900 to 1400
Spikes,	6,000 to 7,000		
Tie plates,	25,000 to 35,000		
Bolts and nuts,	1,500 to 2,000	2½ to 3	35 to 60
Rail braces,	4,500 to 8,750	3 to 3½	135 to 300

1500 to 2500 rail braces per mile at 10 to 12 cts each, 3 to 3.5 lbs. each.

Rail joints, $2.50 to $5 00 per joint.

The two angle bars together (see p 823*b*) will weigh from 20 to 40 lbs per lin ft.

Turnouts.

85. Switches, from $20 to $30 per set.

86. The cost of frogs increases with the frog number (see Turnouts and Crossings, Part II, ¶ 4).

Rigid frogs, Nos 8 to 10, $20 to $35 each; spring-rail frogs, $45 to $55 each; crossing frogs, $225 to $325. Switch-stands, $5 to $10 each.

87. Complete turnout, $150 to $200, including ties, stand, connecting-rods, rail braces, lamp and gard-rails.

88. Sidings, from $0.80 to $1.20 per lin ft. See costs of items, ¶ 95.

Account 12. Track Laying and Surfacing.

89. Track-laying includes unloading the ties and rails, trimming earth to true grade, delivering and placing ties and rails, curving and joining rails.

90. Surfacing includes shoveling the earth in between the ties, alining the track, and tamping.

For costs of laying and surfacing, see estimates of track-mile cost, ¶ 145.

Track Cost per Mile.

91. Practically, each mile of *track* requires its 5280 lin ft of ballast, of ties, and of laying and surfacing, and its 10,560 lin ft of rails, with their joints and other fastenings. Only the item of turnouts is subject to notable variation, in cost/mile, as betw diff lines of the same general character; and this item (see tables below) is relativly insignificant; its cost ranging usually betw only 1 and 3% of the total track cost.

92. Hence, for given unit costs and given construction, the *track*-mile cost of track (given in our tables, below, ¶ 95) is practically constant; and the *line*-mile cost is practically = *track*-mile cost × number of tracks.

93. Elements affecting cost. With given material unit costs, the track-mile cost of ballast depends upon the ballast cross section; that of ties upon tie size and spacing (¶ 81); that of rails and fastenings upon wt/yd; and that of turnouts upon their construction and upon the number required per mile.

94. Increasing cost. Improvements in manufacture (and particularly large-scale mfr, the consolidation of small plants into larger systems under common control, and increast effort for efficiency) have resulted in material reduction in unit rail costs; but, as above noted (¶ 83), no great and progressiv reduction has taken place since 1887; and the unit costs of the other items (notably that of ties, following the growing scarcity of timber) have been advancing. Moreover, increase in wts of rolling stock and in carloadings have called for increasing solidity of construction. Hence, the tendency of track cost, per track-mile, is upward.

95. Table of approx costs, deduced from eighteen statements given in "Cost Data", and covering a total of over 48,000 track-miles. Practically all of the mileage, here represented, is in the western United States. See ¶ 96.

Primary Accounts 13-15 inclusiv.
Track Structures.

Primary Account 13. Right-of-way Fences.

97. Barbed wire fence.
Posts. Wood or concrete, 10 to 30 cts each. Usually 15 to 20. Spaced from 10 to 20 ft cens. Setting, 5 to 7 cts each.
Wire, 2.5 to 3.5 cts/lb.
Barbd wire fence, complete, 2.5 to 5.5 cts/lin ft of fence.

98. Post and rail fence.
Posts, 6 to 7 ins × 2 to 3 ins, 8 ft long, set 3 ft in ground, 6 to 20 cts each. Set at 8 to 9 ft cens.
Post and rail fence. 5 to 12 cts/lin ft of fence. Usual contract price, in Mass., with one coat white lead, 15 cts/lin ft.
Worm fences, 7 rails high, about one-fourth less than post-and-rail
Picket fence, painted, 90 cts to $1.50/lin ft. Saml Tobias Wagner, Am Soc C E, Trans, 1913 Dec, Vol 76.

99. Gas-pipe railing, with cast iron posts, Phila & Reading Ry, Phila. Contract price, attacht to walls, 58 to 75 cts/lin ft.

Primary Account 14. Snow and Sand Fences and Snowsheds.

100. Snow fences, from 10 to 20 cts/lin ft.

101. Snow sheds (not to withstand avalanches) $10 to $20/lin ft. for avalanches, $40 to $70/lin ft.
Of *concrete*, Gt Northn Ry in Washn; per lin ft of shed; 8 cu yds conc, 1500 lbs steel, $141. Ry Age Gaz, 1911 Jan 13, p 83

Primary Account 15. Crossings and Signs.

102. The line-mile cost of crossings, cattle-gards and signs, will seldom exceed $100, but may reach $200 or $300.

Primary Accounts 16 to 20, inclusiv.
Buildings.

Primary Account 16. Station and Office Buildings.

Stations.

103. Frt, passr and combination stations, of frame or brick; $1 to $2/sq ft of ground coverd, for small, plain one-story frame or brick buildings; $3.50 to $5 or over for larger and more elaborate structures. A second story may add two-fifths to the cost.
104. Columbia Ave passr sta, Phila & Reading Ry, Phila. Main building, ornamental, two stories, 170 × 150 ft; two concrete platforms, 800 ft long; umbrella sheds; four baggage elevators; total cost, $217,134 = $8.50/sq ft. Three smaller and semi-suburban, two-story passr stations, with tunnels and baggage elevators, in Phila., $43,000 to $63,000 each. Saml Tobias Wagner, Am Soc C E Transns, 1913 Dec, Vol 76, p 1866.
105. Passr stations. Average size, in towns of from 10,000 to 15,000 population, on 31 rys, about 2000 sq ft. (Comm, Am Ry Eng & M W Assn, 1904.)

106. Platforms, per sq-ft:—cinder, 5 to 7 cts; wood, 8 to 12 cts; concrete, 10 to 20 cts; brick, 20 to 30 cts.

107. Track scales, from $1200 to $3000 each, installed, according to size and capacity.

Primary Account 17. Roadway Buildings.

108. Section houses; $0.70 to $1.30/sq ft of ground occupied. Gillette, p 1121, mentions five three-room frame section-houses ("Jap houses"), of very cheap construction, about $0.50 to $0.60 per sq ft. Tool, hand-car and material store houses, $0.25 to $0.50 per sq ft.

95. Table of approx costs, deduced from eighteen statements given in "Cost Data", and covering a total of over 48,000 track-miles. Practically all of the mileage, here represented, is in the western United States. See ¶ 96.

Primary Account	Dollars per track-mile: Probable Max	Probable Min	Average	% of total track cost: Max	Min	Average
11. Ballast,	1200	500	800	13	7	12

For GENERAL ACCOUNT II. EQUIPMENT,
See ¶¶ 132, etc.

GENERAL ACCOUNT III. GENERAL EXPENDITURES.

130. Under this head may be clast such expenses as that of effecting company organization, including necessary legislation; that of obtaining a certificate of public convenience and necessity (required in some states); that of obtaining local franchises and consents; that of compensation to "promoters" (an item subject to grave abuse); and those connected with the issue and marketing of stocks and bonds, including official authorization, and discount upon those securities which must be sold below par. Their total varies widely. Mr. Walter Loring Webb ("Railroad Construction", 1905, p 394) says:—"It has been estimated that about 2% of the railway capital of Great Britain has been spent in Parliamentary expenses over the charters."

---

*Assumed for our table.

†Item No.	Item.
16,	Stations.
20,	Shops and engin houses.
18, 19,	Water and fuel stations.
21-24,	Docks, wharvs, warehouses, stock yds, grain elevators.
35,	Miscellaneous buildings.
13,	Fencing, etc.
26, 27,	Telegraph, telephone and signals.
44,	Shop machinery.
14,	Snow and ice protection.

Primary Accounts 73 (Law) and 76 (Interest during construction.)

131. In statements of actual cost, the item of interest, plus legal expenses, usually ranges between 2.5 and 5% of the total construction cost exclusiv of rolling stock; but, in estimates, valuations and appraisals, the estimators, by assuming long periods of non-remunerativ conditions, sometimes arrive at much higher figures. Thus, in the case of the Gt Northn Ry System, G 1374, where the cost, exclusiv of equipment, amounted to $56,330/line-mile, the Chf Engr estimated interest at $5690 per line-mile, and legal expenses at $563/line-mile; total, $6253/line-mile.

GENERAL ACCOUNT II. EQUIPMENT.

Primary Accounts 51 (Steam Locomotivs) and 53, 54, 57 (Freight-train and Passenger-train cars and Work Equipment.)

132. Locomotiv and tender (7 to 9 cts per pound)

Passenger and switching-,	$10,000 to $12,000 each
Atlantic type, and freight-,	$15,000 to $17,000 "

133. Cars

Pullman-,	$12,000 to $15,000 "
Passenger-,	$ 6,000 to $ 8,000 "
Baggage-,	$ 4,000 to $ 5,000 "
Freight-,	$ 600 to $ 700 "

For GENERAL ACCOUNT III. GENERAL EXPENDITURES

See ¶¶ 130, 131.

TOTAL COSTS PER MILE

Property Investment.

135. From the Interstate Commerce Commission's 27th Annual Report on the Statistics of Railways in the United States, for the year ended June 30, 1914, Washington, 1915, Statement No. 44 A, pp [illegible]-4, we deduce the following data respecting "property investment" in "road and equipment" for the roads represented in the statement.

Class I. Roads having annl operating revenues > $1,000,000;
Class II. " " " " " from $100,000 to $1,000,000.

For definitions of eastern, southern and western districts, see Fig. 2.

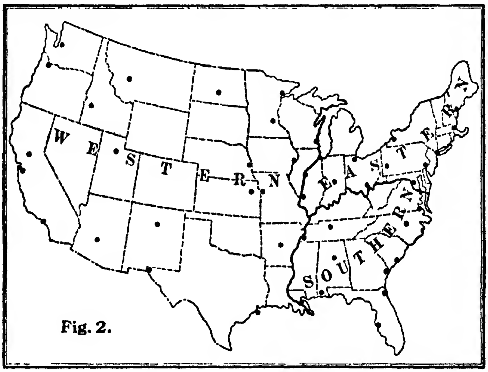

Fig. 2.

	Class I			
	Eastern	Southern	Western	Tot U. S.
Track-miles	32,121	33,418	105,964	171,503
Property investment, $ per track-mile;	138,000	67,000	61,700	77,000
	Class II	Tot Op'g	Non-op'g	U. S.
Track-miles	18,367	189,870	37,534	227,404
Property investment, $ per track-mile;	43,300	73,800	76,000	74,200

136. For the *line*-mile property investment of the 189,870 operating track-miles represented in the foregoing statement, we have (see Statistics of Rys in U. S., pp 12 and 13):

$$\frac{\text{Total track-miles operated in U. S.}}{\text{Total line-miles operated in U. S.}} = \frac{387{,}208}{256{,}547} = \text{say } 1.5$$

Hence
line-mile property investment = 1.5 × $73,800 = $110,700.

137. Funded Debt. The funded debt (1914) of the Class I and Class II roads and their nonoperating subsidiaries (a total of 243,790 line-miles), as given on p 32 of "Statistics" for 1914, amounts to $11,566,541,553, or $47,400 per line-mile. Assuming (see ¶ 136) 1.5 track-miles for each line-mile, we have: Funded debt, per track-mile = $47,400/1.5 = $31,600.

Total constrn costs, per line-mile & per track-mile.

138. The following table indicates (mostly in round numbers) the range of total construction costs (including right-of-way, unless otherwise stated) per line-mile and per track-mile. The track-mile costs are lower than would be those of single-track lines of the same character.

Dates given ("E-C, 1907 Jun 26," etc) refer to Engineering-Contracting.

For characteristics of lines, see list of Gillette data, ¶ 21.

"By 'Commercial value' is meant the estimate placed upon the worth of a property regarded as a business proposition." p 8. "An effort was made, also, to test the results submitted in this report ("Commercial value") by the formal or implied valuations of railway properties made by state officials." ("Valuation for assessment"), p. 13. From Census Bulletin 21.

See "The Valuation of Public Service Corporation Property," by Henry Earle Riggs, Am Soc C E, Trans, 1911 June, Vol 72, p 15, Table 1.

140. Costs per mile of first class RRs. The following figures of cost per mile of first-class railroads are condenst and classified from R R Gaz of 1906. They include preliminary surveys, clearing right of way, grading, roadbed, ties, rails, ballast and side tracks, in shape for operation, but not real estate, stations, rolling stock and signals. *s* = single track. *d* = double track.

Six first class railroads in eastern U.S., with steel bridges, concrete abuts and piers, 80-lb rail, and stone or gravel ballast.

	Year built	Miles of line	Miles of sid'gs	$ per line-mile	Conditions
A	1902	9.06 *s*	5.45	26,300	River line. Considerable hill-side cut & fill in earth & loose rock. Culverts, C I pipe & conc. No tunnels. Few bridges.
B	1903	15.77 *s*	3.61	37,014	River line. Heavy side-hill work, earth and loose rock. 3 river crossings.
C	1901	30.08 *s*	6.64	60,628	River line. Sinuous alinement. 3 crossings of river 300-500′ wide. 4 tunnels = 1.33 miles total.
D	1903	3.60 *d*	0.00	76,336	Detour ar'd city. Sand and gravel. Heavy work at 4-track R R crossing Highway crossings. 2 deep ravines.
E	1899	1.57 *d*	0.00	105,186	Connection betw 2 main lines. 4-track R R crossing. Highway crossing. Heavy embankments. Extensiv bridging & grade-changes.
F	1898	11.00 *d*	0.00	50,000	Detour ar'd city. 4 overhead and 5 underhead trunk-line R R crossings. Heavy cuts & fills; long hauls. 3 stream crossings.

First class branch line in Texas:

	Year built	Miles of line	Miles of sid'gs	$ per line-mile	Conditions
	1903 to 1904	12.13 *s*	1.52	19,649	75-lb rail. Mostly tangent on level ridge. R R crossing. Few openings. No side-hill cuts. Considerable fill. Earth; some loose rock.

Through trunk-line work, east of Chicago.

	Year built	Miles of line	Miles of sid'gs	$ per line-mile	Conditions
A	1903	10.72 *s*	....	78,000	Low-grade line; 85-lb rail; 2/3 excavated in rock; 1/3 clay & loam.
B	1903	4.10 *s*	2.35	40,700	Ohio. Mine branch. Earth & solid rock. Ravine crossing; Single-track, timber-lined summit tunnel, 475′ long; pipe culverts; timber trestles.
C	1903-4	12.48 *s*	0.50	40,000	W Va. Bituminous coal country. River to river; crossing summit.
D	1902-3	8.10 *d*	....	154,000	W Va. Cut-off. Tunnel 4120′ long. 0.3% grade eastbound; 0.8% westbound.
E	1903-5	51.84 *d*	25.00	100,000	Ohio. Low-grade line. Heavy grading & masonry. Grade-crossings generally avoided.

141. Eng News, 1909 Dec 2, p 623. reprints, from Archiv für Eisenbahnwesen, a table from which we select the following:

	Date	Miles*	"Construction capital" in millions of dollars	$ per mile*
Europe	1904-1908†	181,853	23,588	130,000
Germany	1907	35,058	3,840	108,500
France	1905	28,973	3,520	122,000
Gt Britain & Ireland	1904	22,630	6,085	271,000
Canada	1907 Jun 30	22,447	1,295	58,000
Cuba	1905	1,534	66	43,100

Track Elevation.

142. In 1907 to 1911, the Philadelphia & Reading Railway Co. eliminated grade-crossings on its line betw Green St and Wayne Junc, Philadelphia, 4.3 line-miles. The work included

3,365 ft of 4-track steel viaduct, 27,180 tons,
11 signal bridges,
67,500 cu yds third-class masonry in retaining walls,
151,800 " concrete " in abuts and walls
430,400 " embankment,
4,322,000 ft lumber in temporary trestles,
16 stations and other buildings (including Columbia Ave station, ¶ 104, costing $217,134),
30.1 miles of permanent single track,
46 industrial connections reconstructed,
7 miles telegraph, telephone and electric light conduit,
139,620 cu yds excavation for street-grade changes,
18,306 feet of sewers, $276,679,
104,312 sq yds of street driveway and sidewalk paving.

The total estimated cost was $7,659,740, or say = $1,785,000 per line-mile = $255,300 per track-mile.

Sam'l Tobias Wagner, Am Soc C E, Trans, 1913, Dec, Vol 76.

Elevated and Subway RRs.

143. Elevated railroads. Per mile; total.

G 1376-1379. New York and Brooklyn. Double-track, exclusive of equipment, $300,000 to $350,000 per double-track mile. (No real estate cost.)

144. Subway.

G 1392. New York. A half-mile, double-track, cost the contractors about $800,000, made up approx as follows:—

Earth excavation	410,000
Rock "	5,000
Concrete	90,000
Steel	120,000
Underpinning, etc	125,000
Other items	50,000
	$800,000

For itemized and total cost per mile of surface electric lines see ¶ 146.

*Whether line-miles or track-miles is not stated.
†Includes Netherlands, 1897, with 1653 miles, $138 million.

ITEMIZED COSTS PER MILE

145. The following table gives the itemized cost of steam railroads, per line-mile and per track-mile, and the percentages of total construction cost (including equipment cost) for three typical lines, representing, respectivly, the approx max, mean and min of the usual range of cost, viz:

	G 1319			G 1347			G 1290

146. Surface electric railroads. The discrepancies, betw the totals of the following statements and estimates, are explaind partly by the wide diffs betw the given per-mile costs of certain items, and partly by the omission, from some of the statements and estimates, of items included in the others. The more important of these omitted items are noted below. Owing to diffs of classification betw the several authors, we have been obliged, in some cases, to resort to assumption in proportioning the costs.

G 1417. First-class third-rail suburban line, 62.5 miles long, of which 6.5 miles were laid in city streets. Exclusiv of real estate.

G 1418. Estimate. Interurban trolley R R, based upon experience in New England in 1902. Exclusive of buildings, power and equipment.

G 1419. Third-rail line. (The total, for an otherwise similar trolley line, was $832 less per line-mile). Exclusiv of land, grading, bridges, trestles and culverts. "Electric Railways," by Sydney W. Ashe, 1907

G 1438. Estimate. 3 miles of double-track trolley line. Exclusiv of grading, bridges, trestles and culverts. "Street Railways," by C. B. Fairchild, 1892.

G 1440. Estimate. Max cost of 4-track third rail suburban R R. Exclusiv of engineering. "Electric Railway Economics," by W. C. Gottschall, 1903.

Each of these expense items is, however, subject to wide variation, not only as betw different roads, but, on the same road, from year to year. A road with many bridges, deep cuts, high embankments, etc, to be kept in repair, will have heavier maintenance of way cost than one which has but few of these; and this item may be relativly small one year, and twice as great the next. Fuel may be cheap on one road, and dear on another; and this of course materially affects the cost of motiv power. And so with the other items. Some times the annual cost of maint of way exceeds that of motiv power and cars together. At others, the cost of conducting transportation is fully half the total expense.

Train-mile cost (see p 1081. ¶ 6) in the United States for 1911, according to the Report of the Interstate Commerce Commission for 1911, averaged as follows:

		Gross annual operation cost	Train-mile cost
On railroads of Class	I, not less than.	$1,000,000	$1.555
" " " "	II, between	$1,000,000 and $100,000	$1.349
" " " "	III, not over	$100,000	$1.410

When a road does a very large business, of such a character that the trains may be heavy and the cars full (as on coal-carrying roads) the train-mile cost is large, and vice versa, altho, on coal roads, half the train-miles are run with empty cars.

Table 4. Revenue per mile, per passenger-mile, and per ton-mile, total gross earnings and expenses per line-mile, and operating ratio of some of the Class I railroad Companies in the United States in 1914 From Report of the Interstate Commerce Commission for Year ending June 30, 1914. Class I railroads are those having annual operating revenues greater than $1,000,000.

In the above table only the five largest railroads in each district (size being determined by mileage *operated*) are shown.

*Operations partly electric. †Includes 55 miles in Canada. ‡Includes 245 miles in Canada. §Includes 1,209 miles in Canada.
**Includes 732 miles in Canada, and 52 in Mexico. ††Includes 1,941 miles in Canada, and 52 in Mexico.

PRESERVATION OF TIMBER.

Art. 1. (a) **The decay of timber** is caused by the growth and activities of fungi. The minute spores of one of these fungi, germinating on a piece of wood, send out fine threads, which enter the wood cells and soon give off a complex compound called a ferment or enzyme, which dissolves certain parts of the wood fibre. The dissolved fibre serves as food for the fungus. The threads throw out branches and sub-branches, and soon the timber is permeated by a mass of such threads, the growing parts of which give off ferment. The action of the ferment changes the chemical and physical properties of the wood, rendering it, in some cases, like brown charcoal, in others white, soft and stringy, and the wood is said to be rotten or decayed. Eventually some of the threads grow out from the surface of the timber, and form toadstools and other excrescences. Under these are found cavities containing thousands of spores, which, when ripe, are blown off into the air and settle upon other timbers, where the process is repeated. Moisture and heat are favorable to the growth of the fungi, as are also the starches, sugars and oils found in the cells of the sapwood but wanting in the heartwood. If protected from the action of these fungi, wood will last indefinitely. Hence the accumulation of deadwood should be avoided.* If air is excluded, as when timber is kept constantly and entirely immersed in salt or fresh water, the fungi cannot thrive. Sap, confined in timber with air, ferments, producing **dry rot**; as where beams are enclosed air-tight in brickwork, etc.; and where green timber is painted or varnished, or treated with creosote, etc. The sap then not only prevents the thorough penetration of the oil, etc, but may cause the greater part of the wood to rot although its firm outer shell gives it a deceptive appearance of strength. (b) Sap should therefore be first removed by **seasoning**; *i e*, either by drying the wood in air at natural or higher temperatures, or by first steaming the wood under pres so as to vaporize the sap, and then removing the latter by means of a vacuum. Thorough seasoning of large timbers in dry air at ordinary temperatures may require years; and too rapid kiln-drying cracks and weakens the wood. But it is questionable whether steaming and vacuum remove sap as thoroughly as do the slower dry processes. (c) Alternate exposure to water and air is very destructive. It causes **wet rot**.

Art. 2. Sea-worms. The *limnoria terebrans* works from near high-water mark to a little below the surface of mud bottom; the *teredo navalis* within somewhat less limits. The teredo is said to be rendered less active by the presence of sewage in water.

Art. 3. (a) The best timber-preserving processes are practically **useless unless thoroughly well done.** If the gain in durability will not warrant the expenditure of time and money reqd for this, it is more economical to use the wood in its natural state. (b) **The woods best adapted to treatment** are those of an open or porous texture. They absorb the oil etc better than the denser woods; and their cheapness renders the use of the treatment more economical. (c) Most of the processes in common use seem to render wood less combustible. (d) After treatment by any process, the wood should be well dried before using.

Art. 4. (a) **Creosote oil, or dead oil,** is the best known preservative. Against sea-worms it is effective for 15 to 25 years, and is the only known protection. (b) As temporary expedients, piles are sometimes covered with sheet metal, or with broad-headed nails driven close together. These rust or wear away in a few years. Oak piles, cut in January, and driven with the bark on, have resisted the teredo for 4 or 5 years; and cypress piles, well charred, for 9 years. (c) For ordinary exposures on land, 8 to 10 lbs of creosote oil **per cub ft** are reqd = say 670 to 830 lbs per 1000 ft board measure = 30 to 40 lbs per cross tie of 4 cub ft. For protection against sea-worms 10 to 12 lbs per cub ft suffice in climates like those of Great Britain and the Northern U S; but in warmer waters where the teredo is very active, from 14 to 20 lbs per cub ft are used. Large timbers may not require saturation throughout, and thus may take less per cub ft. But see (i) and end of Art. 1 (a). (d) Creosote oil **weighs** about 8.8 lbs per U. S. gallon. (e) The sticks should be reduced to their intended final dimensions and framed (if framing is reqd) before treatment; especially if for exposure to teredo, which

---

* See paper by Dr. Hermann von Schrenk, read before the American Railway Engineering and Maintenance of Way Association, March, 1901.

is sure to attack any spots which (as by subsequent cutting) are left unprotected. (f) Creosoted ties have remained sound after 22 years' exposure. The creosote protects the spikes from rusting. (g) Spruce and tamarack, owing to their irregular density, are unsuitable for creosoting. (h) Creosote renders wood stiffer and slightly more brittle. In hot weather it exudes to some extent and discolors the wood. Its smell excludes it from dwellings. (i) It does not wash out from the wood, but often fails to penetrate the heart-wood. Then, if any sap remains, decay begins at the center. See end of Art 1 (a). Burnettizing the cen of the stick (see Art 7) and using a coating of creosote outside, has long been suggested as the best possible method. It is the principal feature of the **Allardyce process.** This is cheaper than thorough creosoting. In the **Rütgers process,** which has been successfully employed for ties in Germany since 1874, the creosote and a solution of zinc chloride are injected simultaneously. (j) In the **creo-resinate process** * the preservative fluid consists of creosote 38 per cent, formaldehyde 2 per cent, and melted resin 60 per cent.

Art. 5. (a) **Mineral solutions** are inferior to creosote, even on land; and useless in running water or against sea-worms; but they approximately double the life of inferior timber under ordinary land exposures; and their cheapness permits their use where that of creosote is too expensive. (b) They render wood harder; and brittle if the solution is too strong. They are liable to be washed out by rain, etc. Hence the outer wood decays first. See Art 4 (i) Art 8 (b) (c) (d). (c) A committee of the American Soc of Civ Engrs,† after collating a large number of experiments, recommended **Burnettizing** (Art 7) **for damp exposure,** as that of cross ties, damp floors, etc; and **Kyanizing** (Art 6) **for comparatively dry situations** with exposure to air and sun-light, as in bridge timbers, for which it is better suited than Burnettizing because it seems to weaken wood less. In such exposures it preserves wood sometimes for 20 to 30 years.

Art. 6. (a) **Kyanizing** consists in steeping the wood in a solution of 1 lb of bi-chloride of mercury (corrosive sublimate) in 100 lbs of water. (b) It is usual to allow the wood to soak a day for each inch of the thickness or least dimension of the piece, and one day in addition, whatever the size. (c) Gen'l Cram found the process very **unhealthy,** "salivating all the men"; but Mr. J. B. Francis, at Lowell, and Mr. H. Bissell, of the Eastern R R of Mass, had little or no trouble in this respect. The sublimate, however, which is very poisonous, is apt to effloresce, and the use of the timber is thus rendered dangerous. (d) The process is valuable for timber placed in moderately damp situations, but the salt is liable to be washed out by running water. Kyanized spruce fence posts, planted 4 ft in the ground, at Lowell, Mass, in 1850, were examined in 1891, and most of them were found very sound both above and below the surface of the ground.

Art. 7. (a) **Burnettizing** consists in immersing the wood for several hours in a solution of 2 lbs **chloride of zinc** in 100 lbs of water, under a pres of from 100 to 300 lbs per sq inch.

Art. 8. Other preventives. (a) Steeping in a solution of **sulphate of copper (blue vitriol)** has been extensively used, but does not seem to have been permanently successful. The blue vitriol washes out readily. (b) In the **Barschall or Hasselmann process,**‡ introduced in Germany in 1887, in the U S in 1899, the wood is boiled, at a temperature from 212° to 284° Fahr. and under a pressure of from 15 to 45 lbs per sq inch, in a solution of iron, copper and aluminum sulphates and "Kainit," a sulphate of magnesia and potash, mined at Stassfurt, Germany. The solution is said to carry off the sap (timber being more readily treated by this process when green than when seasoned), while the copper destroys the fungi, and the iron forms an insoluble compound with the cellulose or woody fibre. It is claimed that the process greatly hardens the wood, especially the softer varieties, rendering them suitable for ties, without impairing their strength, elasticity or pliability. (c) The **Wellhouse process** injects first a solution of chloride of zinc with glue, and then one of tannin (both under pressure), in order to diminish the subsequent washing out of the chloride. In a later modification, the zinc, glue and tannin solutions are injected separately. Several millions of ties have been treated in this way. The

† See Transactions, Am Soc C E, July, Aug and Sept, 1885.
‡ Railroad Gazette, February 9, 1900.

process is not recommended for sub-aqueous use. (d) Processes in which the wood is treated by **painting or soaking*** are: Carbolineum Americs (C. A. Wood Preserver) and Carbolineum Avenarius (Tar-oil, chlorine, etc), Ligni Salvor (Tar-oil, etc), Woodiline and Spirittine (chemical solutions) and a distillate of pine used by the Pennsylvania Railroad Co. for car work. (e) Fence-posts etc seem to be preserved, to some extent, by having only their lower ends dipped in **tar** well boiled to remove the ammonia, which last is destructive to wood. The upper end must be left untarred to let the sap evaporate. (f) Attempts at wood preservation by means of **vapor of creosote** etc have proved failures. (g) While wood remains thoroughly saturated with **petroleum** it does not decay. But unless the supply is kept up the oil evaporates and leaves the wood unprotected. (h) Cottonwood ties laid upon a **soil** containing about 2 per cent carbonate of lime, 1 per cent salt and 0.5 per cent each of potash and oxide of iron, on the Union Pacific R. R. in 1868, were found in 1882 "as sound and a good deal harder than when first laid," although such ties in other soils lasted but from 2 to 5 years. (i) The use of solutions of **lime** and of **salt**; and **charring** the surface; are sometimes found useful in damp situations.

* See Report by O. Chanute to the American Railway Engineering and Maintenance of Way Association, March, 1901.

Art. 4. Ultimate average tensile or cohesive strength of Timber,

Being the least weights in pounds which, if attached to the lower end of a vert rod one inch square, firmly upheld at its upper end, would break it by tearing it apart. For large timbers we recommend to reduce these constants $\frac{1}{4}$ to $\frac{1}{3}$ part.

The strengths in all these tables may readily be one third part more or less than our averages.	Lbs per sq. inch		Lbs per sq. inch.
Alder	14000	Mahogany, Honduras	8000
Ash, English	16000	" Spanish	16000
" American (author) abt.	16500	Mangrove, white, Bermuda	10000

Hickory, Amer'n	11000	Yew	8000
Lignum Vitæ, Amer'n	11000		
Lancewood	23000	**Across the grain**, Oak	2300
Larch, Scotch	7000	" " " Poplar	1800
Locust	18000	" " " Larch, 900 to	1700
Maple	10000	" " " Fir, & Pines	550

THESE ARE AVERAGES. The strengths vary much with the age of the tree; the locality of its growth; whether the piece is from the center, or from the outer portions of the tree; the degree of seasoning; straightness of grain; knots, &c, &c. Also, inasmuch as the constants are deduced from experiments with good specimens of small size, whereas large beams are almost invariably more or less defective from knots, crookedness of fibre, &c, it is advisable in practice to reduce these constants as recommended above.

* **Effect of Tapping Trees for Turpentine.** Preliminary experiments by the Forestry Division of the U. S Department of Agriculture upon long-leaf pine from Alabama indicate that (contrary to the generally received impression) "turpentine timber," *i. e* the timber of trees that have been "boxed" (robbed of their turpentine), while it has slightly less tensile and shearing strength, is from 20 to 30 per cent. stronger in compression (whether with or across the grain) and under transverse strain. In the "turpentine timber," however, the resin collects in spots, gumming the tools, and thus rendering the timber harder to work than that of trees which have not been deprived of their turpentine. The specimens tested were taken mostly at heights of from 7 to 33 feet above ground. (Circular No. 8. Issued 1892.) Boxed and unboxed timber are frequently called "bled" and "unbled" respectively.

Art. 1. Compressive strengths of American woods, *when slowly and carefully seasoned.* Approximate averages deduced from many experiments made with the U S Govt testing machine at Watertown, Mass, by Mr. S. P. Sharples, for the census of 1880. **Seasoned woods** resist crushing much better than green ones; in many cases, twice as well. This must be allowed for when building bridges, &c, of timber recently cut. Different specimens of the same wood vary greatly; frequently as 5 to 8, 9, or more.

The strengths in all these tables may readily vary as much as one-third part more or less than our average.	Endwise.* lbs per sq in.	Sidewise.¶ lbs per sq in.

Hence it appears that *seasoned* white and yellow pines, spruce, and ordinary oaks which are the woods most employed in the United States for bridges, roofs, etc., crush endwise with from 5000 to 7000 lbs per sq inch, ***in short blocks;*** average, 6000

But it is well to bear in mind that in practice perfectly equable pressure is rarely secured. In a few trials on sidewise compression, with fairly seasoned white pine blocks, 6 ins high, 5 ins long, and 2 ins wide, we found that under an equally distributed pressure of 5000 lbs total or 500 lbs per sq inch, they compressed about from $\frac{1}{8}$ to $\frac{1}{4}$ inch; which is equal to from $\frac{1}{4}$ to $\frac{1}{2}$ inch per foot of height; or from $\frac{1}{24}$ to $\frac{1}{48}$ of the height; the mean being about $\frac{3}{8}$ inch to a foot, or $\frac{1}{32}$ of the height. Under 10000 lbs total, or 1000 lbs per sq inch, they split badly; and in some cases large pieces flew off.

The tensile or cohesive strengths of pine and oak average about 10000 lbs per sq inch, or $\frac{1}{2}$ as much as average cast-iron, or nearly double their resistance to crushing. The tensile strength does not change with the length of the piece; so that in practice we may take its safe strain at from 1000 to 2000 lbs per sq inch, depending upon the character of the structure, &c., without regard to the length, except when this is so great that two or more pieces have to be spliced together to make it; thus weakening the piece very much.

* Specimens 4 centimetres (1.57 inch) square, 32 centimetres (12.6 ins) long. When the length exceeds 10 times the least side, see Wooden Pillars.

¶ Specimens 4 centimetres (1.57 inch) square, 16 centimetres (6.3 ins) long; laid upon platform of testing machine. Pressure applied at their mid-length, by means of an iron punch 4 centimetres square, or just covering the entire width of the specimen, and one-fourth of its length. The first column (headed ".01") gives the loads producing an indentation of .01 inch. The second column (headed ".1") gives those producing an indentation of .1 inch.

Table of safe quiescent loads for horizontal rectangular beams of white pine or spruce, one inch broad. supported at both ends, and loaded at the center; together with their deflections under said loads.

The safe load is here one-sixth of the breaking load.

For the neat loads, deduct ½ the wt of the beam itself. The *deflections*, however, are the *actual* ones; the wts of the beams having been introduced in calculating them.

Loads applied suddenly will double the deflections in the table; as when, for instance, if a load is held by hand, just *touching* a beam, the hold should be *suddenly* loosed.

Caution. Inasmuch as this table was based upon well seasoned, straight grained pieces, free from knots, and other defects, we must not in practice take more than about two-thirds of the loads in the table for a safety of 6 in ordinary building timber of fair quality; and with these reduced loads should not reduce the deflections.

Observe also that our table is for safe **center** loads, but it is plain that in practice we cannot always apply the term in its utmost strictness; otherwise the load would have to be sustained by a mere knife-edge, at the *very* center of the beam. Now, in the case of Rem. p. 1140, if we attempted to sustain the center load of 6075 lbs upon such a knife-edge, it would at once cut the beam in two. If we even applied it along 3 or 4 ins of the length, it would cut into it, and we should not have a safety of 6 against crushing the top of the beam until as in the case of the ends we distributed the load along full 46 ins of length, or about 32 ins for a safety of 4.

The safe load is here ⅙ of the breakg one; and the last at 450 lbs at the center of a beam 1 inch square, and 1 foot clear length between its supports. For mere temporary purposes, ½ part may be added to the loads in the table, thus making them equal to the ¼ of the breakg load. But in important structures, subject to vibration, ¼ part should be deducted from the tabular loads, thus reducing them to ⅛ of the breaking load. This is especially necessary if the timber is not well seasoned.

With the safe loads in this table a beam may bend too much for many practical purposes. When this is the case, we may, by reducing the loads, reduce the deflections in nearly the same proportion.

All the loads in the Table are superabundantly **safe against shearing. Against crushing at the ends,** &c, see "**Cautions**" below the Table.

White oak, and best Southern pitch pine will bear loads ¼ greater.

For cast iron, mult the **loads** in the table by 4.5; and for **wrought** by 5.3 For these new loads, mult the **defs** by .4 for cast; and by 3 for wrought.

If the load is equally distributed over the span, it may be twice as great as the center one, and the defs will be 1¼ times those in the table. **If the loads in the table** be equally distributed along the whole beam, the defs will be but five-eighths as great as those in the table. When more accuracy is reqd, half the wt of the beam itself must be deduc'ed from the center load; and the whole of it from an equally distributed load. The wt of the beam, in the last column, supposes the wood to be but moderately seasoned, and therefore to weigh 28.8 lbs per cub ft.

Uses of the foregoing table. Ex. 1. What must be the breadth of a hor rect beam of wh pine, 18 ins deep, supported at both ends, and of 20 ft clear length between its supports, to bear safely a load of 5 tons, or 11200 lbs at its center? Here, opposite the depth of 18 ins in the table, and in the column of 20 feet lengths, we find that a beam 1 inch thick will bear 1215 lbs; consequently, $\frac{11200}{1215} = 9.22$ ins, the reqd breadth; for the strength is in the same proportion as the breadth

Ex. 2. What will be the safe load at the center of a joist of white pine, 18 ft long, 3 ins broad, and 12 ins deep? Here, in the col for 18 ft, and opposite 12 ins in depth, we find the safe load for a breadth of 1 inch to be 600 lbs; consequently, $600 \times 3 =$ 1800 lbs, the load reqd.

Rem. Cautions in the use of the above table. For instance, in placing very heavy loads upon short, but deep and strong beams, we must take care that the beams rest for a sufficient dist on their supports to prevent all danger from *crushing* at the ends. Thus, if we place a load of 6075 lbs at the center of a beam of 4 feet span, 18 ins deep, and only 1 inch thick, each end of the beam sustains a vert crushing force of $\frac{6075}{2} = 3037$ lbs, and that **sidewise of the grain,** in which position average white pine, spruce, and hemlock crush under about 800 lbs per sq inch, and do not have a safety of 6 until the pressure is reduced to about 133 lbs per sq inch. Therefore our beam, in order to have a safety of 6 against crushing at its ends, must rest on each support $3037 \div 133 = 23$ sq ins; or for a safety of 4 nearly 16 sq ins. When a pressure is equally distributed sidewise (that is, at right angles to the general direction of the fibres) over the entire pressed surface of a block or beam (to ensure which, the opposite surface must be supported throughout its entire length) the resulting compression might readily escape detection unless actually measured. But when a considerable pressure is applied to only a portion of the surface, as of caps and sills where in contact with the heads and feet of posts, or at the ends of loaded joists or girders, the compression becomes evident to the eye, because the pressed parts sink below the unpressed ones, in consequence of the bending or breaking of the adjacent fibres. What in the first case (especially if slight) would be called **compression**, would

in the second be called **crushing**; even when neither might be so great as to be unsafe.

Owing to the resistance which said adjacent fibres oppose to being bent or broken, it is plain that a given pressure **per sq inch**, or **per sq foot**, &c., will cause somewhat less compression or crushing when applied to only a part of a surface, than when to the whole of it.

The writer has seen 40 half seasoned hemlock posts, each 12 ins square, footing at intervals of 5 ft from center to center, upon similar 12 × 12 inch hemlock sills, to which they were tenoned, and which rested throughout their entire length on stone steps. Each post was gradually loaded with 32 tons or equal to say 500 lbs per sq inch, and their feet all crushed into the sills from ¼ to ½ inch. Their heads crushed into the caps to the same extent. **In practice** the pressure at the heads and feet of posts is rarely if ever perfectly equable, and the same remark applies to the ends of loaded joists, girders, &c., in which a slight bending will throw an excess of pressure upon the inner edges of their supports.

Art. 31. Table of greatest center loads for horizontal rectangular beams of white or yellow pine, or of spruce, 1 inch broad, supported at both ends, and required not to bend more than $\frac{1}{40}$ inch per foot of clear span, or $\frac{1}{480}$ part of the entire clear span. In practice, to allow for knots, &c, take only ⅔ rds. The loads in this table include the weight of the clear beam itself. 625 of which (or ⅝ of which) must be deducted from the tabular loads to get the neat load, when the beam is loaded at its center. When uniformly loaded, the loads will be 1 6 times as great as those in this table; but in that case the weight of the entire clear beam must be deducted. In practice this deduction need rarely be made.

On this side of the dark lines, the safe loads of table, p 1139, would not bend the wooden beams as much as $\frac{1}{480}$ of their clear span.

Iron and Steel.

Average cast iron, with the same safe def will bear about 11½ as much as common yellow or white pine, or spruce; and wrought iron 19 times as much. The same proportion of the weight of the beam itself must, however, be deducted as stated above for wood. Average steel 29 times as much as pine.

WOODEN COLUMNS.

See columns in general, pp 495 &c.
For steel and iron columns, see pp 1189 &c.

1. The strengths of wooden columns increase with the degree of **seasoning.** As in other columns, **eccentricity of loading** greatly diminishes the strength, and it is seldom possible to determine closely the degree of eccentricity.

2. Let all stresses be in pounds and all dimensions in inches, and let

P = total load (supposed axial) on col ;	r = least rad of gyr of cross sec ;
a = area of cross section of col ;	D = diam, or least side, of cross sec;
p = P/a = avge unit load on col ;	L = length of column ;
s = max unit stress in any cross sec ;	K = L/r = length ratio, or slenderness of col, in terms of r ;
s_e = unit stress at elastic limit ;	k = L/D = length ratio, or slenderness of col, in terms of D.
s_s = max unit stress in a short col ;	

3. Wooden columns are nearly always **solid and rectangular,** and most frequently **square,** in cross section. Hence, instead of the least radius of gyration, r, it is convenient to use the least side, D. For values of D/r and of $(D/r)^2$, see pp 353 *a*, 353 *b*.

4. In solid square or rectangular columns,

$$D = \sqrt{12}\, r ; \quad D^2 = 12\, r^2 .$$

For the slenderness, we have $k = L/D = L/(\sqrt{12}\, r) = K/\sqrt{12}$; and $k^2 = K^2/12$; $K^2 = 12\, k^2$.

Hence, the **Rankine and straight-line formulas** become, respectively :

$$\textbf{Rankine formula ; } p = \frac{P}{a} = \frac{s}{1 + m K^2} = \frac{s}{1 + 12 m k^2} .$$

$$\textbf{Straight-line formula ; } p = P/a = s_s - c\, K = s_s - k\, c\, \sqrt{12},$$

where, as in ¶ 2:

p = mean unit load on column ; **m, c** = coefficients ;
s = max unit stress in cross section ;
s_s = max unit stress in cross section for short blocks ;
K = L/r = unsupported length ÷ least *radius of gyration* ;
k = L/D = unsupported length ÷ least *side* ;
F = safety factor = ultimate load ÷ permissible load.

5. The table, pp 1144-5, gives **values commonly used,** with these two formulas, for the coefficients in connection with wooden columns. For list of authorities quoted, see above
See diagram, Fig 1, of values of p/s.

* **P** = total load, lbs; **a** = cross section area, sq ins; **k** = L/D = length / least side. *Nos.* in ( ) refer to list, p 1143. *Letters* in ( ) refer to **notes,** p 1146.

Notes on table, pp 1144-5.

where, as in ¶ 2:

p = mean unit load on column; **m. c** = coefficients;
s = max unit stress in cross section,
s_u = max. unit stress in cross section for short blocks;
K = L/r = unsupported length ÷ least *radius of gyration*;
k = L/D = unsupported length ÷ least *side*.
F = safety factor = ultimate load ÷ permissible load.

(**a**) **Smith.** Flat ends, firmly fixed For $k \not> 25$, $F = 5$, for $k > 25$, $F = \sqrt{k}$. (F = ult ÷ permissible load)

1. Green, half-seasoned "Good merchantable lumber."
2. Selected, reasonably straight, air-seasoned under cover 2 yrs and over.
3. Avge sticks, cut from lumber in open air service 4 yrs or over.

Coeffs based upon 1200 tests of full-sized columns, 1861-2 To guard against deterioration and defects, Mr Smith recommended the *third* set of values. $s = 5000$; $1/(12\ m) = 250$.

(**b**) **Burr.** For good avge lumber. F = ult ÷ permiss load For railway structures, $F = 8$, for temporary structures, under static loads, $F = 4$.

(**d**) **Forestry.** Square columns. $F = 7$. $1/(12\ m) = 700 + 15\ k$; hence $p = P/a = s \cdot \frac{700 + 15\ k}{700 + 15\ k + k^2}$. To allow for weathering, add 0.5 inch to each cross-sectional dimension required by formula.

(**e**) **Cambria.** See note (d) Forestry, above.

	Yellow pine F	Others F
Class A. Moisture 18%. Freely exposed (trestles, uncovered bridges, etc),	5.0	5.0
" B. " 15%. Roofed, not side-sheltered (covered bridges, etc),	4.3	4.5
" C. " 12%. Enclosed but not heated,	3.6	4.2
" D. " 10%. Enclosed and heated,	3.2	4.0

(**f**) **Worcester.**

	$k \not> 50$ p	$k \not> 10$ p
Long-leaf pine	600	1000
Spruce, white pine	300	700
White oak	600	1000
Hemlock	250	650

For each increase of 10, in k, deduct 100 from p. See Columns in General p 498 *b*, ¶ 34.

(**g**) **Boston.**

	$k \not> 30$ p	y	$k \not> 10$ p
Long-leaf pine	700	50	900
Spruce, white pine	190	35	630
White oak	330	45	510

For each increase of 5, in k, deduct y from p.

(**h**) **Carnegie and Passaic.** For long posts, $F = 5$; for short posts, $F = 4$. F = ult ÷ permiss load.

6. J. B. Johnson, (10) for his **parabolic formula** (Columns in General, ¶ 28, p 498).

$$p = \frac{P}{a} = s_e - \frac{s_e^2}{q\ \pi^2 E} K^2 = s_e - 12\ c_p\ k^2,$$

gives, as **ultimate** values:

k = length ÷ least *side*;
s_e = elastic limit.

	(10) p 367, flat ends $k \not> 60$ s_e	$12\ c_p$	(10) pp 683–4. Dry s_e	$12\ c_p$	Partially seasoned s_e	$12\ c_p$
Long leaf yellow pine	4000	0.8	6000	1.5	4500	1.0
Short leaf yellow pine	3300	0.7	......	....		
White pine	2500	0.6	3600	0.72	2500	0.5
White oak	3500	0.8	....	.....	....	....

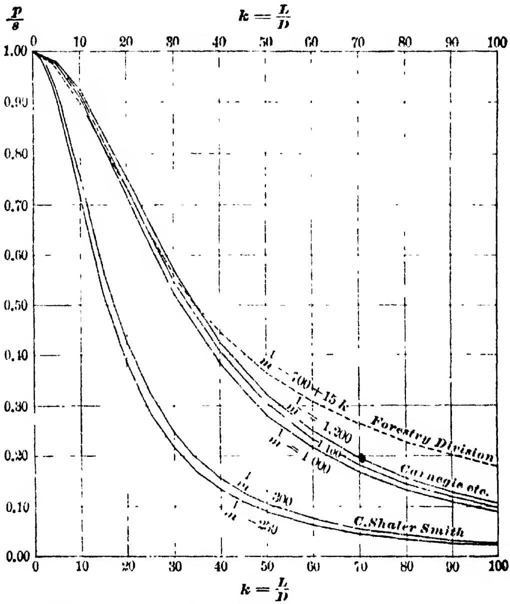

Fig. 1. Values of p/s. See Iron and Steel Cols, p 1197 ¶ 21

FORMULAS AND EXPERIMENTS.

7. The accompanying diagram, Fig 2, shows a comparison of formulas for, and experiments upon, **yellow pine columns**, as follows:

p = mean unit load on column; **k** = length ÷ least *side*.

Formulas.

Ultimate.

1. Rankine; C Shaler Smith .... $p = 5400 \div (1 + 0.004\,k^2)$
2. Rankine; C Shaler Smith .... $p = 8200 \div (1 + 0.00333\,k^2)$
3. Rankine; C. Shaler Smith .... $p = 5000 \div (1 + 0.004k^2)$
4. Rankine; U. S. Division of Forestry $p = 7000 \times \dfrac{700 + 15\,k}{700 + 15\,k + k^2}$
5. Parabolic; J. B. Johnson, p 367 ...... $p = 4000 - 0.8\,k^2$
6. Parabolic; J. B. Johnson, p 683 .... $p = 4500 - 1\,0\,k^2$, Partially seasoned.
7. Parabolic; J. B. Johnson, p 684 .... $p = 6000 - 1\,5\,k^2$, Dry.
8. Straight-line; Wm. H. Burr, . $k < 20$, $p = 4400 - 0$
   $k = 20$ to 60, $p = 5800 - 70\,k$
9. Straight-line; Jas. H Stanwood, $k < 20$, $p = 4250 - 0$
   $k > 20$, $p = 4250 - 43\tfrac{1}{8}\,k$
10. Stepped; Edward F. Ely,

k =	0 to 15,	to 30,	to 40,	to 45,	to 50,	to 60
p =	4,000	3,500	3,000	2,500	2,000,	1,500

Permissible.

8 Baltimore & Ohio R R Co,
  ($k_{max} = 40$) For $k < 17$, $p = 900 - 0$
  For $k > 17$, $p = 1200 - 18\,k$

9. Boston building code, ...

k =	0–10	10–15	15–20	20–25	25–30
($k_{max} = 30$) .... p =	900	850	800	750	700

10. New York buildigg code ($k_{max} = 30$) $p = 1000 - 18\,k$.

Experiments.

Ultimate.

✝ Average of 12 endwise compression tests (11) pp 54 etc, on **short yellow pine blocks**, from 1.5 × 1.5 ins, 3 ins long, to 10 × 10 ins, 20 ins long; k from 2 to 3.75, average = 2.36; p, average, 8,105 lbs per sq inch; in 10 of the tests, p ranged from 7,394 to 10,250 lbs per sq inch. The other 2 were

1.5 × 1.5 ins, 3 ins long, $p = 5533$; failed at knots.
1.5 × 1.5 ins, 3 ins long, $p = 6355$; season crack, nearly dividg spec'n.

● Tests of yellow pine posts, 5.5 ins square, 80 to 320 ins long, at Watertown Arsenal, (12) pp 377–8.

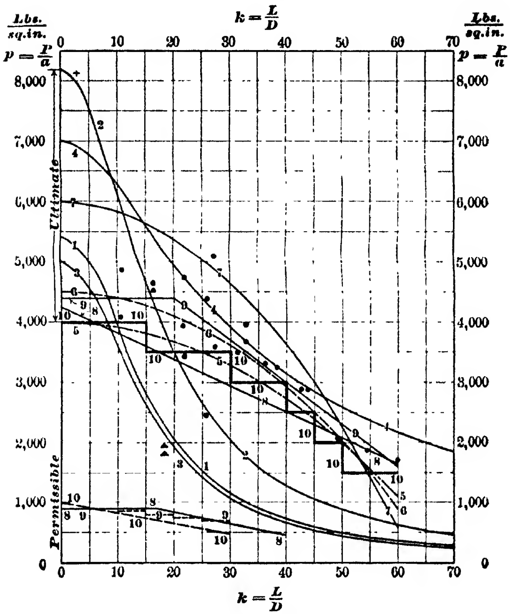
Each item is the average of from 2 to 4 tests.

Columns, each composed of two or more sticks, bolted together, showed, in general, no greater strength, in pounds per square inch, than did the single sticks of which they were built up.

▲ Riga and Dantzic firs, 13 ins sq, 20 ft long. Kirkaldy.

Mr. Smith's formulas represent his 1200 tests of full-size columns.

The formula of the U. S. Division of Forestry closely represents the results of 50 tests by that Division.



$k = \frac{L}{D}$
$\frac{Lbs.}{sq.in.}$
$p = \frac{P}{a}$

Fig. 2.

REQUIREMENTS FOR IRON AND STEEL.

(See also Bridge Specifications.)

Digest of Specifications adopted, subject to letter ballot, at 4th Annual Meeting of the **American Section** of the **International Association for Testing Materials,** June 29, 1901 Adopted by letter ballot, August, 1901, except wrought iron, on which action was deferred

Process of Manufacture.

Wrought iron; puddled, charcoal hearth, or rolled from fagots or piles made from wrought iron scrap, alone or with muck bar added.

Steel castings. Open-hearth, crucible or Bessemer process.

Steel forgings. Open-hearth, crucible or Bessemer process.

Steel Rails. Bessemer or open-hearth. Ingots shall be kept vertical in pit-heating furnaces. No bled ingots shall be used. Sufficient material shall be discarded from the tops of the ingots to insure sound rails.

Steel Splice Bars Bessemer or open-hearth.

Boiler Plate and Rivet Steel. Open-hearth.

Structural steel for bridges and ships. Open-hearth.

Structural steel for buildings. Open-hearth or Bessemer.

Test Pieces.

For flat plates, the specimen shown in Fig. J shall be used.

For large rounds, test specimen as shown in Fig. K. The center of the specimen shall be half way between the center, and the outside of the round.

Whenever possible, iron shall be tested in full size, as rolled.

Test specimens shall be cut from bar as rolled.

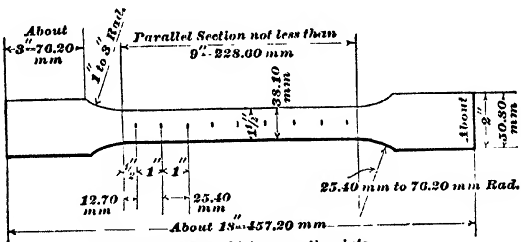

Fig. J.

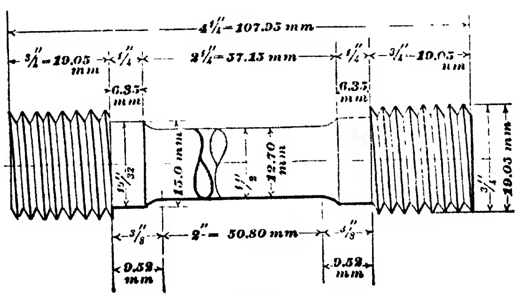

Fig. K.

Tests.

Nicking tests. The specimen shall be slightly and evenly nicked on one side, and bent back at this point through an angle of 180° by a succession of light blows.

Hot bending tests. Specimens shall be heated to a bright red, and bent by pressure or by a succession of light blows and without hammering on bend.

Cold bending tests. Specimen to be bent by pressure or by a succession of light blows.

Yield point. The yield point shall be determined by careful observation of the drop of the beam or halt in the gage of the testing machine

Drop tests. The drop testing machine for rails shall have a tup of 2000 pounds, the striking face of which shall have a radius of not more than 5 ins; and the test rail, not more than 6 feet long, shall be placed head upwards on solid supports 3 ft apart. The anvil block shall weigh at least 20,000 lbs, and the supports shall be a part of, or firmly secured to, the anvil. Height of drop from 15 ft for 45 lb rail to 19 ft for 85 lb and over. One test piece shall be selected from every fifth blow.

Homogeneity tests for fire box steel. A portion of the broken tensile test specimen is either nicked or grooved $\frac{1}{16}$ inch deep, in three places about 2 ins apart and on opposite sides. It is then clamped in a vise and broken off, by light hammer blows, bending away from each groove in succession. The specimen must not show any single seam or cavity more than $\frac{1}{4}$ inch long.

Notes to table, pp 1152 and 1153.

(a) To be bent flat.

(b) Specimen to be bent about a bar of diameter equal to its own diameter or thickness.

(c) Specimen to be bent about a bar twice its diameter.

(d) Elongation, min, per cent, in sections less than 0.654 lbs. per linear ft, grade A, 19, B, 15; C, 12

(e) Nicking test. Max per cent granular surface, grade A, 10; B, 10; C, 15.

(f) Hot bending test. Bar to be bent without cracking on outside of bend. To be bent flat in each grade; 180° in grades A and B, and sharply to 90° in C. Grade A, heated yellow and suddenly quenched in water between 80° and 90° F, to bend flat 180°. Also, heated bright red, split at end, and each part bent back 180°. Punched and drifted to hole at least 0.9 diam of rod or width of bar.

(g) Phosphorus, pieces for physical test, 0.05 for each grade.

(h) Sulphur, pieces for physical test, 0 05 for each grade.

(i) Bending. Specimen 1 inch × $\frac{1}{2}$ inch to bend cold around a diam of 1 inch without fracture on outside of bent portion.

(j) Bending. Specimen 1 inch × $\frac{1}{2}$ inch to bend cold, without fracture on outside of bent portion, around a diameter of $\frac{1}{2}$ inch.

(k) Same, around diam of $1\frac{1}{2}$ ins

(l) Same, around diam of $1\frac{1}{2}$ ins if not less than 20 ins diam; around a diam of 1 inch if less than 20 ins diam.

(m) Same, about a diameter of 1 inch.

(n) " " " " $\frac{1}{2}$ "

(o) " " " " 1 "

(p) Deduct 1 per cent for each $\frac{1}{8}$ inch in thickness above $\frac{3}{4}$ inch, and $2\frac{1}{2}$ per cent for each $\frac{1}{16}$ inch below $\frac{5}{16}$ inch.

(q) Bending. Rivet rounds to be tested of full size, as rolled. Plate specimens shall be $1\frac{1}{2}$ ins wide. For plates not over $\frac{3}{4}$ inch thick, the thickness shall be the same as that of the plate, and the specimen shall, where possible, have the natural rolled surface on two opposite sides. For plates thicker than $\frac{3}{4}$ inch, the specimen may be $\frac{1}{2}$ inch thick. Shall be subjected to both cold and quenched bending tests. For the quenched test, the material is to be heated to a light cherry red (as seen in the dark) and quenched in water of temperature between 80° and 90° Fahr. Samples shall bend flat without fracture on the outside of bent portion. Bending may be done by pressure or by blows.

(r) For pins, the elongation shall be 5 per cent less. Center of test specimen 1 inch from surface.

(s) Eye-bars shall be of medium steel. Full-sized tests shall show $12\frac{1}{2}$ per cent elongation in 15 ft of body. Min tensile strength, 55,000 lbs. per sq in. At least $\frac{2}{3}$ of eye-bars tested shall break in the body.

(t) Same as (q) but omitting quenching test.

(u) See Homogeneity Test, in text, above.

Digest of
"Manufacturers' Standard Specifications" for Steel,
as adopted by the **Association of American Steel Manufacturers,** Aug 9, 1895, and revised to Feb 6, 1903. In effect July 31, 1908

Words in parentheses, in Roman type, as (May be **open-hearth or Bessemer**), apply only to structural steel. Words in parentheses, in *italics*, as (*four*), (*two*), to be substituted for the preceding words (**Two**), (one), for special open-hearth plate and rivet steel. Otherwise, and except where especially stated, the provisions apply to both steels.

(May be **open-hearth or Bessemer.**)

"**Tests and inspections** shall be made at the place of manufacture prior to shipment."

Test pieces.

Standard test piece for sheared plates. See Fig J, p 1150.

Test pieces from other material, either as above or planed or turned parallel thruout length of piece.

In all cases two opposite sides of test piece to be **rolled surfaces** if possible.

"**Rivet rounds and small bars** shall be tested of full size as rolled."

"**Two** (*four*) **test pieces** shall be taken from each melt (or blow) of finished material, one (*two*) for tension and one (*two*) for bending; but in case either test develops flaws, or the tensile test piece breaks outside of the middle third of its gaged length, it may be discarded and another test piece substituted therefor."

"When material is to be **annealed or otherwise treated** before use, the specimen representing such material shall be similarly treated before testing." Otherwise, the material "shall be tested in the condition in which it comes from the rolls."

"Every finished piece of steel shall be **stamped** with the (blow or) melt number, (and steel for pins shall have the blow or melt number stamped on the ends). Rivet (and lacing) steel, (and small pieces for pin plates and stiffeners), may be shipped in bundles securely wired together, with the (blow or) melt number on a **metal tag** attached."

Maximum phosphorus and sulphur, per cent

	Phosphorus	Sulphur
Structural		
for buildings, train sheds, highway bridges, etc	0.10	..
for railway bridges	0.08	.
Special		
flange or boiler steel	0.06	0 04
extra soft and fire box steel....................	0 04	0.04

Mechanical Properties.

	Structural Steel			Special Steel		
	Rivet	Ry bridge	Medium	Extra soft*	Fire box	Flange or boiler
Bending test ‡ 180° without fracture on outside of bent portion to a diam =........	0	t	t	0†	0†	0†
Ult tensile strength in thousands of lbs per sq in	48 to 58	55 to 65	60 to 70	45 to 55	52 to 62	55 to 65
Elongation (for deductions etc see below)	1,400,000 ÷ ult strength			28%	26%	25%
Elastic Limit......................	Not less than half the ultimate strength					

*Boiler rivets to be of "extra soft" steel. †Cold or quench bends.

‡t=thickness of test piece.

Elongation, in rounds ⅝ in or less, measured in a length = 8 × diam of section tested; in other cases, measured in length of 8 ins. From the specified elongations; **deductions** to be made as follows on account of thickness: **for each increase** of ⅛ inch **above ¾ inch,** 1%, (min 20% for eye-bar material, 18% for other structural material): **for each decrease** of 1/16 inch below 5/16 inch, 2.5%: (for pins, 5%; elongation measured "on a test piece, the center of which shall be one inch from the surface of the bar.")

Percentage of allowed variation in weight or cross section of sheared plates.

When ordered to weight.

Weight per sq ft	< 12.5 lbs			≮ 12.5 lbs	
Width, ins	< 75	75 to 100	≮ 100	< 100	≮ 100
Variation, %	± 2.5	+ 5, − 3	+10, − 3	± 2.5	± 5

When ordered to gage. percentage of excess in rectangular plates. (Plates ≯ 0.01 inch light, considered up to gage.)
1 cu in rolled steel assumed = 0.2833 lb

Thickness ins.	Width, ins. < 50	50 to 70	> 70	< 75	75 to 100	100 to 115	> 115
⅛ to 5/32	10	15	20				
5/32 to 3/16	8.5	12.5	17				
3/16 to ¼	7	10	15				
¼				10	14	18	
5/16				8	12	16	
⅜				7	10	13	17
7/16				6	8	10	13
½				5	7	9	12
9/16				4.5	6.5	8.5	11
⅝				4	6	8	10
> ⅝				3.5	5	6.5	9

In other cases, a variation > 2.5% in weight or cross section will be sufficient cause for rejection.

Iron is weakened by extreme cold.

The belief (originating with Styff of Sweden) is gaining ground that iron and steel are not rendered *more brittle by intense cold,* but that the great number of breakages of rails, wheels, axles, &c, in winter, is owing to the more severe blows incident to the frozen and unyielding nature of the earth at that period of the year. But Sandberg's experiments show conclusively that although these metals may perhaps bear as much *steady* force, *gradually* applied, in winter as in summer, yet their resistance to *impulse*, or *sudden force*, is not more than ½ or ⅓ as great in severe cold; which renders them less flexible and less stretchy. It is probable that this fact does not receive as much attention as it should, in proportioning iron bridges, &c.

Some experiments with good wrought iron showed that even at 23° Fah, or only 9° colder than freezing point, there was a loss of strength of from 2½ to 4 per cent.

Malleable Cast Iron. Experiments by Mr. D L. Barnes, of Chicago, on a large number of samples of a single make of "malleable" cast iron, gave in most cases tensile strengths ranging from 21000 to 32000 lbs. per square inch, with an average of about 28000 lbs. The higher figures were obtained generally with the smallest bars (about 3 × ¼ inch) and the lower with the largest bars (about 3 × 1 inch) Pieces planed on all four sides averaged only about 24000 lbs. per square inch. This may explain the difference in favor of the smaller sections, in which the original "shell" forms a larger portion of the whole cross section.

CAST IRON.

Tensile strength	14,000 to 20,000 lbs *	per sq inch
Compressive strength (average about 100,000)	90,000 to 130,000 "	" "
Transverse strength, bar 1 in sq, 1 ft span, center load 2500 lbs. Deflection, minimum, 0.15 inch.		
Elastic limit about	6,000 lbs	per sq inch
Modulus of Elasticity "	15,000,000 "	" "

Specifications.

Tensile strength.

Bureau of Water, Philadelphia	16,000 to 20,000 lbs	per sq inch
Water Department, St. Louis, Mo	18,000 "	" "

Transverse strength.

Bureau of Water, Philadelphia.

1 in sq, 56 ins span, center load 500 lbs.

1 in sq, 36 ins span, " " 750 lbs. Deflection, minimum, 0.4 to 0.6 in.

Water Department, St. Louis, Mo.

3 in × ½ in (laid flat) 18 ins span, center load 1000 to 1250 lbs. Minimum deflection 0.3 to ⅝ inch.

Weight of Cast Iron.

Assuming 450 lbs per cub ft, specific gravity 7.2, a cub inch weighs 0.2604+ lbs; and a pound contains 3.83995+ cub ins.

Table, page 875: D = thickness or diameter, in inches.

Wt. of plate, 1 ft square, in lbs	$= 37.5\ D$ (Exact)	$\text{Log } W = 1.574\ 0313 + \text{Log } D$
" " sq bar, 1 ft long, in lbs	$= 3.125\ D^2$ (Exact)	$\text{Log } W = 0.494\ 8500 + 2 \text{Log } D$
" " rd bar, 1 ft long, in lbs	$= 2.45437\ D^2$	$\text{Log } W = 0.389\ 9400 + 2 \text{Log } D$
" " ball, in lbs	$= 0.136354\ D^3$	$\text{Log } W = \bar{1}.134\ 6551 + 3 \text{Log } D$

Weight of a spherical shell = weight of ball having outer diam of shell *minus* weight of ball having its inner diam.

Weight of pattern. A casting weighs 20 × weight of pattern of perfectly dry white pine. If not perfectly dry, although well seasoned, for 20, substitute 19 or 18.

For lead, at 700 lbs per cub ft, multiply weight of cast iron by 1.555---;
For copper, at 550 lbs, multiply by 1.222---;
For brass, at 500 lbs, multiply by 1.111---;
For wrought iron, at 485 lbs, multiply by 1.0777---;
For tin, at 460 lbs, multiply by 1.022---;
Zinc, at 450 lbs = cast iron.

* High grade irons may reach 30,000 to 40,000 lbs per sq inch, tensile.

TABLE OF WEIGHT OF CAST IRON.

At 450 lbs per cubic foot; specific gravity, 7.2.

D = Thickness or diameter, in inches. For equivalents in feet, see p 221.

WEIGHT OF CAST-IRON PIPES per running foot.

Assuming the weight of cast-iron at 450 lbs per cub ft, or .2604 lb per cub inch. No allowance is here made for the spigot and faucet-joints used in water-pipes. As these are now commonly made, they add to the weight of each length or section of pipe of any size, about as much as that of 8 inches in length of the plain pipe as given in the table.

For lead-pipe mult by 1.6, **copper,** mult by 1.2; **brass,** add 1-7th; **welded iron,** mult by 1.0667, or add one fifteenth part.

For warming buildings by steam it usually suffices to allow 1 sq ft of cast or wrought pipe surface for each 120 cub ft of space to be warmed; and 1 cub ft of boiler for each 2000 cub ft of such space.

Table of Weight of WROUGHT IRON and STEEL.

At 485 lbs per cubic foot; specific gravity, 7.76. See page 1161.

D = Thickness or diameter, in inches. For equivalents in feet, see p 221.

Weight of 1 ft in length of FLAT ROLLED IRON, at 480 lbs per cubic foot. For cast iron, deduct $\frac{1}{16}$ part; for steel, add $\frac{1}{48}$; for copper, add $\frac{1}{7}$; for cast brass, add $\frac{1}{13}$; for lead, add ½; for zinc, deduct $\frac{1}{12}$.

Weight of Wrought Iron and Steel.

Assuming 485 lbs. per cub ft,* specific gravity, 7.76; a cubic inch weighs 0.28067 lbs; and a pound contains 3.5629 cubic inches.

Table, page 1159: D = thickness or diameter, in inches.

Wt. of plate, 1 ft square, in lbs,	$= 40.4167\ D$;	$\text{Log } W = 1.606\ 5605 + \text{Log } D$
" " sq bar, 1 ft long, in lbs,	$= 3.36806\ D^2$;	$\text{Log } W = 0.527\ 3792 + 2 \text{ Log } D$
" " rd bar, 1 ft long, in lbs,	$= 2.64527\ D^2$;	$\text{Log } W = 0.422\ 4693 + 2 \text{ Log } D$
" " ball, in lbs,	$= 0.146959\ D^3$;	$\text{Log } W = \bar{1}.167\ 1966 + 3 \text{ Log } D$

Weight of a spherical shell = {weight of ball having outer diameter of shell} − {weight of ball having inner diameter of shell.

Weights of equal masses.

For lead,	at 700 lbs per cub ft: weight = 1.44 ×	weight of wrought iron
For copper,	" 550 " " " " = 1.13 ×	
For brass,	" 500 " " " " = 1.03 ×	
For tin,	" 460 " " " " = 0.948 ×	
For zinc or cast iron,	" 450 " " " " = 0.928 ×	

*Very pure soft wrought iron weighs from 488 to 492 lbs per cubic foot; average rolled iron about 480. At 480 lbs, a bar 1 inch square weighs exactly 10 lbs per yard = 3⅓ lbs per foot.

Weights per square foot of **galvanized sheet iron.** Standard list adopted by the American Galvanized Iron Ass'n, at Pittsburgh, April, 1884.

The galvanizing is simply a thin film of zinc on both sides of the sheet, as in what is known as "tinned plates," or "tin," which are in reality sheet iron similarly coated with tin. Zinc like tin, resists corrosion from ordinary atmospheric influences, much better than iron, and hence the use of these metals as a protection to the iron. A well galvanized roof, of a good pitch, will suffer but little from 5 to 6 years exposure without being painted. It will then take paint readily, and should be painted It is better, however, always to paint tin ones at once.

Paint does not adhere well to new zinc, and this is the principal reason why new galvanized roofs are not painted; but this may be remedied by first brushing the zinc over with the following One part of chloride of copper, 1 part nitrate of copper, 1 part of sal-ammoniac Dissolve in 64 parts of water. Then add 1 part of commercial hydrochloric acid. When brushed with this solution, the zinc turns black, dries within 12 to 24 hours, and may then be painted.

Paint of some mineral oxide of a brown color is generally used, one coat being applied to both sides in the shop; and the other after being put on the roof. Repainting every 3 or 4 years will suffice afterward Ungalvanized iron (called BLACK IRON, for distinction) is also very enduring for roofs, if well painted every 1 or 2 years. The chief advantage of galvanized roofing is that it does not require painting so often as the black. The galvanizing adds about ⅛ of a lb per square foot of surface, or about ½ lb per sq ft of sheet as coated on both sides; without regard to the thickness of the sheet. Paint for roofs should not have much *dryer*. See Painting.

The sulphurous fumes from coal are very corrosive of EITHER GALVANIZED OR BLACK IRON, as may be seen in shops, railroad bridges, or engine houses, roofed with either, if efficient means are not provided for carrying off the smoke; and the same with other metals THE ACID OF OAK TIMBER is said to destroy the zinc of galvanized iron

Flat iron is usually nailed upon a sheeting of boards; but the strength of corrugated iron obviates the necessity for this, and enables it to stretch 5 or 6 ft from purlin to purlin, without intermediate support. The corrugated sheets are riveted together on the roof, by rivets of galvanized wire about one eighth inch thick, 300 to a pound, well driven (so as to exclude rain) 3 or 4 inches apart, all around the edges. The rivet holes are first punched by machinery, so as to insure coincidence in the several sheets; and the rivets are driven by two men, one above, and one beneath the roof. For black iron, ungalvanized nails, boiled in linseed oil as a partial preservative from rust, are commonly used; as also in shingling or slating. Galvanized ones, however, would be better in all these cases, or even copper ones for slating because good slate endures much longer than either shingles or iron, and therefore it becomes true economy to use durable metals for fastening it. In none of these cases, however, are the nails fully exposed to the weather

The sheets of flat iron are put together by overlapping and FOLDING THE EDGES, much the same as shown by the fig page 1208, head Tin, the joints which run up and down the roof being the same as at *a a*, and the horizontal ones as at *t t*; except that inasmuch as these are not soldered in the iron sheets the joint is made about ¾ to 1 inch wide, instead of ⅜ inch, the better to provide against leaking. Cleats are used as in tin, with 2 nails to a cleat. The iron plates are best laid on sheeting boards; but in sheds, &c, are sometimes laid directly on rafters, not more than about 18 ins apart in the clear, the plates being allowed to sag a little between the rafters, so as to form shallow gutters. In such cases it is well to bevel off the tops of the rafters slightly, as in this fig.

A serious objection to iron as a roof covering, is its rapid condensation of atmospheric moisture; which falls from the iron in drops like rain, and may do injury to ceilings, floors, or articles in the apartments immediately beneath the roof. Painting does not appreciably diminish this; it may, however, be obviated by plastering.

Corrugated sheet iron. The size of sheets generally used for corrugating, is 30 inches wide by 96 inches long. Corrugation reduces the width to 27½ inches. When the corrugated sheets are laid upon the roof, the overlapping of about 2½ inches along the sides, and of 4 inches along their ends diminishes the area of roof covered by a sheet, to about seven-eighths of that of the entire corrugated sheet itself; or, the weight per square foot of roof covered, will be about one-seventh greater than that per square foot of the corrugated sheet, or, the weight of corrugated iron per square foot of roof covered is about one-fifth greater than that of the flat sheets from which it is made.

About 6 inches are usually allowed for the extension over the eaves.

The weights per square foot corresponding to the different numbers of the Birmingham wire gauge, vary somewhat with the different makers. The two styles of corrugation given in the table below 5 x 1¼ and 2½ x ⅝, are those most frequently used.

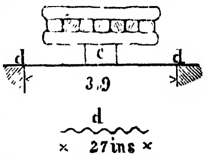
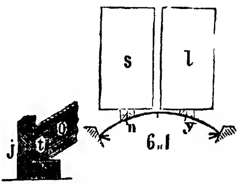
Strength of Corrugated Iron. Experiments by the author.



First. A sheet *d d*, of No. 16 iron, (about $\frac{1}{17}$ inch thick,) 27 ins wide, by 4 ft long, with five complete corrugations of 5 ins by 1 inch, was laid on supports 3 ft 9 ins apart A block of wood *c*, 9 ins wide, by 7 ins thick, and 30 ins long, was placed across the center, and gradually loaded with castings weighing 1600 lbs.

This caused a deflection at the center of precisely ½ an inch. On the removal of the load after an hour, no permanent set was appreciable. The severity of the test was purposely increased by applying the several castings very roughly, jolting the whole as much as possible.* The suspended area of the sheet was 8 44 sq ft; and since the actual *center* load of 1600 lbs is about equivalent to 3000 lbs *equally distributed*, it amounts to $\frac{3000}{8\ 44}$=355 lbs per sq ft distributed. But 3000 lbs distributed would produce a deflection of but about full ¼ of an inch. Again, 355 lbs per sq ft is about 4 times the weight of the greatest crowd that could well congregate upon a floor Consequently this iron, at 3' 9" span, is safe in practice for any ordinary crowd. Moreover, such a crowd would produce a center deflection of only the ¼th part of ¼ of an inch; or $\frac{1}{16}$ of an inch; or $\frac{1}{720}$ of the clear span; which is but two-thirds of Tredgold's limit of $\frac{1}{480}$ of the span.

In one experiment the ends of the sheets rested upon supports dressed so as to present undulations corresponding tolerably closely with the shape of the corrugations; but in the other the supports were flat, and each end of the sheet rested only upon the lower points of the corrugations. No appreciable difference was observed in the results.



Second. An arch of No. 18 ($\frac{1}{20}$ inch) iron. corrugated like the foregoing, but the depth of corrugation increased to 1¼ ins by the process of arching the sheet; clear span 6 ft 1 inch; rise 10 ins; breadth 27 ins, (of which however, only 25 ins bore against the abutments.)

Each foot *o* of the arch abutted upon a casting *j*, the inner portion *t* of which was undulated on top, to correspond with the corrugations of the arch, which rested upon it. At *y*, (one-fourth of the span,) two wooden blocks were placed, occupying a width of 9 inches, and extending across the arch; on them was piled a load, *l*, of castings, to the extent of 4480 lbs, or 2 tons. Under this load the arch descended about half an inch at *y*, becoming flatter on that side and slightly more curved upward along the unloaded side *n*. Two similar blocks were then placed at *n*, and two tons of load, *s*, were piled upon them, in addition to the 2 tons at *l*; making a total of 8960 lbs, or 4 tons. This brought the arch more nearly back to its original shape; but still slightly straightened at both *n* and *y*, and a little more curved in the center. The load was then increased to 10000 lbs, and left standing for several days. Two iron ties, each ½ by 1¾, which were used for preventing the abutment castings *j* from spreading, were found to have stretched nearly ¼ of an inch. Additional ones were inserted, and the load increased to a total of 6 tons, or 13440 lbs, parts of it on *s* and *l*, and part in the shape of long broad bars of iron at the center of the arch, below the loads *s* and *l*, and between *n* and *y*. So far as could be judged by eye, the shape of the arch was now almost perfect. *The loads s and l did not touch each other.* After standing more than a week, the load was accidentally overturned, crippling the arch The load was equal to about 1000 lbs per sq ft of the arch. Such arches have since come into common use instead of brick, **for fireproof floors.**

Curved roofs of 25 to 30 ft span. rising about ¼ span, may be made of ordinary corrugated iron of Nos 16 to 18, riveted as usual; and having no accessories except tie-rods a few feet apart; continuous angle-iron skewbacks; and thin vertical rods to prevent the ties from sagging.

* Without letting the deflection exceed ½ inch; which was prevented by a stop under the sheet.

Welded wrought-iron pipes, for steam, gas, and water. Usually in lengths of about 18 feet. Standard sizes.

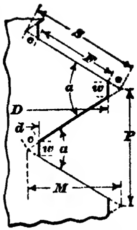
Screw Threads, Bolts, Nuts, and Washers.



Screw threads. a = angle between two sides of a thread; P = pitch; w = width of flat top or bottom of each thread; all measured in a plane containing the axis of the screw; N = number of threads per inch, = 1/P. In the **Sellers or Franklin Institute Standard,** proposed by Mr. William Sellers and adopted by the Institute in 1864, $a = 60°$; S = P; w = P/8; F = 0.75 P; M = P cos a/2 = 0.8660 P; D (diameter) = d + 2 × 0.866 × 0.75 P = d + 1.299 P. Under the name of **United States Standard,** the U. S. Navy Department in 1868 adopted the Sellers system, except for finished heads and nuts, which it made the same as for rough heads and nuts.

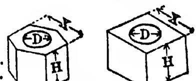
Dimensions of Heads and Nuts.

	Rough.	Finished.
X	1½ D + ⅛ inch.	1½ D + 1-16 inch.
H (in *head*)	½ X.	D − 1-16 inch.
H (in *nut*)	D.	" "



Figs. 2

In the **Whitworth** (English) **standard** thread, the angle a, Fig 1, is 55°. The tops and bottoms of the threads are rounded, instead of flat as in the American standards. The number (N) of threads per inch is the same as above for diams of bolt up to three ins, except for D = ½ inch; where N = 12.

In the **International metric screw thread,** adopted at Zurich, October, 1898, the Sellers thread profile is used. The dimensions are as follows, all in millimeters:

<table>
<tr><td>Diam.</td><td>6</td><td>7</td><td>8</td><td>9</td><td>10</td><td>11</td><td>12</td><td>14</td><td>16</td><td>18</td><td>20</td><td>22</td><td>24</td><td>27</td><td>30</td><td>33</td><td>36</td><td>39</td><td>42</td><td>45</td><td>48</td><td>52</td><td>56</td><td>60</td><td>64</td><td>68</td><td>72</td><td>76</td><td>80</td></tr>
<tr><td>Pitch</td><td colspan="2">1.0</td><td colspan="2">1.25</td><td colspan="2">1.5</td><td>1.75</td><td colspan="2">2 0</td><td colspan="3">2.5</td><td colspan="2">3.0</td><td colspan="2">3.5</td><td colspan="2">4.0</td><td colspan="2">4.5</td><td colspan="2">5.0</td><td colspan="2">5.5</td><td colspan="2">6.0</td><td colspan="2">6.5</td><td>7.0</td></tr>
</table>

Intermediate diameters are to be of an integral number of millimeters, and of the same pitch as the next smaller diameter in the table. Thus, for diam 65 or 69 mm; pitch = 6.0 mm.

Plate-iron washers. Standard sizes. Diameters of washers and bolt-holes in inches. Approximate thickness by Birmingham wire gauge. Approximate number in one lb.

A *square* head and nut together, weigh about as much as a length of the bolt equal to 7 or 8 times D. *Hexagon*, 6 or 7.

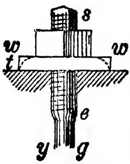

Fig 3

With the above dimensions a bolt will generally fail by breaking off between the head and the nut, where the diameter is decreased by cutting the thread, rather than by stripping off its threads. **The diam D of the thread** must of course be greater than that required to bear safely the proposed tensile strain, by an amount equal to *twice* the depth of the thread. The waste of iron, which would result from making the *entire bolt* of this greater diam, is frequently avoided by making the bolt from a bar of only sufficient dimensions to bear the strain safely, **and upsetting its ends** as in Fig 3, thus increasing their diam sufficiently to allow for the cutting of the threads.

In carpentry, as well as in ties for masonry, *washers, w w*, of either cast or wrought iron, are placed between the timber, or stone, and the head and nut in order to distribute the pressure over a greater surface, and thus prevent crushing; especially in timber.

When much strained against wood, the side of a square wrought-iron washer, or the diam *w w* of a circular one, should not be less than 4 diams of the *screw*, as in the fig; and its thickness, *t w*, ½ diam *at least*.

Two such square washers will together weigh as much as 18 diams in length of a round rod of the same diam as the screw. Two round washers will weigh together as much as 14 diams of rod of same diam as screw. In either case, a square head and nut will weigh as much as 6 diameters. Cast iron washers, being more apt to split under heavy strains, may be made about twice as thick as wrought ones. When the strain is very great, the diam of the washer may be 5 or 6 times that of the screw, and its thickness equal to diam; but 4 diams will suffice for most practical purposes, or even 2 5 when there is but little strain, and the thickness may then be but .1 or .2 diam of bolt.

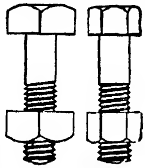

Fig. 4. Fig. 5.

Table of machine and car bolts, with square and hexagon heads and nuts, Figs 4 and 5; made by Hoopes & Townsend, 1330 Buttonwood St, Phila. All their **bolts are cut with U. S. Standard threads**, as per first table on p 1165, unless otherwise ordered. Discounts, see price list.

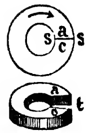
Expansion bolts, for fastening plates, timbers, etc., to walls of brick or masonry. The wedge-shaped nut, traveling up the bolt, as the latter is turned, presses the wings against the sides of the hole, which, in practice, is drilled just large enough to admit the nut and wings, so as to prevent the former from turning with the bolt. If the hole is made larger, as shown, the nut must be held by a small wedge.



Lock-nut washers. When bolts are subjected to much rough jolting, as at rail-joints, &c, the *nuts are liable to wear loose, and unscrew themselves.* On railroads this is a source of great annoyance, and innumerable devices for preventing it have been tried. The **Verona** lock-nut washer* is a simple circular washer made of steel; with a slit *s s* cut through it, leaving sharp edges. On one side, *a*, of the slit, the metal is pressed upward about ⅛ inch; and that on the other side, *c*, downward, the same distance; so that a perspective view would be somewhat as at *t*. Now, when the nut is screwed down over the washer, in the direction of the arrow, the slit offers no obstruction; but if the nut afterward tends to unscrew itself, the sharp upper edge of the slit, along *a*, presents friction against the bottom of the nut, which tends to hold it in place. Besides, the washer, by its elasticity, tends to resume its original shape, and thus presses the threads of the nut against those of the bolt; and the additional friction thus produced also aids in holding the nut.

Another lock-nut washer consists of a long strip of steel, with *two* holes, each of which has its edges formed like those of a Verona washer, and through *each* of which passes one of the bolts of the rail-joint.

Another device is to cut, at the end of the screw, a few threads of a screw of less diameter than the main one, and in the opposite direction. The nut is then screwed upon the larger diameter; and after it the lock-nut is screwed in the other direction upon the smaller diam, until it comes into contact with the main nut. In the **Smith** lock-nut bolt, this second nut is only about ⅛ inch thick; and after being driven home, one of its corners is bent over the edge of the main nut.

The **Atwood** lock-nuts take advantage of elasticity in the nut itself, which is obtained either by slitting the nut, or by reducing its thickness near the bolt hole.

It is claimed that if the threads of an ordinary bolt and nut are carefully cut, so as to be in contact with each other throughout, no lock-nut contrivance is necessary, because the friction between the two threads is distributed over a larger surface, and *abrasion* does not take place so readily as if the threads touched each other at only a few points. The nuts are therefore less apt to wear loose under repeated jarring.

Owing to the difficulty of obtaining such perfect fitting bolts and nuts, due to the wear of the cutting tools used in their manufacture, bolts and nuts have been made in which the thread on the bolt differs slightly in shape from that in the nut. They also furnish nuts in which the thread, instead of being of uniform shape throughout, gradually becomes *deeper* and *thicker*, by having its side angle made more acute, and its top truncated. These nuts are used with bolts having the usual uniform thread. The bolt enters the nut upon the side where the thread is of the same shape as its own; but its thread encounters, and is forced into, the gradually narrowing and deepening path between the threads of the nut. In both devices, the enforced conformity between the two threads is relied upon to give the desired completeness of contact between them. The greater force required in screwing on the nut also increases the *friction* between the threads.

BUCKLED PLATES.

Buckled plates are usually of steel, ¼ to ½ in thick and 3 to 4 ft sq; sometimes in long plates having several buckles each. Buckle 2 to 8 ins. Flat rim or fillet, 2 to 4 ins. They are used for the floors of buildings and of highway bridges.

Total permissible load, lbs. on a single square buckled plate of any size and thickness.† Load = $4\,k\,t\,h$; where k = permissible unit stress in metal, lbs per sq in, say 6000; t = thickness of metal, ins, and h = depth of buckle, ins.

Buckled plates are stronger, and require less concrete, etc, for filling, when laid with convex side down. They weigh but little more than flat plates, or about 10 lbs per sq ft per ¼ in of thickness.

---

* Invented by Mr. Thomas Shaw, M. E., of Philadelphia.

† "Steel in Construction," by Pencoyd Iron Works, Philadelphia, 1900, p 147.

WEIGHT AND STRENGTH OF IRON BOLTS. (Original.)

Diameters, weights, and approximate breaking strains, **for round bolts;** breaking strain per square inch assumed as follows: Up to 1 inch square, or 1 inch diam, 20 tons, or 44800 lbs; from 1 to 2 ins sq or diam, 19 tons; 2 to 3 ins, 18 tons; 3 to 4 ins, 17 tons; 4 to 5 ins, 16 tons; 5 to 6 ins, 15 tons.

A long upset rod is no stronger than one not upset, against *slowly applied* loads or strains. Both will then break at about midlength, under equal pulls. In such cases use columns 5 and 6.

Square bars. Strength or wt = 1.273 × strength or weight of round bar.

Copper bars. {Strength = 0.8 × strength of similar iron bar. Weight = 1.14 × weight " " " "

The Birmingham **wire gauge** is the one in most general use for **iron**. The new British w g went into effect March 1st 1884. In the "American" w g of Darling, Brown & Sharpe, Providence R. I., each diam or thick is = the next smaller one × 1.122932. We take the wt of wrot iron per cub ft at 485 lbs in the first two; and at 486 in the last. For the **wt of steel**, mult that of iron by 1.01. For **lead**, mult iron by 1.46. For **zinc**, mult iron by .9. For **brass** (approx), mult iron by 1.06. For **copper**, mult iron by 1.134.

American gauge for sheet and plate iron and steel (**1893**). We omit *the columns of weight in kilograms per square foot and in pounds per square meter, and simplify the headings of the remaining columns.*

An Act establishing a standard gauge for sheet and plate iron and steel.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That for the purpose of securing uniformity the following is established as the only standard gauge for sheet and plate iron and steel in the United States of America, namely.

No.	Approximate thickness: Inches.	Approximate thickness: Millimeters.	Weight: Per sq. foot, in avoirdupois ounces.	Weight: Per sq. foot, in avoirdupois pounds.	Weight: Per sq meter, in kilograms

And on and after July first, eighteen hundred and ninety-three, the same and no other shall be used in determining duties and taxes levied by the United States of America on sheet and plate iron and steel. But this act shall not be construed to increase duties upon any articles which may be imported.

SEC. 2. That the Secretary of the Treasury is authorized and required to prepare suitable standards in accordance herewith.

SEC. 3. That in the practical use and application of the standard gauge hereby established a variation of two and one-half per cent. either way may be allowed.

Approved March 3, 1893.

CIRCULAR MEASURE.

Used in comparing cross sections of wires, etc.

A circular unit is the area of a circle whose diameter is one linear unit. Thus, a circular inch is the area (= 0.7854 square inch) of a circle whose diameter is one inch.

The following table is adapted, by permission, from Mr. Carl Hering's valuable Tables of Equivalents of Units of Measurement, New York, 1888. Inasmuch as we take 1 meter = 39.37 inches, instead of 39.37079 inches, our values differ slightly from his.

			Logarithm.

EDISON STANDARD WIRE GAUGE.

Adopted by the Associated Edison Illuminating Companies.

In this table the gauge number is approximately equal to

$$\frac{1}{1000} \times \text{area of cross section in circular mils*}$$
$$= \frac{1}{1000} \times \text{square of diameter in mils*}$$

No.	Diameter, in mils.	No.	Diameter, in mils.	No.	Diameter, in mils.

* 1 mil = $\frac{1}{1000}$ inch.

No trade Stupidity is more thoroughly senseless than the adherence to the various Birmingham, Lancashire, &c, gauges; instead of at once denoting the thickness and diameter of sheets, wire, &c, by the parts of an inch; as has long been suggested. Thus, No. $\frac{1}{8}$, or No. $\frac{1}{20}$ wire, or sheet-metal of any kind, should be understood to mean $\frac{1}{8}$ or $\frac{1}{20}$ of an inch diam, or thickness. To avoid mistakes, which are very apt to occur from the number of gauges in use; and from the absurd practice of applying the same No. to different thicknesses of different metals, in different towns, it is best to ignore them all; and in giving orders, to define the diameter of wire, and the thickness of sheet-metal, by parts of an inch. Or the weight per hundred ft for wire; or per sq ft for sheets, may be employed. We *believe* that the *foregoing* Birmingham gauge applies to zinc, copper, brass, and lead; although it is generally stated to be for iron and steel only. Another Birmingham gauge is used for sheet-brass, gold, silver, and some other metals; but we have never seen it stated what those others are. There are different gauges even for wire to be used for different *purposes;* and various firms have gauges of their own; not even according among themselves.

As Mr. Stubs makes various English gauges, the term "**Stubs gauge**" *by itself* means nothing. Generally, however, in our machine shops, it applies to the Birmingham gauge of the preceding table.

Birmingham gauge for sheet Brass, Silver, Gold, and all metals except iron and steel?

No.	Thickn's.	No.	Thickn's.	No.	Thickn's.	No	Thickn's	No.	Thickn's.	No.	Thickn's.

4	.010	10	.024	16	.051	22	.074	28	.120	34	.148
5	.012	11	.029	17	.057	23	.077	29	.124	35	.158
6	.013	12	.034	18	.061	24	.082	30	.126	36	.167

The mills rolling sheet iron in the United States generally use the following, which varies slightly from the Birmingham gauge:

No.	lbs per sq ft	No.	lbs per sq ft	No.	lbs per sq ft	No.	lbs per sq ft
1	12.50	8	6.86	15	2.81	22	1.25
2	12.00	9	6.24	16	2.50	23	1.12
3	11.00	10	5.62	17	2.18	24	1.00
4	10.00	11	5.00	18	1.86	25	.90
5	8.75	12	4.38	19	1.70	26	.80
6	8.12	13	3.75	20	1.54	27	.72
7	7.50	14	3.12	21	1.40	28	.64

When wire, sheet-metal, &c., are ordered by gauge number, and it is not specified what gauge is intended; dealers in the United States fill the order as follows:

Brass, bronze or German Silver in sheets, German Silver wire, brazed brass, bronze, zinc or copper tubing, by Brown & Sharpe's (or "American") gauge.

Copper in sheets; brass and copper wire; seamless brass, bronze or copper tubing; and small brass rods; by Stubs' (or Birmingham) gauge.

Unannealed or hard **brass wire** has about $\frac{3}{4}$ths the strengths of the table p. 1173, and about $\frac{1}{6}$ more weight. If annealed, only full half the strength.

Hard copper wire may be taken at $\frac{2}{3}$ of the tabular strengths, and full $\frac{1}{4}$ more weight.

Table of Charcoal Iron Wire made by Trenton Iron Co., Trenton, N. J. The numbers in the first column are those of the **Trenton Iron Co's gauge.** The corresponding diameters in the second column will be seen to be somewhat less than those of the Birmingham gauge.

9	.145	17.950	1507	24	.0225	745.710	......	39	.0075	6724.291
10	.130	22.833	1233	25	.020	943.396	......	40	.007	7698.258

The wire in this table is supposed to be hard, bright, or unannealed. The figures in the column of tensile strength are based upon tests made with good charcoal iron wire from Trenton blooms.

The tensile strength of wire made of	is about		
Good refined iron..............	15 per cent. less		than that of bright charcoal wire, given in the above table.
Swedish charcoal iron................	10 " "		
Mild Bessemer steel....................	10 " more		
Ordinary crucible steel..................................	25 " "		
Special crucible steel....................................	30 to 120 " "		

Annealing renders wire more pliable and ductile, but less elastic; and reduces the tensile strength by from 20 to 25 per cent.

To find approximately the number of straight wires that can be got into a cable of given diameter.

Divide the diameter of the cable in inches, by the diameter of a wire in inches. Square the quotient. Multiply said square by the decimal .77. The result will be correct within about 4 or 5 per cent at most, in a *cylindrical* cable.

The solidity, or metal area of all the wires in a cable, will be to the area of the cable itself, about as 1 to 1.3. In other words, the area of the voids is nearly ¼ that of the cable; while that of the wires is fully ¾ that of the cable. All approximate.

No trade Stupidity is more thoroughly senseless than the adherence to the various Birmingham, Lancashire, &c, gauges; instead of at once denoting the thickness and diameter of sheets, wire, &c, by the parts of an inch; as has long been suggested. Thus, No. $\frac{1}{8}$, or No. $\frac{1}{20}$ wire, or sheet-metal of any kind, should be understood to mean $\frac{1}{8}$ or $\frac{1}{20}$ of an inch diam, or thickness. To avoid mistakes, which are very apt to occur from the number of gauges in use; and from the absurd practice of applying the same No. to different thicknesses of different metals, in different towns, it is best to ignore them all; and in giving orders, to define the diameter of wire, and the thickness of sheet-metal, by parts of an inch. Or the weight per hundred ft for wire; or per sq ft for sheets, may be employed. We *believe* that the *foregoing* Birmingham gauge applies to zinc, copper, brass, and lead; although it is generally stated to be for iron and steel only. Another Birmingham gauge is used for sheet-brass, gold, silver, and some other metals; but we have never seen it stated what those others are. There are different gauges even for wire to be used for different *purposes;* and various firms have gauges of their own; not even according among themselves.

As Mr. Stubs makes various English gauges, the term "**Stubs gauge**" *by itself* means nothing. Generally, however, in our machine shops, it applies to the Birmingham gauge of the preceding table.

Birmingham gauge for sheet Brass, Silver, Gold, and all metals except iron and steel?

The mills rolling sheet iron in the United States generally use the following, which varies slightly from the Birmingham gauge:

No.	lbs per sq ft	No.	lbs per sq ft	No.	lbs per sq ft	No.	lbs per sq ft
1	12.50	8	6.86	15	2.81	22	1.25
2	12.00	9	6.24	16	2.50	23	1.12
3	11.00	10	5.62	17	2.18	24	1.00
4	10.00	11	5.00	18	1.86	25	.90
5	8.75	12	4.38	19	1.70	26	.80
6	8.12	13	3.75	20	1.54	27	.72
7	7.50	14	3.12	21	1.40	28	.64

When wire, sheet-metal, &c., are ordered by gauge number, and it is not specified what gauge is intended; dealers in the United States fill the order as follows:

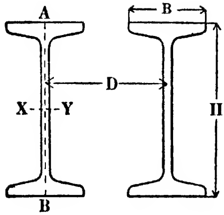
Brass, bronze or German Silver in sheets, German Silver wire, brazed brass, bronze, zinc or copper tubing, by Brown & Sharpe's (or "American") gauge.

Copper in sheets; brass and copper wire; seamless brass, bronze or copper tubing; and small brass rods; by Stubs' (or Birmingham) gauge.

Unannealed or hard **brass wire** has about $\frac{3}{4}$ths the strengths of the table p. 1173, and about $\frac{1}{9}$ more weight. If annealed, only full half the strength.

Hard copper wire may be taken at $\frac{2}{3}$ of the tabular strengths, and full $\frac{1}{7}$ more weight.

I-BEAMS.



The table gives the maximum and the minimum weight of each section. The minimum weights are standard. Others are special.

Caution.—With very short spans, the loads found by means of columns C_s and C_m, although safe against *bending*, may be so great as to endanger a *crushing* of the ends of the beam, or of the walls, etc., under them, unless the beam has, at its ends, a greater length of bearing than would otherwise be needed.

No trade Stupidity is more thoroughly senseless than the adherence to the various Birmingham, Lancashire, &c, gauges; instead of at once denoting the thickness and diameter of sheets, wire, &c, by the parts of an inch; as has long been suggested. Thus, No. $\frac{1}{8}$, or No. $\frac{1}{20}$ wire, or sheet-metal of any kind, should be understood to mean $\frac{1}{8}$ or $\frac{1}{20}$ of an inch diam, or thickness. To avoid mistakes, which are very apt to occur from the number of gauges in use; and from the absurd practice of applying the same No. to different thicknesses of different metals, in different towns, it is best to ignore them all; and in giving orders, to define the diameter of wire, and the thickness of sheet-metal, by parts of an inch. Or the weight per hundred ft for wire; or per sq ft for sheets, may be employed. We *believe* that the *foregoing* Birmingham gauge applies to zinc, copper, brass, and lead; although it is generally stated to be for iron and steel only. Another Birmingham gauge is used for sheet-brass, gold, silver, and some other metals; but we have never seen it stated what those others are. There are different gauges even for wire to be used for different *purposes;* and various firms have gauges of their own; not even according among themselves.

As Mr. Stubs makes various English gauges, the term "**Stubs gauge**" *by itself* means nothing. Generally, however, in our machine shops, it applies to the Birmingham gauge of the preceding table.

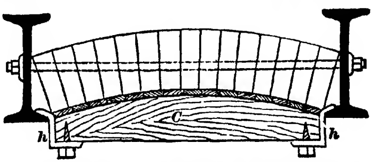
The weight of a 4-inch arch, with its concrete filling and wooden flooring, but exclusive of the beams, is about 70 lbs. per square foot of floor.

A dense crowd of persons will hardly weigh more than 80 lbs. per square foot.



Each center, *C*, has fastened to it at each end a bent iron strap, *h*, forming a hook by which the center is suspended from the lower flanges of the beams.

CARNEGIE ANGLES

d = distance between center of gravity and back of flange W
s = " " " " " " " " H
I, i = moment of inertia; **I**, about XY; **i**, about A B
X, x = least "section modulus"; **X**, " " **x**, " " $= \frac{12\ M}{S}$†
R, R' = radius of gyration; **R**, " " **R'**, " "
r = least radius of gyration, about neutral axis forming acute angle a with each flange. In angles with equal legs, $a = 45°$

C = coefficient for uniformly distributed safe load: C_s, for static loads; fibre stress = 16,000 lbs. C_m, for moving loads; fibre stress = 12,000 lbs. } For T shapes only.

CARNEGIE ANGLES

d = distance between center of gravity and back of flange W
s = " " " " " " " H
I, i = moment of inertia; **I,** about XY; **i,** about A B
X, x = least "section modulus"; **X,** " " **x,** " " = $\frac{12\ M}{S}$ †
R, R′ = radius of gyration; **R,** " " **R′,** " "
r = least radius of gyration, about neutral axis forming acute angle *a* with each flange. In angles with equal legs, $a = 45°$
C = coefficient for uniformly distributed safe load: C_s, for static loads; fibre stress = 16,000 lbs.; C_m, for moving loads; fibre stress = 12,000 lbs. — For T shapes only.

CARNEGIE STEEL Z-BAR COLUMNS.

Table of Safe Loads as given by Carnegie Steel Co., for columns with square ends. Safety factor = 4. The loads given are based upon the following allowed stresses in pounds per square inch:

For lengths of 90 radii or less, 12,000.

" " over 90 radii, $17,100 - 57 \frac{l}{r}$.

Each Z-bar column is made up of four Z-bars and one web-plate (all of uniform thickness) bolted or riveted together, as shown in the figure on page 1183.

6-inch Steel Z-bar Columns.

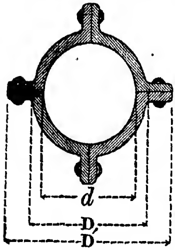
For loads greater than those given in the tables, the Z-bar columns may be re-enforced by additional plates, riveted to the flanges. The addition of such plates does not in any case diminish the least radius of gyration. Hence the same load *per square inch of cross-section* may be used.

Table of rolled-iron segment-columns of the Phœnix Iron Co, 410 Walnut St, Philada.



The **dimensions** given are subject to slight variations which are unavoidable in rolling iron shapes. The **weights** of columns given are those of the 4, 6, or 8 segments, of which they are composed The *shanks* of the rivets used in joining them together, of course, merely make up the quantity of metal punched or drilled out, in making the holes; but the rivet-*heads* add from 2 to 5 per cent to the weights given. The **rivets are spaced** 3, 4, or 6 ins apart from cen to cen.

Any desired thickness between the minimum and maximum for any given size, can be furnished. We give the dimensions, weights, &c, corresponding to the principal thicknesses. G columns have 8 segments, E, 6 segments. All others, 4 segments.

THE GRAY COLUMN.

The Gray Column, designed and patented by Mr. J. H. Gray, consists in its original form, of angles, connected at intervals D (generally of 2 ft 6 ins) by transverse bent tie-plates T, usually 9 × 3/8 ins. This construction renders the parts of the column easily accessible, for painting, etc., but under transverse or buckling stresses the column must act somewhat like a rectangular frame without diagonals. To remedy this, a later form, the "twelve-angle" column, Fig 5, has been designed, having, in the square column, Figs 1 and 2, instead of the bent tie-plates T, four additional angles, running longitudinally like the others, and placed centrally, as shown. These angles supply the column with two webs, intersecting at right angles.

Figs 1 and 2 show the square column, used in the interior of buildings. It is used chiefly in the 14, 15, and 16 inch sizes. Fig 2 shows plates riveted to the outer flanges, as is done in some of the heaviest columns. Figs 3 and 4 show the wall and corner columns respectively. Fig 5 shows the "twelve-angle" column, and Fig 6 one of many forms of fireproofing, with plaster laid on terra cotta blocks. The rivets are usually 3/4 inch in diameter.

The safe load, in pounds per sq inch, of the ordinary column, is stated as $17{,}100 - 57\frac{L}{r}$, where L = length of column and r = its least rad of gyration.

The cost of the Gray column, at shop, is from 1 to 1.5 cents per lb plus the cost of the angles.

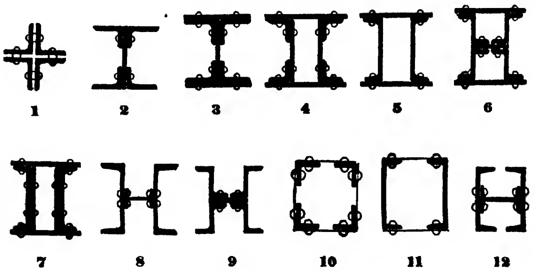
1. For economy of material, iron and steel columns are almost invariably **hollow.** Cast iron columns are usually round or rectangular; while structural steel columns are usually of some special or built-up shape, see Figs 1 to 12 and pp 1186, 1187.



Figs. 1 to 12.

2. Owing to displacement of the core, in casting, **cast iron columns** are apt to be much thinner on one side than on the other. They are liable to initial stresses, due to unequal contraction in cooling, and are objectionable also on account of the brittleness and relative unreliability of the material and its low tensile strength. When the metal, for very long columns, is poured at both ends of the mold, it may become so chilled that the two portions do not unite perfectly at the center. A weak place is thus left just where the max bending moment occurs. Entrained air produces blowholes and honeycomb; and impurities, collecting at the bottom of the mold, weaken the casting. See also ¶ 14.

See Columns in General, ¶¶ 9, 10, 13, and 35 to 43, pp 495, etc., 498 *c*. etc.

3. Avoid designs which, like those shown at *g* and at *a a*, Fig 13, bring part of the wall of the column out from the line of pres, inducing **bending moments** in the metal.

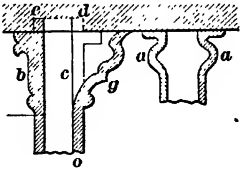


Fig. 13.

4. Use preferably a simpler form, as at *b*, or a straight col, *o c d*, to which any such ornaments, as at *g*, may be attached.

5. Figs 1 to 12 show **common forms of columns** built up of steel angles, plates, channels, and Z-bars. **"Closed" sections.** Figs 4 to 7, cannot be repainted internally. They are therefore suitable only for dry situations where temp changes are slight. In Figs 8, 10, 11, 12, the flanges should be placed far enough apart to permit machine-riveting.

6. Figs 14 to 17, from "Cambria Steel," show details of **connections** between one column and another and between columns and beams, as markt. Figs 18 to 20, from "Cambria Steel," show arrangement for **bases** of columns, as markt.

7. It is customary to provide that K, = L/r, shall not exceed about 125; but, in light structures, *K* sometimes greatly exceeds this limit. Thus, in eleven transmission towers, *K* ranged from 111 to 300. Where it reached 300, the member consisted of 1 angle, 2 × 2 × ⅛ inch, *L* = 120 ins ; *r* = 0.4 inch. (R. D. Coombs, Am Soc Civ Engrs, Trans, Vol 61, Dec 1908, p 202.)

8. In columns composed of two channels, latticed, Fig 11, the channels are usually placed so far apart that the tendency of the column will be to deflect in the plane of the webs, i. e., so that the least radius of gyration of the column is the greatest radius of gyration of the single channel. For proper distances between channels, to secure this result, see pp 1175 and 1177.

9. Angle sections being unsymmetrical, the load is usually more or less eccentric. Hence the allowable stress, for angle columns, should be less than that for symmetrical sections.

10. Rivets are usually spaced ≯ 3 inches, center to center, near the ends of columns, for a distance equal to twice the width of the column. Distance between centers of rivets, in line of stress, ≯ 16 times least thickness of metal of the parts joined. Distance between rivets, perp to line of stress, ≯ 32 times thickness of metal.

11. Lattice bars, batten plates and connections, weigh, together, 30 % or more of the weights of heavy columns, and 50 or 60 % of the weights of the lightest columns.

12. In building construction, **columns may be considered as square-ended.** Usual **factor of safety** = 4. See ¶¶ 14 and 18.

13. Columns of angles or I-beams are usually of **soft steel:** those of plates and angles, channels, plates or Z-bars are usually calculated as for **medium steel.**

14. Cast iron columns do not permit as rigid connections, to other columns or to beams, as do rolled steel and riveted columns. They should not be used, in buildings, with a safety factor less than 8. See also ¶¶ 2, 12, 18.

15. In order to obviate the **weakening effect of the rivet holes** in riveted steel columns, the **solid H column,** rolled in the Grey universal mill, and shown in cross section in Fig 21, is employed.

Fig. 21.

16. Let loads and stresses be in pounds, dimensions in inches; let
P * = the total load (supposed to be axial) on the column;
a = the area of cross section of the column;
p * = P/a = the average unit load on the column;
s * = the maximum existing unit stress in any cross section;
s_e = the unit stress at the elastic limit;
s_s = the maximum unit stress in a short column;
r = the least radius of gyration of the cross section;
D = the least external diameter, or least external dimension, of the cross section;
L = the length of the column;
K = L/r = the length ratio, or slenderness, of col, in terms of r;
k = L/D = the length ratio, or slenderness, of col, in terms of D;
m = a coefficient in the Rankine formula;
c = a coefficient in the straight-line formula;
F = safety factor.

17. We then have

Rankine formula, (Columns in general, ¶¶ 21–27, pp 497–8):

$$p = P/a = \frac{s}{1 + m K^2}; \qquad s = p\,(1 + m\,K^2).$$

Straight-line formula, (Columns in general, ¶ 29, p 498).

$$p = P/a = s_s - c\,K.$$

18. Safety factors. F, proposed by Mr. James Christie (1), p 157, for structural steel columns :

For flat and fixed ends, $F = 3 + 0.010\,K$
For hinged and round ends, $F = 3 + 0.015\,K$.

See ¶¶ 12 and 14.

* Under any given conditions, P and p are the total load and the avge unit load, respectively, corresponding to the extreme fiber stress, s, existing under those same conditions. Thus, P, p and s may be those corresponding to ultimate or safe or any other loading.

19. Below are given **tables of values commonly used** in connection with various **formulas** for steel and iron columns under static axial loading. See Columns in General, pp 495 etc:

RANKINE FORMULA.

$$p = \frac{P}{a} = \frac{s}{1 + mK^2} = s \cdot \frac{1}{1 + m\left(\frac{L}{r}\right)^2};$$

$$K = L/r = \sqrt{\frac{\frac{s}{p} - 1}{m}}.$$

As in ¶ 16 :
p = mean unit load on col ; **m** = a coefficient ;
s = maximum unit stress in cross section ;
K = L/r = unsupported length ÷ least radius of gyration.

See diagram of values of $\frac{p}{s} = \frac{1}{1 + mK^2}$, Fig 22, p 1198.

Values of s and of 1/m for steel and iron columns.

For list of references, see p 1189.

TS = ultimate tensile strength; $\mathbf{S_e}$ = elastic limit; **YP** = yield point, all in thousands of pounds per square inch.

Cast Iron

For Buildings. Ultimate Loads.

	s_s	c
Wm. H. Burr, flat ends, (13);	30,500	160
J. B. Johnson, flat ends, "Materials" p 366;	34,000	88

For Buildings. Permissible Loads.

	s_s	c
New York building code, (11) Sec 138; Min diam, 5 ins; min thickness, ¾ in, K_{max} = 70	11,300	30
Boston building code, (7) p 416; K_{max} = 70. (Cast iron columns forbidden in buildings over 75 feet high)	11,000	30

20. Prof. J. B. Johnson (14) p 150, for ult loads by his **parabolic formula** (see Columns in General, ¶ 28, p 498):

$$p \text{ ult} = s_e - \frac{s_e^2 K^2}{q \pi^2 E} = s_e - c_p K^2,$$

gives q = 6.4 for hinged ends, q = 10 for flat ends, and

	$K \not>$	s_e	c_p
Wrought iron, pin ends, ...	170	34,000	0.67
Wrought iron, flat ends, ...	210	34,000	0.43
Mild steel, pin ends, ...	150	42,000	0.97
Mild steel, flat ends, ...	190	42,000	0.62

Here, as in ¶ 16, let

s_e = elastic limit of the material; c_p = a coefficient;

K = L/r = unsupported length ÷ least radius of gyration.

21. Where the **least external dimension, D,** (instead of the least radius of gyration, r,) is given, the following method (15) for finding the unit load, p, by the Rankine formula, may be found convenient: Let

s = max permissible fiber stress;

$p = P/a = s/(1 + m K^2)$ = permissible static unit load;

$$n = \frac{D^2}{r^2} = \frac{\text{(least external dimension)}^2}{\text{(least radius of gyration)}^2}; \quad K = \frac{L}{r}; \quad k = \frac{L}{D}.$$

Then

$K^2 = n k^2$; and $p = s/(1 + m n k^2)$; or $p/s = 1/(1 + m n k^2)$.

For values of m, see ¶ 19, pp 1194–1196.

For values of p/s, see ¶ 22, p 1198.

For values of n, = $(D/r)^2$, see Columns in General, pp 353 a, 353 b

22. Diagram. Fig 22, **showing values of** $p/s = 1/(1 + mnk^2)$
(*a*) for medium and nickel steel and wrought iron;
(*b*) for cast iron.

In the scale of abscissas, find the ordinate corresponding to the given value of $k = L/D$. Find the intersection of this ordinate with the curve corresponding to the value of n, $= (D/r)^2$, for the given section, taken from the table, pp 353 *a*, *b*. Opposite this intersection, on the axis of ordinates, will be found the required value of p/s. Then $p = s\,(p/s)$.

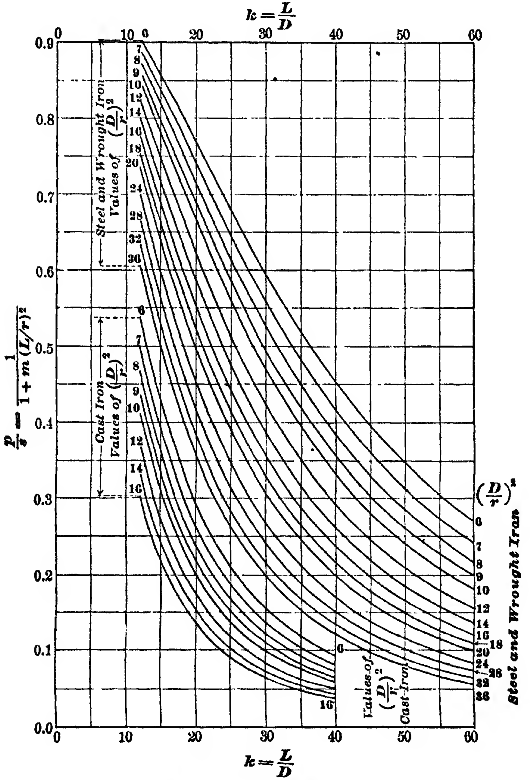

Fig. 22. Values of p/s.

23. Formulas and experiments. Figs 23 and 24 show a comparison between certain formulas for, and experiments upon, columns of **structural steel and cast iron,** as follows:

Formulas and Experiments.

Figs 23 and 24 (pp 1201 and 1203).

STRUCTURAL STEEL, Fig 23.

Formulas.

Rankine: $p = s/(1 + m K^2)$; **Straight-line:** $p = s_s - c K$.

p = mean unit load on column, **m, c** = coefficients;
s = maximum unit stress in cross section;
s_s = maximum unit stress in cross section for short blocks;
$K = L/r$ = length ÷ least radius of gyration; p and s in lbs per sq inch.

Ultimate.

24. The experiments on small solid cast iron cylinders, above recorded, and many others by Tetmajer (16), indicate that the Rankine formula is correct in form; but the experiments with actual hollow cylindrical columns show that such columns fail under loads lower than those given by the formula, especially in the case of short columns. In thin hollow cols, the eccentricity of loading, which is sure to occur, even in careful experiments, and much more so in actual building operations, concentrates most of the pressure upon one side, and causes that side to act without proper support from the rest of the section. The col is thus prevented from acting as a whole.

25. Tetmajer (16), p 77, finds that **riveted columns** of structural steel **behave the same as simple rolled shapes**, provided: —
(1) the pitch of the rivets does not exceed 70 × entire flange thickness;
(2) the rivets completely fill the rivet holes;
(3) the weakening of the section by rivet holes ≯ about 12 per cent.

26. Quebec bridge failure. The collapse of the southern portion of the great steel cantilever bridge over the St. Lawrence river, near Quebec, on August 29, 1907, during construction, appears to have been due to the failure of a main compression member, "*A* 9 *L*," in the anchor arm. This member, Fig 25, 57 feet long, was composed of four webs, each from 3½ to 3¾ inches thick (made up of four plates, about ⅞ inch thick, riveted together) and 4 ft 6 ins wide, provided with flange angles 6 × 8 ins and 3½ × 8 ins, and spaced as in Fig 25, and connected with each other by latticing of 4″ × 3″ × ⅝″ and 3½″ × 3″ × ⅜″ angles on top and bottom, the angles being replaced by ½ inch batten plates for several feet at each end. The radius of gyration of the four webs alone, including the longer legs of the flange angles, acting unitedly, about the axis *a b*, is 19.5 inches. This gives, for the entire section, acting unitedly, L/r = 684/19.5 = 35.1.

27. According to the stress sheet, this member was **designed to sustain**, in service: —

Dead load, ...	11,249,000	pounds	
Live load, ...	4,019,000	"	
Dead and live load, ...	15,268,000	"	= 19,710 pounds per sq inch.
Wind	± 7,370,000	"	

28. For compression members where L/r is (as in this case) < 50, the **specification permitted** a load, in pounds per square inch, of

$$12{,}000\left(1 + \frac{\text{minimum stress}}{\text{maximum stress}}\right)^* \text{ or, in this member, of}$$

$$12{,}000 \times 1.7317^* = 20{,}780 \text{ lbs per square inch.}$$

29. The member appears to have sustained, at the time of its failure, an average pressure of about 12,500,000 ÷ 780 = say 16,000 lbs per square inch.

---

* Min stress = dead load — min live load
= 11,249,000 — 45,000 = 11,204,000.
Max stress = dead load + max live load + min live load
= 11,249,000 + 4,019,000 + 45,000 = 15,313,000.

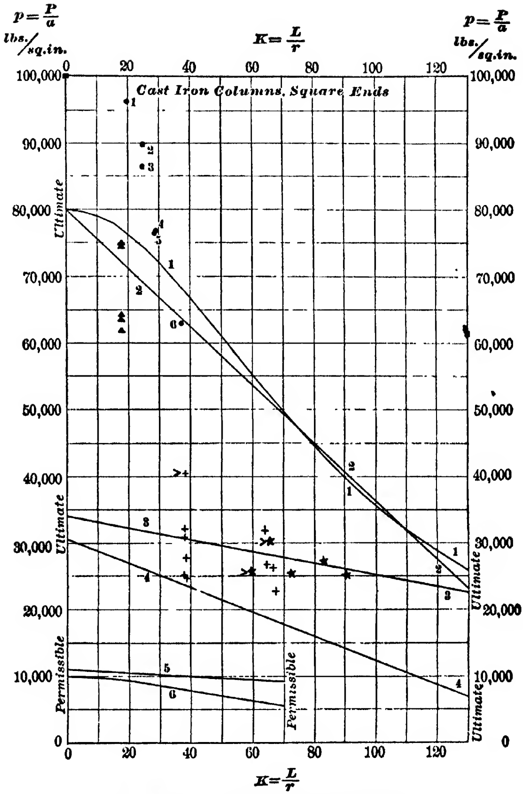

Fig. 24. Cast Iron Columns.

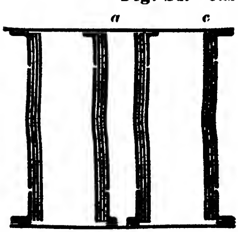

Fig. 25.
"A 9 L," Quebec bridge.

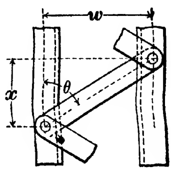

Fig. 26.
Lattice formulas.

30. Each of the four webs, including the longer leg of its flange angle, has, about its own neutral axis, cd, a radius of gyration of only about 1 inch, making its $L/r > 650$. For columns where L/r exceeds 50, the specification allows a load of only

$$(12{,}000 - 50\ L/r)\ \left(1 + \frac{\text{min stress}}{\text{max stress}}\right),^*$$

which, if applied to one of these webs, would permit only a *minus* load of some 35,000 lbs per square inch; but reliance was of course placed upon the angle latticing and upon the batten plates, to compel these four webs to act unitedly.

31. After the collapse of the structure, however, this member was found bent into the shape of a letter S, and the deflection occurred at right angles to the planes of the four webs, or in that direction in which it would have occurred if the bracing had been omitted. "The failure of lower chord $A\ 9\ L$ is an example of an insufficient lattice system." (Report of Quebec Bridge Commission.)

Stresses in Latticing.

32. "The unsatisfactory nature of the column formulas ..... is a matter of common knowledge among engineers, but **the column formulas may be considered to represent exact science in comparison with the lattice formulas.** Lattice formulas . ... fix, in a fashion, a value of the extreme fiber stress in the lattice bar, but only tests and experience can determine whether these give economical and safe results." (Report of Quebec Bridge Commission.)

33. The following **approximate method** (see communications from **Prof. Clyde T. Morris,** Ohio State University, Eng News, Nov 7, 1907, p 487, Feb 27, 1908, p 44) assumes (1) that the diagram of moments, in the columns, is a straight line, i e, that the increment of stress, per unit of length of column, is constant. This assumption makes the max stress, in the leaves, for a given max mom, less than it probably is; but, on the other hand, it is also assumed (2) that the stress, in the extreme fibers of the leaves, is uniformly distributed over the cross section of each leaf. This assumption (made because each portion of the leaf, between lattice connections, may deflect in either direction) makes the average stress greater than it is.

34. In a latticed (or "laced") column, composed of two leaves, Fig 26, let

s = max allowable unit comp stress in cross section of col
= max allowable unit comp stress in short blocks of the given material;
P = max allowable total load on column;
a = area of cross section of column;
p = P/a = max allowable avge unit comp stress, in cross section of col;
L = unsupported length of column;
r = least radius of gyration;
V = total stress transferred, by the lacing, from one leaf to the other
= half diff of stress betw the two leaves;
l = distance within which V is transferred;
v = V/l = increment of total stress, V, per unit of length of col;
w = dist betw rivet lines of lacing in the two leaves;
θ = angle betw lattice and axis of col;
x = $w\,.\cot\theta$ = longitudinal spread of one lattice bar;
n = number of lattice bars in each lattice panel;
vx/n = increment of stress, within x, in one lattice bar;
c = coeff in straight-line col formula $p = s - c\ L/r$;
= a small stress, of the same kind with s;
P_L = total longitudinal stress in one lattice bar.

* See foot-note *, p 1202.

35. Then

$V = (s - p)\ (a/2)$

$= \text{diff of unit stress} \times \text{area of one leaf}$ .... (1)

$v = V/l = (s - p)\ a\ /\ 2l$ .... (2)

$= \left(s - s + c\ \frac{L}{r}\right) a/2\,l = c\,L\,a\ /\ 2\,l\,r$ .... (3)

$v\,x/n = v\,w \cot\theta/n$ .... (4)

$$P_L = (v\,x/n) \sec\theta = \frac{v}{n} \cdot \frac{w}{\sin\theta}$$

$$= \frac{c\,L\,a}{2\,l\,r\,n} \cdot \frac{w}{\sin\theta} \quad \text{............ (5)}$$

36. In pin-end and round-end cols, the elastic curve is a simple one, and we have, for the dist, l, within which V is transferd, $l = L/2$; and $L\ /\ 2l = 1$.

In square-end and fixt-end cols, the curve reverses, with two points of contrary flexure; and we have: $l = L/4$, and $L\ /\ 2l = 2$.

Hence:

with round ends, $\mathbf{P_L} = \frac{c\,a}{r\,n} \cdot \frac{w}{\sin\theta}$ .... (6)

with square ends, $\mathbf{P_L} = \frac{2\,c\,a}{r\,n} \cdot \frac{w}{\sin\theta}$ .... (7)

37. The following **approximate method** (see **W. C. Armstrong,** Westn Soc of Engrs, Journal, June 1908, p 337) gives the total stress, P_L, in one lattice bar, **when the col is equally liable to fail in either direction.**

It is assumed that the tie plates carry 1/4, and the lacing 3/4, of the shear between the leaves. Let

d = depth of leaf;
I = mom of inertia of cross section;
$M = 2\,s\,I/d$ = resisting mom against bending in either direction; other symbols as in ¶ 34.

38. Then

$V = M\ /\ w = 2\,s\,I\ /\ d\,w$ .... (1)

$v = V\ /\ l = 2\,s\,I\ /\ d\,w\,l$ .... (2)

$v\,x\ /\ n = 2\,s\,I\,x\ /\ d\,w\,l\,n = 2\,s\,I \cot\theta\ /\ d\,l\,n$ .... (3)

$\mathbf{P_L} = \frac{3}{4} \cdot \frac{v\,x}{n} \cdot \sec\theta = \frac{1.5\,s\,I}{d\,l\,n \sin\theta}$ .... (4)

With round ends, $l = L/2$; and $\mathbf{P_L} = \frac{3\,s\,I}{d\,L\,n \sin\theta}$ .... (5)

With square ends, $l = L/4$; and $\mathbf{P_L} = \frac{6\,s\,I}{d\,L\,n \sin\theta}$ .... (6)

39. Supposing the lattice members themselves to be sufficiently strong, the integrity of the lattice system is still **limited by the possibility of rivet-slip,** the resistance to which, at any joint, is = No. of rivets × rivet section area × unit frictional resistance of rivets.

Prof. J. B. Johnson (Materials of Construction, pp 526–7) gives 12,000 lbs per sq in of rivet section as the **frictional resistance** for steel rivets; 10,000 lbs for iron rivets.

40. "**The size and strength of the pin** used have an appreciable effect on the results obtained, but the amount of this effect has not been determined." (Report of Quebec Bridge Commission.)

41. "**A compression member,** of usual design and dimensions cannot be expected to develop an ultimate strength much greater than about half that of **a tension member** made from the same material." *Ibid.*

PENCOYD FLOOR SECTIONS.

L = span, in feet.
C = coefficient.
W = distributed load, in lbs, per foot of floor width.

$$W = \frac{C}{L}.$$

Corrugated flooring, for bridges and buildings.
W = load producing fiber stress of 15,000 lbs per square inch.

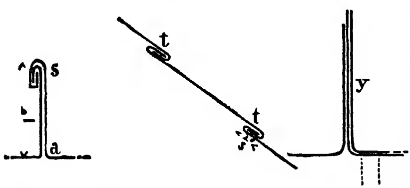
15-16	9.	43277	19.32	3	105.	398944	178.1

The links of ordinary iron chains are usually made as short as is consistent with easy play, in order that they may not become bent when wound around drums, sheaves, &c.; and that they may be more easily handled in slinging large blocks of stone, &c. U. S. Government experiments, 1878, prove that studs weaken the links.

When so made, their weight per foot run is quite approximately 3½ times that of a single bar of the round iron of which they are composed. Since each link consists of two thicknesses of bar, it might be supposed that a chain would possess about double the strength of a single bar; but the strength of the bar becomes reduced about 30 per cent, by being formed into links; so that the chain has but about 70 per cent of the strength of two bars. As a thick bar will not sustain as heavy a unit stress as a thinner one, so of course, stout chains are proportionally weaker than slighter ones. In the foregoing table, 20 tons *per square inch*, is assumed as the average breaking strain of a single straight bar of ordinary rolled iron, 1 inch in diameter or 1 inch square; 19 tons, from 1 to 2 inches; and 18 tons, from 2 to 3 inches. Deducting 30 per cent from each, we have as the breaking strain of the two bars composing each link, as follows: 14 tons *per square inch*, up to 1 inch diameter; 13.3 tons, from 1 to 2 inches; and 12.6 tons, from 2 to 3 inches diameter; and upon these assumptions the table is based. The weights are approximate; depending upon the exactness of diameter of the iron, and shape of link.

TIN AND ZINC.

The pure metal is called block tin. When perfectly pure, (which it rarely is, being purposely adulterated, frequently to a large proportion, with the cheaper metals lead or zinc,) its sp grav is 7.29; and its weight per cub ft is 455 lbs. It is sufficiently malleable to be beaten into tin foil, only $\frac{1}{1000}$ of an inch thick. Its tensile strength is but about 4600 lbs per sq inch; or about 7000 lbs when made into wire. It melts at the moderate temperature of 442° Fah. Pure block tin is **not used for common building purposes; but thin plates of sheet iron, covered with** it on both sides, constitute the *tinned plates*, or, as they are called, the *tin*, used for covering roofs, rain pipes, and many domestic utensils. For roofs it is laid on boards.



The sheets of tin are united as shown in this fig. First, several sheets are joined together in the shop, end for end, as at *tt*; by being first bent over, then hammered flat, and then soldered. These are then formed into a roll to be carried to the roof; a roll being long enough to reach from the peak to the eaves. Different rolls being spread up and down the roof, are then united along their sides by simply being bent as at *a* and *s*, by a tool for that purpose. The roofers call the bending at *s* a *double groove*, or *double lock;* and the more simple ones at *t*, a *single groove*, or lock.

To hold the tin securely to the sheeting boards, pieces of the tin 3 or 4 ins long, by 2 ins wide, called cleats, are nailed to the boards at about every 18 ins along the joints of the rolls that are to be united, and are bent over with the double groove *s*. This will be understood from *y*, where the middle piece is the cleat, before being bent over. The nails should be 4-penny slating nails, which have broader heads than common ones. As they are not exposed to the weather, they may be of plain iron.

Much use is made of what is called leaded tin, or ternes, for roofing. It is simply sheet-iron coated with lead, instead of the more costly metal tin. It is not as durable as the tinned sheets, but is somewhat cheaper.

The best plates, both for tinning and for ternes, are made of charcoal iron; which, being tough, bears bending better. Coke is used for cheaper plates, but inferior as regards bending. In giving orders, it is important to specify whether charcoal plates or coke ones are required; also whether *tinned* plates, or *ternes*.

Tinned and leaded sheets of Bessemer and other cheap **steel**, are now much used. They are sold at about the price of charcoal tin and terne plates.

There are also in use for roofing, certain compound metals which resist tarnish better than either lead, tin, or zinc; but which are so fusible as to be liable to be melted by large burning cinders falling on the roof from a neighboring conflagration.

A roof covered with tin or other metal should, if possible, slope not much *less* than five degrees, or about an inch to a foot; and at the eaves there should be a sudden fall into the rain-gutter, to prevent rain from backing up so as to overtop the double-groove joint *s*, and thus cause leaks. Where coal is used for fuel, tin roofs should receive two coats of paint when first put up, and a coat at every 2 or 3 years after. Where wood only is used, this is not necessary; and a tin roof, with a good pitch, will last 20 or 30 years.

Two good workmen can put on, and paint outside, from 250 to 300 sq ft of tin roof, per day of 8 hours.

Tinned iron plates are sold by the **box.** These boxes, unlike glass, have *not* equal areas of contents. They may be designated or ordered either by their names or sizes. Many makers, however, have their private brands in addition; and some of these have a much higher reputation than others.

Table of Tinned and Terne Plates.

Caution.—Boxes often contain considerably less weight of tin plate than the table requires; the plates being rolled thin and plated thin, in order to enable mechanics to get pay for more material than they furnish.

The *marks* indicate the *thicknesses*, approximately as follows:

Sheets of larger size may be made to special order; those of tinned iron, in England; but leaded ternes are made in Philada also, and elsewhere

A box of 225 sheets of 13¾ by 10 contains 214.84 sq ft, but, allowing for overlapping, it will cover but about 150 sq ft of roof; even without any allowance for the waste which occurs in cutting away portions in order to fit at angles, &c.

To find the area of roof covered by any sheet, first deduct 2 ins from its width, and 1 inch from its length.

Zinc, in sheets, and laid in the same manner as slates, is much used in some parts of Europe for roofing. By exposure to the weather, it soon becomes covered by a thin film of white oxide, which protects it from further injury, and renders the roof very durable. Corrugated sheet zinc is also used. See Galvanized Sheet Iron.

Zinc sheets are usually about 3 ft by 7 or 8 ft. The gauge differs from that of iron; thus No 13 is .032 of an inch thick, or 1 22 lbs per sq ft; No 14 = .035 inch, and 1 35 lbs; No 15 = .042 inch, and 1 49 lbs, No 16 = 049 inch, and 1.62 lbs per sq ft. Any of these numbers may be used on roofs, for which purpose it should be very pure.

Water kept in zinc vessels is said to become injurious to health; and recently an outcry has on that account arisen against galvanized-iron service-pipes in dwellings. Yet such have been in use for many years in New England, Philada, and elsewhere, without as yet any deleterious effects. This is possibly owing to the fact that service-pipes being short, the water is usually all drawn through them several times a day; and hence does not remain in contact with the zinc or lead long enough to acquire a poisonous character. In taking possession of a house in which the water has remained stagnant in the service pipes for some considerable time, such water should all be run to waste; otherwise sickness may ensue from its use.

Roof copper is usually in sheets of 2½ feet × 5 feet; or 12½ square feet, weighing 10 to 14 lbs per sheet; and is laid on boards.* No solder is used in the horizontal joints as it is in tin roofs; but both the horizontal and the sloping joints are formed by only overlapping and bending the sheets, much as shown by the figs on page 1208; except that the horizontal joints are bent or locked together, and then flattened down close.

Lead service pipes for single dwellings in Philadelphia are usually of from ½ inch bore, wt 1 to 2½ lbs; to ⅝ inch bore, wt 1½ to 3 lbs per ft run, according to head. They **rarely burst** from sudden closing of stopcocks; but sometimes do so from the freezing of the contained water.

***To which it is held by copper cleats;** as at Fig y, page 1208.

Average ultimate tensile strength of Metals.

The ultimate tensile or pulling load per square inch of any material is frequently called its *constant*, *coefficient*, or *modulus* of tension, or of tensile strength.	Pounds per sq inch.	Tons per sq in.
Antimony, cast	1000	.45
Bismuth, cast	3200	1 4
Brass, cast 8 to 13 tons, say 18000 to 29000 lbs	23500	10 5
" wire, unannealed or hard, 80000. Annealed	49000	22
Bronze, phosphor wire, hard, 150000. Annealed	63000	28.1
Copper, cast 18000 to 30000	24000	10 7
" sheet	30000	13 4
" bolts, 28000 to 38000	33000	14.7
" wire (annealed 16 tons); unannealed	60000	26.8
Gold, cast	20000	8.9
" wire, 25000 to 30000	27500	12 3
Gun metal of copper and tin, 23000 to 55000	39000	17.4
" " cast iron, U. S. ordnance, 36000 to 40000.	38000	17
Iron, cast, English.........13400 to 22400	17900	8
" " ordinary pig..13000 to 16000	14500	6.47
American cast iron averages one-fourth more than the above.		
Average cast iron, when sound, stretches about .00018; or 1 part in 5555 of its length; or ⅛ inch in 57.9 ft. for every ton of tensile strain per sq inch, up to its elastic limit, which is at about ½ its break-strain. The extent of stretching, however, varies much with the quality of the iron, as in wrought-iron.		
Cast, malleable, annealed, 18 to 25 tons	48160	21.5
Iron and Steel, rolled.—See pp 751 to 754, 1150 to 1156.		
Lead, cast, 1700 to 2400 by author	2050	0 92

" wire	7000	3.1
Zinc, cast...3000 to 3700; (the last by author)	3350	1.5

Large bars of metal bear less per sq inch than small ones.

Iron bars re-rolled cold have tensile strength increased 25 to 50 per ct, with no increase of density. They are said to lose this strength if reheated.

The use of lead in masonry joints. See pp 634 and 1213. Under pressures usually less than the crushing stress of the stone, the lead flows laterally, and, by means of its friction with the stone, exerts, upon the latter, a tearing action normal to the pressure and tending to split the stone into prisms whose axes form slight angles with the line of pressure. This of course greatly weakens the stone.

Sheet lead is sometimes placed in the joints of stone columns, with a view to equalize the pressure, and thus increase the strength of the column. But experiments have proved that the effect is directly the reverse, and that the column is *materially weakened* thereby. See pp 634 and 1212.

Average crushing load for Metals.

It must be remembered that these are the loads for pieces but two or three times their least side in height. As the height increases, the crushing load diminishes.

	Pounds per sq inch	Tons per sq. inch.
Cast Iron, usually. It is usually assumed at 100000 lbs, or say 45 tons per sq inch. Its crushing strength is usually from 6 to 7 times as great as its tensile. Within its average elastic limit of about 15 tons per sq inch average cast iron shortens about 1 part in 5555, or ⅛ inch in 58 ft under each ton per sq inch of load, or about twice as much as average wrought iron. Hence at 15 tons per sq inch it will shorten about 1 part in 370; or full ⅛ inch in 4 feet. Different cast irons may however vary 10 to 15 per ct either way from this.	85000 to 125000	38 to 56
U. S. Ordnance, or gun metal; Some	175000	78.1
Wrought iron, within elastic limit	22400 to 35840	10 to 16
Its elastic limit under pressure averages about 13 tons per sq inch. It begins to shorten perceptibly under 8 to 10 tons, but recovers when the load is removed. With from 18 to 20 tons, it shortens *permanently*, about $\frac{1}{80}$th part of its length; and with from 27 to 30 tons, about $\frac{1}{16}$th part, as averages. The crushing weights therefore in the table are not those which absolutely mash wrought iron entirely out of shape, but merely those at which it yields too much for most practical building purposes. About 4 tons per sq inch is considered its average safe load, in pieces not more than 10 diams long; and will shorten it ⅛ inch in 30 ft. average	29120	13
Brass, reduced $\frac{1}{10}$th part in length, by 51000; and ½ by	165000	73.6
Copper, (cast,) crumbles	117000	52.2
(wrought) reduced ⅛th part in length, by	103000	46.0
Tin, (cast,) reduced $\frac{1}{16}$th in length, by 8800; and ⅓ by	15500	6.92
Lead, (cast,) reduced ½ of its length, by 7000 to 7700		3.28

Ultimate average crushing loads in tons, per square foot, for stones, &c. The stones are supposed to be ON BED, and the heights of all to be from 1.5 to 2 times the least side Stones generally begin to crack or split under about one-half of their crushing loads. In practice, neither stone nor brickwork should be trusted with more than ⅙ to $\frac{1}{10}$th of the crushing load, according to circumstances. **When thoroughly wet** some absorbent sandstones lose fully half their strength.

Crushing height of Brick and Stone.

If we assume the wt of ordinary brickwork at 112 lbs per cub ft, and that it would crush under 30 tons per sq ft, then a vert uniform column of it 600 ft high, would crush at its base, under its own wt. Caen stone, weighing 130 lbs per cub ft, would require a column 1376 ft high to crush it. Average sandstones at 145 lbs per cub ft, would require one 4158 ft high; and average granites, at 165 lbs per cub ft, one of 8145 feet. But stones begin to crack and splinter at about half their ultimate crushing load; and in practice it is not considered expedient to trust them with more than ⅙th to $\frac{1}{10}$th part of it, especially in important works; inasmuch as settlements, and imperfect workmanship, often cause undue strains to be thrown on certain parts.

The Merchants' shot-tower at Baltimore is 246 ft high; and its base sustains 6½ tons per sq ft. The base of the granite pier of Saltash bridge, (by Brunel,) of solid masonry to the height of 96 ft, and supporting the ends of two iron spans of 455 ft each, sustains 9½ tons per sq ft. The base of a brick chimney at Glasgow, Scotland, 468 ft high, bears 9 tons per sq ft; and Professor Rankine considers that in a high gale of wind, its leeward side may have to bear 15 tons The highest pier of Rocquefavour stone aqueduct, Marseilles, is 305 ft, and sustains a pressure at base of 13½ tons per sq ft.

---

* **Trials at St. Louis bridge,** by order of Capt James B. Eads, C. E., showed that some magnesian limestone did not yield under less than 1100 tons per sq ft. A column 8 ins high, 2 ins diam, shortened 0 00[illegible]5 inch under pressure; and recovered when relieved

Experiments made with the Govt testing machine at Watertown, Mass. 1882-3, gave 1400 tons per sq ft ultimate crushg load for white and blue marble from Lee, Mass. 700 for blue marble from Montgomery Co, Pa, 960 for limestone from Conshohocken, Pa, 500 for limestone from Indiana, 840 for red sandstone from Hummelstown, Pa, 260 to 1000 for yellow Ohio sandstone; Phila bricks, flatwise; hard, machine made, 350 to 700 tons; hand-made, 700 to 1300; pressed, machine-made, 450 to 580; Brickwork columns, 12 ins sq and 12 ins high; in lime, 100 tons; in cement, 150.

† Experiments by Col. Wm. Ludlow, U. S. A., with Govt testing machines in 1881, gave from [illegible] to 64 tons per sq ft for pure, hard ice; and 16 to 59 tons for inferior grades. The specimens ([illegible] and 12-inch cubes) compressed ⅛ to 1 inch before crushing.

STONE BEAMS.

Table of safe quiescent extraneous loads for beams of good building granite one inch broad, supported at both ends, and loaded at the center; assuming the safe load to be one-tenth of the breaking one; and the latter to be 100 lbs for a beam 1 inch square, and 1 foot clear span. The half weight of the beams themselves is here already deducted at 170 lbs per cub ft.

If uniformly distributed over the clear span, the safe extraneous loads will be twice as great as those in the table.

For good slate on bed the safe loads may be taken at about 3 times; **for good sandstone on bed** at about one-half; and for **good marble or limestone on bed** at about the same as those in the table.

CLAY. Specific Gravity.*

The specific gravity of the minerals (chiefly alumina silicates) composing clay, ranges ordinarily between 2.5 and 3; that of the solid portions of clays between 2.3 and 2.9.†

But the specific gravity of clay, *considered as a porous material,* varies between much wider limits, being affected by its porosity, the quantity of water contained, etc. See p. 211, ¶¶ 11 to 13. Thus, we find given values from 1.66 to 2.64; ‡ clay with gravel, 2.48; § potter's clay 1.8 to 2.1; dry clay, in lumps, loose, 1.0.

§ L. M. Haupt, Engineering Specifications and Contracts.

MORTAR, BRICKS, &c.

LIME MORTAR.

Art. 1. Mortar. The proportion of 1 measure of quicklime, either in irregular lumps, or ground, and 5 measures of sand, is about the average used for common mortar, by good builders in our principal Atlantic cities; and if both materials are good, and well mixed (or *tempered*) with clean water, the mortar is certainly as good as can be desired for such ordinary purposes as require no addition of hydraulic cement. The bulk of the mixed mortar will usually exceed that of the dry loose sand alone about $\frac{1}{8}$ part.

Quantity required. 20 cub ft, or 16 struck bushels of sand, and 4 cub ft, or 3.2 struck bushels of quicklime (the measures slightly shaken in both cases), will make abt $22\frac{1}{2}$ cub ft of mortar, sufficient to lay 1000 bricks of the ordinary average size of $8\frac{1}{4}$ by 4 by 2 ins, with the coarse mortar joints usual in interior house-walls, varying say from $\frac{3}{8}$ to $\frac{1}{2}$ inch. With such joints 1000 such bricks make 2 cubic yards of massive work. Nearly one third of the mass is mortar. For outside or showing joints, where a whiter and neater looking mortar is required, house-builders increase the proportion of lime to 1 in 4, or 1 in 3. For mortar of fine screened gravel, for cellar-walls of stone rubble, or coarse brickwork, 1 measure of lime to 6 or 8 of gravel, is usual, and the mortar is good. In average rough massive rubble, as in the foregoing brickwork, about one third the mass is mortar; consequently a cubic yard will require about as much as 500 such bricks, or 10 cubic feet (8 struck bushels) of sand, and 2 cub ft, or 1.6 bushels of quicklime. Superior, well scabbled rubble, carefully laid, will contain but about $\frac{1}{5}$ of its bulk of mortar; or $5\frac{1}{2}$ cub ft sand, and 1.1 cub ft lime, per cub yard.

For public engineering works, especially in massive ones, or where exposed to *dampness*, an addition should be made in either of the foregoing mortars, of a quantity of good **hyd cement,** equal to about $\frac{1}{3}$ of the lime; or still better $\frac{1}{3}$ of the lime should be omitted, and an equal measure of cement be substituted for it. **If exposed to water while quite new,** use little or no lime outside.

With bricks of $8\frac{1}{4}$ by 4 by 2 ins, the following are the **quantities of mortar and of bricks for a cubic yard of massive work.**

Thickness of Joints.	Proportion of Mortar in the whole mass	No. of Bricks per cub yard.	No. of Bricks per cub foot.
$\frac{1}{8}$ inch	about $\frac{1}{9}$	638	23.63
$\frac{1}{4}$ "	" $\frac{1}{4}$	574	21.26
$\frac{3}{8}$ "	" $\frac{3}{10}$	522	19.33
$\frac{1}{2}$ "	" $\frac{1}{3}$	475	17.60
$\frac{5}{8}$ "	" $\frac{4}{10}$	433	16.04

In estimating for bricks in massive work, **allow 2 or 3 per ct for waste;** and in common buildings, 5 per ct, or more. Much of the waste is incurred in cutting bricks to fit angles, &c. In Philadelphia a barrel of lump lime is allowed for 1000 bricks; or for 2 perches (25 cub ft each) of rough cellar-wall rubble. Somewhat less mortar per 1000 is contained in thin walls, than in massive engineering structures, because the former have proportionally more outside face, which does not require to be covered with mortar, but thin walls involve more waste while building; so that both require about the same quantity of materials to be provided. Careful experiments show that mortar becomes harder, and more adhesive to brick or stone, if the proportion of lime is increased. Hence, on our public works the proportion of one measure of quicklime to 3 of sand, is usually specified, but probably never used.

Lime is usually sold in lump, by the barrel, of about 230 lbs net, or 250 lbs gross. **A heaped bushel** of lump lime averages about 75 lbs. **Ground quicklime,** loose, averages about 70 lbs per struck bushel; and 3 bushels loose just fill a common flour barrel, but from 3.5 to 3.75 bushels, or 245 to 260 lbs can readily be compacted into a barrel.

General remarks on mortar and lime. On too great a proportion of our public works, the common lime mortar may be seen to be rotten and useless, where it has been exposed to moisture; which will be carried by the capillary action of earth to several feet above the natural surface, or as far below the artificial surface of embankments deposited behind abutments, retaining-walls, &c. The same will frequently be seen in the soffits of arches under embankments. *Common lime mortar, thus exposed to constant moisture, will never harden properly.* Even when very old and hard, it absorbs water freely. *Cement also does so, but hardens.*

Brickdust, or burnt clay, improves common mortar; and makes it hydraulic. In localities where sand cannot be obtained, burnt clay, ground, may be substituted; and will generally give a better mortar.

Protection of quicklime from moisture, even that of the air, is absolutely essential, otherwise it undergoes the process of **air-slacking,** or

spontaneous slacking, by which it becomes reduced to powder as when slacked by water as usual, but without heating, and with but little swelling. As this air slacking requires from a few months to a year or more, depending on quality and exposure, it gives the lime time to absorb sufficient carbonic acid from the air to injure or destroy its efficacy. But **quicklime will keep good for a long time** if first ground, and then well packed in air-tight barrels. The grinding also breaks down refractory particles found in all limes and which injure the mortar by not slacking until it has been made and used. For the same reason it is better that lime should not be made into mortar as soon as it is slacked, but be allowed to remain slacked for a day or two (or even several) protected from rain sun and dust

Lime slacked in great bulk may char or even set fire to wood.

Lime paste and mortar will keep for years, and improve, if well buried in the earth. Also for months if merely covered in heaps under shelter, with a thick layer of sand. The paste shrinks and cracks in drying, but the sand in mortar prevents this.

As approximate averages varying much according to the character and degree of burning of the limestone; and to the fineness or coarseness of the sand, one measure of good quicklime, either in lump, or ground. If wet with about ⅓ a measure of water, will within less than an hour, slack to about 2 measures of dry powder. And if to this powder there be added about ⅔ more measures of water, and 3 measures of dry sand, and the whole thoroughly mixed, the result will be about 3⅓ measures of mortar. Or the same slacked dry powder, with about 1 measure of water, and 5 measures of sand, will make about 5⅔ measures of mortar. In both cases the bulk of the mortar will be about ⅓ part greater than that of the dry sand alone If ⅔ of a measure of water be used for slacking, the result, instead of a dry powder, will be about 1⅓ measures of stiff paste, or with 1 whole measure of water for slacking, the result will be about 1⅓ measures of thin paste, of about the proper consistence for mixing with the sand. Very pure, *fat* limes, slack quickly, and make about from 2 to 3 measures of powder; while poor, *meagre* ones, require more time, and swell less Slow slacking, and small swelling, in case the lime has been properly burnt, are not in general bad properties; but on the contrary, usually indicate that it is to some extent hydraulic. In this case it makes a better mortar, especially for works exposed to moisture, or to the weather. Very pure limes are the worst of all for such exposures; or are bad *weather-limes;* and in important works, should never be used without cement.

Shell lime appears to be about the same as that from the purest limestones; but that from chalk is still more inferior and will not bear more than about 1½ measures of sand; its mortar never becomes very hard. Madrepores (commonly called coral) appear to furnish a lime intermediate between those of chalk and limestone They require to be but moderately burnt.

The average weight of common hardened mortar is about 105 to 115 lbs per cub ft.

Grout is merely common mortar made so thin as to flow almost like cream. It is intended to fill interstices left in the mortar-joints of rough masonry; but unless it contains a large amount of cement, it is probably entirely worthless; since the great quantity of water injures the properties of lime; and moreover, its ingredients separate from each other; the sand settling below the lime. Besides this, it will never harden thoroughly in the interior of thick masses of masonry; indeed, the same may probably be said of any common lime mortar. In such positions, it has been found to be perfectly soft, after the lapse of many years.

Both the sand and the water for lime mortar, should be **free from clay and salt.** The clay may be removed by thorough washing; but it is extremely difficult to get rid of the salt from seashore sand, even by repeated washings. Enough will generally remain to keep the work damp, and to produce efflorescences of nitre on the surface, whether with lime, or with cement mortar. Slacking by salt water gives less paste than fresh.

Mortar should not be mixed upon the surface of clayey ground, but a rough board, brick, or stone platform should be interposed. Pit sand sifted from decomposed gneiss, and other allied rocks, is excellent for mortar; its sharp angles making with the lime a more coherent mass than the rounded grains of river or sea sand. Mortar should be applied wetter in hot than in cold weather; especially in brickwork; otherwise the water is too much absorbed by the masonry, and the mortar is thereby injured.

The tenacity, or cohesive strength, that is, the resistance to a pull of good common lime mortar of the usual proportions of lime and sand, and 6 months old, is about from 15 to 30 lbs per sq inch; or .96 to 1.9 tons per sq ft. With less sand, or with greater age, it will be stronger.

The crushing strength of good common mortar 6 months old is from 150 to 300 lbs per sq inch, or 9.7 to 19.3 tons per sq foot

The sliding resistance, or that which common mortar opposes to any force tending to make one course of masonry slide upon another, is stated by Rondelet, to be but 5 lbs per sq inch; or about one third of a ton per sq ft. in mortar 6 months old.

Transverse strength of good common mortar 6 months old. A bar 1 inch square and 12 ins clear span, breaks with a center load of 4 to 8 lbs.

The lime in mortar decays wood rapidly, especially in close, damp situations. Still the soaking of timber for a week or two in a solution of quicklime in water appears to act as a preservative. **Iron,** so completely embedded in mortar as to exclude air and moisture, has been found perfect after 1400 years; but if the mortar admits moisture the iron decays So, probably, with other metals.

The adhesion to common bricks, or to rough rubble at any age will average about ⅔ of the cohesive strength at the same age; or say 12 to 24 lbs per sq inch, or .75 to 1.5 ton per sq ft at 6 months old. If care be taken to exclude dust entirely, by dipping each brick into water before laying it, or by sprinkling the stone by a hose, &c, the adhesion will be increased. On the other hand, much dust may almost prevent any adhesion at all. The precaution of wetting is especially necessary in very hot weather to prevent the warm bricks or stone from **killing the mortar** by the rapid absorption and evaporation of its water. **The adhesion to very smooth hard pressed bricks,** or to smoothly dressed or sawed stone is considerably less.

BRICKS.

Art. 2. Bricks, size, weight, &c. A brick 8.25 × 4 × 2 ins contains 66 cub ins; or 26.2 bricks to a cub ft; or 707 bricks to a cub yard.

In ordering a large number, a minimum limit of dimension should be specified, in order to prevent fraud. A brick ¼ inch less each way than the above, contains but 52.5 cub ins; thus requiring full 25 per cent more bricks to do the same work, and 25 per ct more cost for laying, which is generally paid by the 1000.

The weight of a good common brick, 8.25 × 4 × 2 ins, will average about 4.5 ℔s; or 118 ℔s per cub ft = 3186 ℔s or 1.42 tons per cub yard; or 2.01 tons per 1000. A good pressed brick of the same size will average about 5 ℔s, = 131 ℔s per cub ft = 3537 ℔s or 1.58 tons per cub yd; or 2.23 tons per 1000. Since the weight of hardened mortar averages but little less than that of good common brick, we may for ordinary calculations assume the **weight of brickwork,** with common bricks, at 1.4 tons per cub yard, or 116 ℔s per cub ft; and, with pressed brick, at 1 56 tons per cub yd, or 129 ℔s per cub ft.

In water, either brick will in a few minutes **absorb** from ½ to ¾ ℔ of water; or 0.1 to one-seventh of the weight of a pressed brick, or ¼ to one-third of its bulk.

Number of bricks 8¼ × 4 × 2, required per sq foot of wall, allowing for the usual waste in cutting bricks to fit corners, jambs, &c.:

Wall 8¼ ins, or 1 brick	.....14 bricks	Wall 21½ ins, or 2½ brick	.....35 bricks
" 12¾ " or 1½ "	.....21 "	" 25¾ " or 3 "	.....42 "
" 17 " or 2 "	.....28 "		

Laying, per day. A bricklayer, with a laborer to keep him supplied with materials, will, in common house walls, lay on an average about 1500 bricks per day of 10 working hours. In the neater outer faces of back buildings, from 1000 to 1200; in good ordinary street fronts, 800 to 1000; or of the very finest lower story faces used in street fronts, from 150 to 300, depending on the number of angles, &c. In plain massive engineering work, he should average about 2000 per day, or 4 cub yds; and in large arches, about 1500, or 3 cub yds.

Since bricks shrink about $\frac{1}{12}$ part of each dimension in drying and burning, the moulds should be about $\frac{1}{12}$ part larger each way than the burnt brick is intended to be. Good well-burnt bricks will ring when two are struck together.

At the brick-yards about Philadelphia, a brick-moulder's work is 2333 bricks per day; or 14000 per week. He is assisted by two boys, one of whom supplies the prepared clay, moulding sand, and water; while the other carries away the bricks as they are moulded. A fourth person arranges them in rows for drying. About ¾ of a cord, or 96 cub ft of wood, is allowed per 1000 for burning. Where coal is used, the kilns are fired up with anthracite, and the finishing is done with bituminous. One ton of coal, in all, makes 4500 bricks.

For paving sidewalks the bricks are laid on a 6-inch layer of gravel, which should be free from clay, and well consolidated. With bricks of 8¼ × 4 × 2 ins, with joints from ⅛ to ¼ inch wide, a square yard requires, flatwise, 38 bricks; edgewise, 73; endwise, 149. An average workman, with a laborer to supply the bricks and gravel, will in 10 hours lay about 2000 bricks; or 53 sq yds flat, 27 edgewise, 13 endwise. When done, sand is brushed into the joints.

Art. 3. The crushing strength of bricks of course varies greatly. A rather soft one will crush under from 450 to 600 ℔s per sq inch; or about 30 to 40 tons per sq ft; while a first-rate machine-pressed one will require about 200 to 400 tons per sq ft, or about the crushing limit of the best sandstone; two-thirds that of the best marbles or limestones; or ½ that of the best granites, or roofing slates. But masses of **brickwork** crush under much smaller loads than single bricks. In some English experiments, small cubical masses, only 9 inches on each edge, laid in cement, crushed under 27 to 40 tons per sq ft. Others, with piers 9 ins square, and 2 ft 3 ins high, in cement, only two days after being built, required 44 to 62 tons per sq ft to crush them. Another, of pressed brick, in best Portland cement, is said to have withstood 202 tons per sq ft; and with common lime mortar only ¼ as much.

It must, however, be remembered, that cracking and splitting usually commence under about one-half the crushing loads. To be safe, the load should not exceed ⅛ of the crushing one; and so with stone. Moreover, these experiments were made upon low masses; and the strength decreases with the proportion of the height to the thickness.

The pressure at the base of a brick shot-tower in Baltimore, 246 feet high, is estimated at 6½ tons per sq ft; and in a brick chimney at Glasgow, Scotland, 468 feet high, at 9 tons. Professor Rankine calculates that in heavy gales this is increased to 15 tons, on the leeward side.

With our present imperfect knowledge on this subject, it cannot be considered safe to expose even first-class pressed brickwork, *in cement*, to more than 12 or 15 tons per sq ft, or good hand-moulded, to more than two-thirds as much.

Tensile strength of brick, 40 to 400 lbs per sq inch; or 2.6 to 26 tons per sq ft.

The English rod of brickwork is 306 cub feet, or $11\frac{1}{3}$ cub yards; and requires about 4500 bricks of the English standard size, with about 75 cub ft of mortar. The English *hundred of lime*, is a cub yd

Frozen mortar. There is risk in using common mortar in cold weather If the cold should continue long enough to allow the frozen mortar to set well, the work may remain safe, but if a warm day should occur between the freezing and the setting of the mortar, the sun shining on one side of the wall may melt the mortar on that side, while that on the other side may remain frozen hard. In that case, the wall will be apt to fall; or if it does not, it will at least always be weak; for mortar that has partially set while frozen, if then melted, will never regain its strength. By the writer's own trials hydraulic cements seemed not to be injured by freezing.

Experiments for rendering brick masonry impervious to water. Abstract of a paper read before the American Society of Civil Engineers, May 4, 1870, by William L. Dearborn, Civil Engineer, member of the Society

The face walls of the Back Bays of the Gate-houses of the new Croton reservoir, located north of Eighty sixth Street, in Central Park, were built of the best quality of hard-burnt brick, laid in mortar composed of hydraulic cement of New York, and sand mixed in the proportion of one measure of cement to two of sand. The space between the walls is 4 ft and was filled with concrete. The face walls were laid up with great care and every precaution was taken to have the joints well filled and insure good work They are 12 ins thick, and 40 ft high; and the Bays when full generally have 36 ft of water in them.

When the reservoir was first filled, and the water was let into the Gate-houses it was found to filter through these walls to a considerable amount. As soon as this was discovered, the water was drawn out of the Bays, with the intention of attempting to remedy or prevent this infiltration After carefully considering several modes of accomplishing the object desired, I came to the conclusion to try "Sylvester's Process for Repelling Moisture from External Walls"

The process consists in using two washes or solutions for covering the surface of brick walls; one composed of Castile soap and water, and one of alum and water. The proportions are three quarters of a pound of soap to one gallon of water; and half a pound of alum to four gallons of water both substances to be perfectly dissolved in the water before being used

The walls should be perfectly clean and dry; and the temperature of the air should not be below 50 degrees Fahrenheit, when the compositions are applied

The first, or soap wash, should be laid on when at boiling heat, with a flat brush taking care not to form a froth on the brickwork This wash should remain twenty-four hours, so as to become dry and hard before the second or alum wash is applied, which should be done in the same manner as the first The temperature of this wash when applied may be 60° or 70°, and it should also remain twenty-four hours before a second coat of the soap wash is put on, and these coats are to be repeated alternately until the walls are made impervious to water.

The alum and soap thus combined form an insoluble compound, filling the pores of the masonry and entirely preventing the water from penetrating the walls.

Before applying these compositions to the walls of the Bays, some experiments were made to test the absorption of water by bricks under pressure after being covered with these washes, in order to determine how many coats the wall would require to render them impervious to water.

To do this a strong wooden box was made put together with screws, large enough to hold 2 bricks; and on the top was inserted an inch pipe forty feet long.

In this box were placed two bricks after being made perfectly dry, and then covered with a coat of each of the washes, as before directed, and weighed. They were then subjected to the pressure of a column of water 40 feet high, and, after remaining a sufficient length of time, they were taken out and weighed again, to ascertain the amount of water they had absorbed.

The bricks were then dried, and again coated with the washes and weighed, and subjected to pressure as before; and this operation was repeated until the bricks were found not to absorb any water. Four coatings rendered the bricks impenetrable under the pressure of 40 ft head

The mean weight of the bricks (dry) before being coated, was $3\frac{1}{4}$ lbs; the mean absorption was one-half pound of water. An hydrometer was used in testing the solutions

As this experiment was made in the fall and winter, (1863,) after the temporary roofs were put on to the Gate-house, artificial heat had to be resorted to, to dry the walls and keep the air at a proper temperature. The cost was 10.06 cts per sq ft. As soon as the last coat had become hard the water was let into the Bays, and the walls were found to be perfectly impervious to water, and they still remain so in 1870, after about $6\frac{1}{2}$ years.

BRICK ARCH (FOOTWAY OF HIGH BRIDGE). The brick arch of the footway of High Bridge is the arc of a circle 29 ft 6 in radius; and is 12 in thick; the width on top is 17 ft; and the length covered was 1381 ft.

The first two courses of the brick of the arch are composed of the best hard burnt brick laid edgewise in mortar composed of one part, by measure, of hydraulic cement of New York, and two parts of sand The top of these bricks, and the inside of the granite coping against which the two top courses of brick rest was, when they were perfectly dry, covered with a coat of asphalt one-half an inch thick, laid on when the asphalt was heated to a temperature of from 360° to 518° Fahrenheit.

On top of this was laid a course of brick flatwise, dipped in asphalt, and laid when the asphalt was hot; and the joints were run full of hot asphalt

On top of this a course of pressed brick was laid flatwise in hydraulic cement mortar, forming the paving and floor of the bridge. This asphalt was the Trinidad variety: and was mixed with 10 per cent, by measure, of coal tar; and 25 per cent of sand. A few experiments for testing the strength of this asphalt, when used to cement bricks together, were made, and two of them are given below.

Six bricks, pressed together flatwise with asphalt joints, were, after lying six months, broken The distance between the supports was 12 ins; breaking weight, 900 lbs, area of single joint, $28\frac{1}{2}$ sq ins. The asphalt adhered so strongly to the brick as to tear away the surface in many places.

Two bricks pressed together end to end, cemented with asphalt, were, after lying 6 months, broken. The distance between the supports was 10 ins area of joint, 8¼ sq ins; breaking weight, 150 lbs.

The area of the bridge covered with asphalted brick, was 23065 sq ft. There was used 94200 lbs of asphalt, 33 barrels of coal tar, 10 cub yds of sand, 93800 bricks.

The time occupied was 109 days of masons, and 148 days of laborers. Two masons and two laborers will melt and spread, of the first coat, 1650 sq ft per day. The total cost of this coat was 5.25 cents per sq ft, exclusive of duty on asphalt. There were three grooves, 2 ins wide by 4 ins deep, made entirely across the brick arch, and immediately under the first coat of asphalt, dividing the arch into four equal parts. These grooves were filled with elastic paint cement.

This arrangement was intended to guard against the evil effects of the contraction of the arch in winter; as it was expected to yield slightly at these points, and at no other point; and then the elastic cement would prevent any leakage there.

The entire experiment has proved a very successful one, and the arch has remained perfectly tight.

In proposing the above plan for working the asphalt with the brickwork, the object was to avoid depending on a large continued surface of asphalt, as is usual in covering arches, which very frequently cracks from the greater contraction of the asphalt than that of the masonry with which it is in contact, the extent of the asphalt on this work being only about one-quarter of an inch to each brick. This is deemed to be an essential element in the success of the impervious covering."

A cheap and effective process for preventing the percolation of water through the arches of aqueducts, and even of bridges is a great desideratum. Many expensive trials with resinous compounds have proved failures. Hydraulic cement appears to merely diminish the evil. Much of the trouble is probably due to cracks produced by changes of temperature.

The **white efflorescence** so common on walls, especially on those of brick, is due to the presence of soluble salts in the bricks and mortar. These are dissolved, and carried to the face of the wall, by rain and other moisture. Sulphate of magnesia (Epsom Salt) appears to be the most frequent cause of the disfiguration. In many places mortar lime is made from dolomite, or *magnesian* limestone, which often contains 30 per cent or more of magnesia; which also occurs frequently in brick clay. Coal generally contains sulphur, most frequently in combination with iron, forming the well-known "iron pyrites". The combustion of the coal, as in burning the limestone or clay, in manufactures, in cooking etc, converts the sulphur into sulphurous acid gas, which, when in contact with magnesia and air, as in the lime or brick kiln, or in the finished wall or chimney, becomes sulphuric acid and unites with the magnesia, forming the soluble sulphate. We are not aware of any remedy that will prevent its appearance under such circumstances; but the formation of the sulphate may be prevented by the use of limestone and brick-clay free from magnesia.

MORTAR.

Cement.

For experiments, see p 1303.

For specifications, see pp 1229, 1232, 1234, 1352.

For Concrete, see pages 1252, etc.

For abbreviations, symbols and references, see p 1251.

1. The property of setting and hardening under water is called **hydraulicity;** and cements, which harden under water, are called **hydraulic cements;** or, more briefly, **cements. For behavior** of cement **when mixed with water,** with or without sand, see **Mortar,** p 1243.

Materials.

2. The elements, chiefly concerned in the action of lime and cem mortars, are—

Calcium,	Ca	Oxygen, O.
Aluminum,	Al	
Carbon,	C	
Silicon,	Si	
Hydrogen,	H	

3. Oxygen combines with each of the others, forming **oxides.** Thus:

Calcium oxide, CaO, is lime;
Aluminum sesqui-oxide, Al_2O_3,* is alumina;
Carbon dioxide, CO_2, is carbonic acid;
Silicon dioxide, SiO_2, is silica, or silicic acid;†
Hydrogen monoxide, H_2O, is water.

4. The materials most used in the manufacture of cements are either (a) calcareous, (b) argillaceous, or (c) both calcareous and argillaceous.

(a) Calcareous (rich in lime carbonates).

Limestone, a lime carbonate, or combination of lime and carbonic acid $CaO + CO_2$ or $CaCO_3$. Marble is limestone.

Dolomite, or **magnesian limestone,** containing about 45 per cent of magnesia carbonate, $MgO.\ CO_2$. Where strata of limestone and dolomite adjoin, the rock varies in composition between the two, containing percentages of magnesia carbonate varying from 0 to 45.

Chalk, a soft limestone, composed of remains of marine shells.

Marl, a soft and impure hydrated ‡ lime carbonate, precipitated from still water and found in the beds and banks of extinct or existing lakes.

Alkali waste, lime carbonate, precipitated, as a waste product, in the manufacture of caustic soda.

Coral. See ¶ 5

(b) Argillaceous (rich in alumina silicates).

Clay (including argillaceous minerals in general), an alumina silicate, or combination of alumina and silicic acid, $Al_2O_3 + SiO_2$.

Shale and slate, clay, solidified by geological processes.

Puzzolana, or pozzuolana, a volcanic slag, found at Puzzuoli, or Pozzuoli, near Mount Vesuvius, an impure alumina silicate.

Blast furnace slag, practically an artificial puzzolana.

Brick-dust. See ¶ 6.

(c) Rich in both **lime carbonate and alumina silicate.**

Cement rock is argillaceous (clayey) limestone. The alumina silicate usually ranges from 13 to 35 %. There is generally a considerable percentage of magnesia carbonate, amounting sometimes to 25 %.

5. A soft coral rock, from the reefs near Colon, **Panama,** mixt with clay and silt brought down by the Chagres river, or with "a pumiceous rhyolite tuff," found on the Isthmus, or with both, and crushed, burned and tested at the Lehigh Valley Testing Laboratory, at Allentown, Pa., gave a

---

* The subscripts indicate the combining ratios of the several elements. Thus, in alumina, Al_2O_3 means a compound of 2 atoms of aluminum with 3 of oxygen.

† Quartz is silica; and most of the sand, used in mortar, is quartz sand.

‡ Hydrated; containing chemically combined water.

uniform cement, comparing favorably with average standard brands of Lehigh cement. The coral rock is "a remarkably pure lime carbonate." The Chagres clay and silt are "rather low in silica, but contain a relatively large amount of iron as compared with alumina." The tuff "is of approximately the same composition as the argillaceous materials used in the Lehigh district of Pennsylvania." (Ernest Howe, U. S. G S, E N, '07/Nov/21, p 544.) See ¶¶ 29, etc.

6. Mr. Ernest McCullough "mixed fine **brick dust and hydrated lime** together and made a fairly satisfactory cem for a small concrete job in a locality where Portland cem could not be obtained." (E N, '07/Nov/21, p 557.)

7. Lime. When limestone (without clay) is "burned," its CO_2 is driven off, and the remaining ("**quick**") **lime** has a strong affinity for water, absorbing it with such avidity as to develop heat sufficient to produce steam, the generation of which disintegrates and swells the mass. Combining thus with the water, the lime forms calcium hydrate, $CaO.H_2O$, or CaH_2O_2. This process is called **slaking** or **slacking**; and lime which has satisfied its affinity for water is called slaked (or slack) lime. When slaked lime is used as mortar, it gradually absorbs carbonic acid from the air, forming lime carbonate, the water being liberated and evaporated. Hardened lime mortar may thus be regarded as an artificial limestone.

Manufacture.

8. Cement. When alumina silicate, such as clay, in sufficient quantities, is "burned" with calcium carbonate, such as limestone, the burned product, called cement, is deficient in, or devoid of, the slacking property; but, on the other hand, when it is made into mortar, the combinations, formed between the elements of the lime, the alumina, the silica and the water, during the burning, and afterward in the mortar, are such that they readily proceed under water. Chemists differ as to the nature of these combinations, except that these constitute a process of crystallization, resulting chiefly in the formation of hydrated lime silicate and hydrated lime aluminate, which two compounds constitute the major portion of most cems.

Natural and Portland Cement.

9. In the manufacture of "**natural**" **cement**, cement rock, broken into lumps, is first calcined, at from 1000° to 1400° C (1800° to 2500° F) in a stationary kiln, in alternate layers with coal of about pea size, as fuel. It is then ground to a fine powder, and this is sometimes specially mixed, in order to increase its uniformity.

10. The qualities of nat cems vary widely, owing to diffs in the compositions of cem rocks found in diff localities.

11. The name **Rosendale,** originally and properly restricted to nat cems made in Ulster County, N Y, was at one time applied indiscriminately to American nat cems in general.

12. In Europe, quick-setting nat cems are called "**Roman cements.**"

13. Portland cement was so called on account of the resemblance of the hardened mortar to Portland stone, the oolitic limestone of Portland, England.

14. Portland cem **is made** from different combinations of the calcareous and argillaceous materials named in ¶ 4, and these require different preliminary treatments. Thus. hard rock is crushed; soft rock and clay are ground; marl and clay are mixed wet, and the marl is sometimes pumped to the mill. In any case, the resulting materials are dried and finely ground, mixed, and then calcined at a temperature of 1450° to 1550° C, or say 2600° to 2800° F, producing incipient vitrifaction, which consists of the chemical combination of the silica, alumina and lime, into a glassy clinker, essentially a lime silicate and aluminate. The resulting clinker is again ground to an impalpable powder, which is the finished product.

15. The proportions of the several materials are carefully adjusted. There is usually from 74 to 77.5 % lime carbonate, and about 20 % of alumina silicate and iron oxide. See ¶ 32.

16. Manipulation. The raw material is sometimes molded into bricks which are burned in a stationary kiln; but it is now more generally fed, as a fine powder, into the upper end of a nearly hor cyl (rotary kiln) 6 to 8 ft

in diam and from 60 to 100 ft or more in length. Coal dust, as fuel, is injected, by an air blast, into the other end; while most of the air, required for combustion, is admitted freely from the atmosphere thru other openings.

17. As in the case of lime, the **burning** drives off the carbonic acid and water, and more completely oxidizes any iron present.

18. The higher cost of Portland cement is due to the more careful selection of the materials and to the more elaborate and expensive treatment given them, resulting in the ultimate attainment of much greater strength and uniformity than are usually found in nat cems.

19. The improvements, which have been made in the manufacture of **Portland cement,** are driving out other makes. Owing to its greater sand-carrying capacity, it is often used, by contractors, even where the specifications permit the use of nat cem.

20. Overburning is liable to occur, if the material is deficient in lime ("over-clayed"). **Underburning** yields a soft brownish clinker, and weak, quick-setting cem, heating in water. Some cems, slow at first, become quicker after storage.

21. Portland Cement is used for structures subjected to severe or repeated stresses, for cases where high strgth must be attained in a short time, for concrete buildings, where water will be in contact with new work, for thin walls subject to water pres, and for work exposed to abrasion or to weather; while **natural cement** may be used in dry sheltered foundations under compressive loads not exceeding 75 lbs per sq inch and not imposed until 3 months after placing, for backing and filling in massive conc or stone masonry where wt and mass are desiderata, and for street and sewer foundations.

Puzzolana.

22. Slag cements (sometimes called **puzzolana** cements or puzzolana) are intimate mixtures of slaked lime and basic blast-furnace slag, both finely ground, and not calcined. As the slag leaves the blast-furnace, it is chilled and disintegrated by running it into water. A little soda is sometimes added, to hasten setting. Slag cem is not to be confounded with those *Portland* cems in which slag is one of the ingredients.

23. In dry air, the sulphides, contained in **Puzzolana cement,** oxidize, and cause superficial cracking. It sets more slowly than Portland, unless treated with soda. If so treated, the soda becomes carbonated under long storage, and the cem again becomes slow-setting. Since puzzolana cem, properly made, contains no free or anhydrous lime, it does not warp or swell, and requires less water than Portland; but, for permanency after placing, the finished work should be kept constantly moist. It is recommended for use in sea water, alone or mixed with Portland. Its mortar is tougher than Portland, but never becomes so hard. It should not be subjected to attrition or blows. (Report, Board of U S Engr officers, U. S., Prof'l Papers No 28, '01.)

24. Puzzolana cement is said to work well if used with 2 or 3 parts sand and not subjected to freezing weather. Its ingredients must be finely ground and intimately mixed. It is used where extreme strength and hardness are not required

Silica Cement.

25. Silica Cement, or sand cement, was originally made by mixing Portland cem with quartz sand (silica) and grinding the mixture to extreme fineness It was claimed that the cem thus became much more finely ground, and that "silica cement," containing one part Portland cem and three parts silica, could therefore carry, in mortar, nearly as much sand as could the pure cem alone; also that mortars, made with silica cem, were less permeable to water than those made with pure cem in the ordinary way.

26. Owing to the high cost of grinding the quartz sand, less refractory materials, such as **lime-stone,** are now substituted for it. The product, so obtained, is still called "silica cement," altho containing a less proportion of silica than Portland cem.

27. Silica cement mortar is said to work more smoothly under the trowel than that made with ordinary cems.

28. In the construction of a concrete lock at St. Paul, Minn., it was intended to use 1.5 volumes silica cem as equivalent to 1 vol Saylor's Port-

land; but experiments indicated that, at 6 mos, concrete, made with silica cem, was **as strong** as that made with **Portland.**

Other Cements.

29. White Portland cement, obtained by making certain modifications in the process of manufacture, is nearly colorless. It is suitable for making imitation marbles, etc., and capable of taking artificial coloring. It is higher in price than ordinary Portlands. See ¶ 44.

30. Iron ore cement ("Erz-cement"), Krupp Steel Co. In this cem, the argillaceous material of Portland cem is mostly replaced by iron oxide. The material is burned and ground as for Portland cem, ¶¶ 13, &c. Spec grav, 3.31. Slower setting than Portland. Sound. Low early strgths; but, in time, strgth far exceeds that of Portland. No trace of expansion or crackg in sea water under 15 atmospheres. (Wm. Michaelis, Jr., Western Soc Engrs, Aug 1907; S. B. Newberry, Cement Age, Jan 1907.)

31. Hydraulic lime is a name given to cems (much used in Europe) which, while to some extent hydraulic, do not contain enough of the hydraulic elements to prevent slaking. The slaking, however, is slower, and the swelling less, than with lime proper.

Composition.

32. Analyses of cements, in percentages.

In each group of three lines,
the *upper* line shows the *max* percentage.
" *middle* " " " *mean* "
" *lower* " " " *min* "

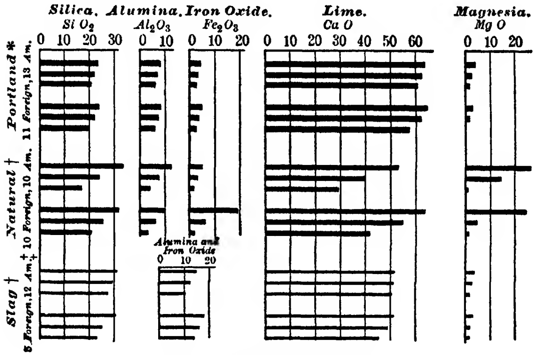

Fig 1. Analyses of Cements.

33. The ratio of the wt of alumina silicate to that of the lime, in a cem, is called its **hydraulic index.** Other things being equal, it may be used as an indication of the hydraulicity of the cem.

34. Thus, if a cem contains 30 % alumina silicate and 60 % lime, its hydraulic index is 30/60 = 0.50.

35. The hydraulic modulus is approximately the *reciprocal* of the hydraulic index; *i.e.*, the modulus is the ratio, by wt, of lime, to silica,

* Richard K. Meade, "Portland Cement," 1906, pp 16–17.
† E. C. Eckel, "Cements, Limes and Plasters," 1907, pp 253 etc., 667–8.
‡ 16 analyses of "Steel" (slag) cement, made by Illinois Steel Co., South Chicago, reported by Board of U. S. Engr Officers, 1900, gave practically the same avs, but with generally greater uniformity: silica, 29.9 to 27.8; alumina and iron, 12.1 to 11.1; lime, 52.1 to 50.3; magnesia, 3.0 to 1.6.

alumina and iron oxide. It is sometimes specified that the modulus, in Portland cement, shall be 1.7.

36. In natural cements, the modulus usually ranges from 0.667 to 1.667.

37. Mr. Spencer B. Newberry uses the ratio:

(lime — alumina) ÷ silica,

which he terms the **lime factor**, and which usually varies, in the raw material, betw 2.7 and 2.8, and, in the best commercial cems, betw 2.5 and 2.6.

38. Mr. Edwin C. Eckel (Cements, Limes and Plasters, p 170) suggests the

$$\textbf{Cementation index} = \frac{2.8s + 1.1a + 0.7i}{l + 1.4m}$$

where s, a, i, l and m are the percentages, by wt, of silica, alumina, iron oxide, lime and magnesia, respectively.

39. The most common **adulterants** of cem are ground limestone, lime, shale, slag and ashes; and Portland cem is sometimes adulterated with nat cem. Most of the adulterants commonly used are merely inert, and therefore only weaken the cem; but quick lime may do more serious mischief.

See Cement Mortar, ¶¶ 28, etc., p 1245.

Properties.

Fineness.

40. Fineness. Even in cem of standard fineness, the inner portions of the grains seem to remain inert. The finer the cem, the more sand it will carry and still produce a mortar of a given strength; but, in each case, there is a point where the cost of additional fineness offsets the additional advantage which may be gained.

41. Hence **fineness** is less important with **natural** than with **Portland** cem; for the cheapness of nat cem may render it advisable to use the cem in larger quantities, rather than pay for finer grinding, in order to secure the desired strgth.

42. Cements, ground to **extreme fineness,** in order to secure strgths beyond those of commercial products, set so quickly that they must be used immediately after adding water. (Wm. Michaelis, Jr., Western Soc of Engrs, Aug '07.)

43. The fineness of cement and sand is indicated as follows, where the large numerals represent the sieve numbers; the small numeral, to the left of each sieve number, represents the percentage retained upon that sieve; and the final small numeral, to the right of the last sieve number, represents the percentage passed by the last sieve. The sum of the small numerals = 100. Thus, ${}^{5}20\ {}^{15}30\ {}^{35}40^{45}$ means that 5 % were retained on a No. 20 sieve, 15 % on a No. 30, and 35 % on a No. 40, while the remaining 45 % passed the No 40 sieve.

Color.

44. Color. The lime silicates and aluminates, which constitute the cem proper, are colorless when pure. (See White Cement, ¶ 29.) The color of cems is therefore due to other matter which is unavoidably present, notably to the iron oxides, and may be affected by either beneficial, harmful or neutral ingredients. Hence, color, in itself, is of but little value as a guide to quality; but **variations in shade,** in a given kind of cem, may indicate diffs in the character of the rock or in the degree of burning. Thus, with nat cems, a light color generally indicates an inferior or underburned rock. A coarse-ground cem, light in color and wt, would be viewed with suspicion.

45. "With Portland cem, gray or greenish-gray is generally considered best; bluish gray indicates a probable excess of lime, and brown an excess of clay. Natural cems are usually brown, but vary from very light to very dark. Slag cem has a mauve tint—a delicate lilac." (Prof Ira O. Baker, "A Treatise on Masonry Construction," p 55.)

Weight.

46. Specific gravity and weight. See spec grav, pp. 1232, 1234. The sp gr of the solid particles of cem is not affected by fineness of grinding,

but is diminished by absorption of water and carbonic acid under exposure, and is therefore increased by drying. The sp gr of Portland cems may range from 2.9 to 3.25, ordinarily from 3 to 3.2; nat cems, 2.7 to 3.2; Puszolano cem, from 2.7 to 2.9.

47. The weight, per cu ft, of cem powder, is affected by exposure and by drying, as explained above, and is increased by compression, as in packing. It is reduced by fine grinding, the finer particles packing less closely. Faija found a loss, in wt, of about 6 % in a few days after grinding; 17 % in 6 mos, and 21 % in a year.

48. In a German Portland cem, Eliot C. Clarke found 90 lbs per cu ft when 40 % was retained on No. 120 sieve, and 75 lbs per cu ft when so finely ground that all passed the same sieve.

49. As a rude approximation, Portland cem is taken as weighing 100 lbs, nat cem 75 lbs, per cu ft.

Packages.

50. Owing to variations in the specific gravity of cems, there is corresponding variation in **sizes and weights** of packages and their contents. The trade practice is to sell a bbl of Portland cem as 400 lbs gross (including wt of bbl); nat, 300 lbs gross.

51. A Portland Cement barrel is 2 to 2.2 ft high, betw heads, 1.38 to 1.46 ft av diam. It weighs 21 to 29 lbs, and is lined with paper for ordinary transportation. Its capacity is 3.1 to 3.5 cu ft, but the cem, compressed into it, in packing, occupies 3.75 to 4.3 cu ft loose, and weighs 370 to 390 lbs. The bbl is not returnable.

52. A natural cement barrel weighs about 20 lbs. In the Western states it contains 265 lbs; in the Eastern states, 300 lbs, of cem.

53. "Domestic" barrels are used for shipment to all points in the U. S., with slight reinforcement for Gulf ports; **"standard export"** bbls for Mexico and the West Indies; **"special export barrels"** where specially severe treatment is expected.

54. The standard export barrel is of better stock than the "domestic," and is reinforced with cross pieces in the heads and with two iron hoops. It costs from 5 to 10 cts more than the "domestic" bbl, varying with cost of cooperage stock.

55. The special export barrel costs 10 to 15 cts more than the standard export bbl. It is all-hardwood, heavily hooped and reinforced, with wood cross-pieces in the heads, iron hoops, and clamps to hold the heads in place. A heavy waterproof lining is used instead of the heavy Manila paper used with the standard export bbl.

56. Most cem is now packed in "cloth" or paper bags, except for shipment by sea.

57. Cement bags are made of cloth (canvas or cotton duck) and of "rope Manila" paper. When empty, they measure about 17 × 28 ins. (See Digest of specification of the Am Soc for Testing Materials.) A "cloth" bag is usually charged to the purchaser at about 10 cts, and credited at about 7.5 cts when returned. **Paper bags** are charged at 2.5 cts each and are not returnable.

58. The use of **paper bags** obviates loss of time in emptying and returning bags, shortage on lost or damaged bags, and loss of cem in transit or by failure to empty bags completely; but paper bags are more likely to lose their entire contents by breakage, and pieces of broken bags may get into the work and weaken it.

59. For large work, cem has frequently been **shipped in cars in bulk,** with little loss or damage, provided the cars are carefully selected. This method is especially advantageous where the cem is tested at the mill, stored in "accepted bins," and shipped direct to the work, in sealed cars. The cars may be unloaded by automatic conveyors. Bags and bbls are often preferred as furnishing a convenient means for keeping account of the quantities of cem entering the work; but, in large operations, there should be no difficulty in arranging to keep such accounts with bulk shipments.

Age.

60. "Aging" consists in the slaking of the free lime remaining in the cem after burning. Good Portland cem is improved by a few weeks of

aging in dry air; and, if kept dry it deteriorates but slowly under even long storage; but nat cems usually suffer by aeration; and cems in general, being composed of compounds with a strong affinity for water, deteriorate if exposed to dampness. Hence, protection from moisture, even that of the air, is very essential for the preservation of cems, as well as of quicklime. With this precaution, the cem, altho it may require more time to set, than when fresher, does not otherwise very appreciably deteriorate in many months.

61. Storage, under pressure, tends to the caking of cems, which, therefore, does not necessarily indicate deterioration.

62. Restoration by reburning. Cems which have deteriorated by exposure, may be in great measure restored by reheating to redness.

63. If cem is **stored in warm places,** it is apt to "flash" when mixed with water, *i. e.*, to set much more rapidly than it should.

Testing.

See Digests of Specifications, A S C E, p 942; Engng Standards Comm of Gt Brit, p 940; Report of Board of U S Engr Officers, p 937.

64. *Thoro* ***chemical tests*** *of cem can of course be made only by expert chemists; but the following simple test may be made by the engineer. Treated with hydrochloric acid, "pure Port cem effervesces slightly, gives off some pungent gas, and gradually forms a bright yellow jelly, without sediment.* Powdered limestone or cem rock, mixed with the cem, causes violent effervescence, the acid giving off strong fumes until all the lime carbonate is decomposed, when the yellow jelly forms. Quartz sand remains undissolved. Reject cem containing these adulterants." Judson, "City Roads and Pavements." The presence of slag is generally indicated by the sulfur present, which causes a milky appearance, if the cem be agitated in a solution of hydrochloric acid in water.

65. Fuller and Thompson found that cems, which failed to stand this test, failed also to set properly, while cems which passed it, also passed more elaborate chemical tests. (Trans A S C E, Vol 59, '07, Dec, pp 73–4.)

Properties and Tests of Cement. Report of Board U. S. A. Engineer Officers. Properties and tests of Portland, Natural and Puzzolan* cements. Digest of a Report of Majors W. L. Marshall and Smith S. Leach and Capt. Spencer Cosby, Board of Engineer Officers, on testing Hydraulic Cements. Professional Papers, No. 28, Corps of Engineers, U. S. A., 1901.

Unfortunately, tests for acceptance or rejection must be made on a product which has not reached its final stage. A cement, when incorporated in masonry, undergoes chemical changes for months, whereas it is seldom possible to continue tests for more than a few weeks at the most.

A few tests, carefully made, are more valuable than many, made with less care.

Cement which has been in **storage** for a long time should be **carefully tested** before use, in order to detect deterioration.

A cement should be rejected, without regard to the proportion of failures among samples tested, if the samples show dangerous variation in quality or lack of care in manufacture, and resulting lack of uniformity in the product.

The practice of offering a **bonus** for cement showing an abnormal strength is **objectionable,** as it leads to the production of cements with defects not easily detected.

For Portland or Puzzolan cement, make **tests** for (**1**) fineness of grinding; (**2**) specific gravity; (**3**) soundness, or constancy of volume in setting; (**4**) time of setting, and (**5**) tensile strength. For Natural cements omit tests (2) and (3).

(**1**) **Fineness.** Cementitious quality resides principally, if not wholly, in the very finely ground particles. Use a No 100 sieve, woven from brass wire No. 40 Stubs gage; sift until cement ceases to pass through. The percentage that has passed through is determined by weighing the residue on the sieve. The screen should be frequently examined to see that no wires have been displaced.

(**2**) **Specific gravity.** The specific gravity test is of value in determining whether a Portland cement is unadulterated. The higher the burning, short of vitrification, the better the cement and the higher the specific gravity If underburned, the specific gravity of Portland cement may fall below 3; if overburned, it may reach 3.5. Natural cement has a specific gravity of about 2.5 to 2.8, and Puzzolan about 2.7 to 2 8

The temperature may vary between 60° and 80° F. Any approved form of volumenometer or specific gravity bottle may be used, graduated to cubic centimeters with decimal subdivisions. Fill the instrument to zero of scale with benzine. Take 100 grams of sifted cement that has been previously dried by exposure on a metal plate for 20 minutes to a dry heat of 212° F., and allow it to pass slowly into the benzine, taking care that the powder does not stick to the sides of the graduated tube above the fluid, and that the funnel, through which it is introduced, does not touch the fluid. The approximate specific gravity will be represented by 100 divided by the displacement in cubic centimeters. The operation requires care.

(**3**) **Soundness,** and (**4**) **setting qualities.** The temperature should not vary more than 10° from 62° F. For Portland cement use 20, for Natural 30, and for Puzzolan 18 per cent. of water by weight. Mix thoroughly for 5 minutes. On glass plates make two cakes about 3 inches in diameter, ½ inch thick at the middle and drawn to thin edges, and cover them with a damp cloth. At the end of the minimum time specified for initial set, apply needle $\frac{1}{12}$ inch diameter, weighted to ¼ pound. If an indentation is made, the cement passes the requirement for initial setting. Otherwise the setting is too rapid. At the end of the maximum time specified for final set, apply the needle $\frac{1}{24}$ inch diameter, loaded to one pound. If no indentation is made, the cement passes the requirement for final set. Otherwise the setting is too slow.

Generally speaking, both periods of set are lengthened by increase of moisture, and shortened by increase of temperature.

---

* By **Portland** cement, in this report, is meant the product obtained by calcining intimate mixtures, either natural or artificial, of argillaceous and calcareous substances, up to incipient fusion. By **Natural** cement is meant one made by calcining natural rock at a heat below incipient fusion, and grinding the product to powder. By **Puzzolan** is meant the product obtained by grinding slag and slaked lime, without subsequent calcination.

Recommendations of Board of U. S. A. Engineer Officers. Continued.

In gaging Portland cement in damp weather, the samples should be thoroughly dried before adding water. This precaution is not deemed necessary with Natural cement. Sufficient uniformity of temperature will result if the testing room be comfortably warmed in winter, and if the specimens be kept out of the sun in a cool room in summer, and under a damp cloth until set. Temperatures may vary between 60° and 80° F., without affecting results more than the probable error in the observation.

Boiling test. Place the two cakes under a damp cloth for 24 hours. Place one of them, still attached to its plate, in water 28 days; immerse the other in water at about 70° F., and let it be in a rack above the bottom of the receptacle; heat the water gradually to the boiling point, maintain the heat for 6 hours and then let cool. The boiled cake should not warp or become detached from the plate, or show expansion cracks. If the cold-water cake shows evidences only of swelling, the cement may be used in ordinary work in air or fresh water for lean mixtures, but if distortion or expansion cracks appear in it, the cement should be rejected.

Accelerated tests are not generally recommended, but where a test must be made in a short time, the boiling test is considered about the best. It not only gives short-time indications, but at once directs attention to the presence of ingredients which might lead to disintegration. On the other hand, it may lead to the rejection of a cement which would behave satisfactorily in actual work and which would stand the test after air-slaking. Sulphate of lime, while enabling cements to pass the boiling tests, introduces an element of danger.

(5) **Tensile tests** are preferred to flexural or compressive tests. Sand tests are the more important and should always be made; and neat tests should be made if time permits.

A cement which tests moderately high at 7 days, and shows a substantial increase in strength in 28 days, is more likely to reach the maximum strength slowly and retain it indefinitely with a low modulus of elasticity, than a cement which tests abnormally high at 7 days with little or no increase at 28 days.

Use **briquettes** of the form recommended by the American Society of Civil Engineers,* measuring 1 inch square in cross-section at place of rupture, and held by close-fitting metal clips, without rubber or other yielding contacts. The tests should be made immediately after taking the briquettes from the water.

Neat tensile tests. Use unsifted cements. For Portland cement, use 20; for Natural, 30; and for Puzzolan, 18 per cent. water by weight. Place the cement on a smooth non-absorbent slab; in the middle make a crater sufficient to hold the water; add nearly all the water at once, the remainder as needed; mix thoroughly by turning with the trowel, and vigorously rub or work the cement for 5 minutes.

Place the briquette mold on a glass or slate slab. Fill the mold with consecutive layers of cement, each to be ¼ inch thick when rammed. Give each layer 30 taps with a soft brass or copper rammer weighing 1 pound, having a face ¾ inch diameter or 0.7 inch square, and falling about ½ inch.

After filling the mold and ramming the last layer, strike smooth with a trowel, tap mold lightly on side, to free cement from plate, remove the plate, and leave for 24 hours, covered with a damp cloth. Then remove the briquette from the mold and immerse it in fresh water, which should be renewed either continuously or twice in each week during the specified time.

Tensile tests with sand. For Portland and Puzzolan cements, use 1 part cement to 3 parts sand; for Natural or Rosendale, 1 to 1. Use crushed quartz sand, passing a No. 20 standard sieve, and being retained on a No. 30 standard sieve.

After weighing carefully, mix dry the cement and sand until the mixture is uniform, add the water as in neat mixtures, and mix for 5 minutes. The constituents should be well rubbed together.

For maximum strength in tested briquettes, Portland cements **require water** = 11 to 12½ per cent. by weight of constituent sand and cement; Natural, 15 to 17; and Puzzolan, 9 to 10.

A machine which applies the **stress** automatically and at a **uniform rate**

---

* See page 1236.

Recommendations of Board of U. S. A. Engineer Officers. Continued.

of increase is preferable to one controlled entirely by hand. The stress should be increased at the rate of about 400 lbs. per minute. A rate materially greater or less than this will give different results.

The highest tensile strength from each set of briquettes made at any one time is to be considered the governing test.

Field tests are recommended, whether or not the more elaborate tests above described have been made. In connection with tests of weight and fineness, and observations of texture and hardness in the work, field tests often suffice for well-known brands, showing whether the cement is genuine and whether it is reasonably sound and active. Pats and balls of neat cement from the storehouse, and of mortar from the mixing platform or machine, should be frequently made. Estimate roughly the setting and hardening qualities by pressure of the thumb-nail; hardness of set and strength by breaking with the hand and by dropping upon a hard surface. The boiling test may also be used. Should the simple tests give unsatisfactory results, then a full series of tests should be carefully made.

A cement may be rejected if it fails to meet any of the following requirements.

Requirements.

		Portland. Slow.	Portland. Quick.	Natural.	Puzzolan.
Fineness. Percentage to pass through a No. 100 sieve as in (1)		87 to 92*		80	97
Specific gravity. Between		3.10	3 10	Not	2.7
and		3 25	3.25	given	2.8

Engineering Standards Committee of Great Britain,

Adopted Nov. 23, 1904.

1. Consignments of from 100 to 250 tons to have expert testing and chemical analysis. For consignments of less than 100 tons, makers shall, if required, give certificate, for each delivery, that cem meets this spec'n.

2. Samples. Test samples to be taken as soon as bulked at factory or on the work, at consumer's option. Samples to be taken from each "parcel," each sample consisting of cem from at least 12 diff positions in same "heap," mixed together and spread out, 3 ins deep, for 24 hours, at a temp between 58° and 64° F.

---

* **Amendments** adopted by Am Soc for Testing Materials, Sep 1908·

Strength. The means of the values given shall be taken as the required minima where these are not specified.

Natural Cement. Omit specification for specific gravity.

Portland Cement. Specific gravity. For "thoroly dried at 100° C," read "ignited at a low red heat."

Loss of weight, on ignition, $\not>$ 4 %.

Requirements. Engineering Standards Committee of Great Britain. Continued.

3. Fineness.

Meshes per lin inch	Meshes per sq inch	Wire diam, ins	Residue not to exceed
76	5,776	0 0044	5.0 %
180	32,400	0.0018	22.5 %

Wire woven, not twilled.

4. Tensile strength.

Test room temperature, 58° to 64° F.

Water, fresh, renewed every 7 days. Temp 58° to 64° F.

Paste, smooth, easily worked, that will leave the trowel cleanly in a compact mass.

Briquette, filled, not rammed, into mold resting upon an iron plate, and left until cem has set. Briquette kept in damp atmosphere 24 hours; then in water until broken. Clips. See Fig. 1.

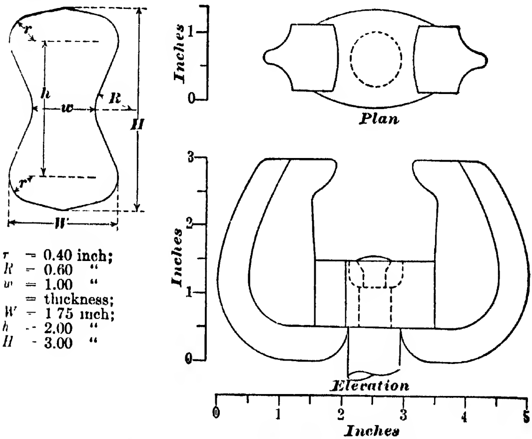

Fig 1. Briquet and Clips. British Standard.

Load, start at zero. Add 100 lbs each 12 seconds.

Neat test. 6 briquettes at 7 days, and 6 at 28 days. Av of the six accepted as the tensile strgth of the cement. 7 days, ≮ 400 lbs per sq. inch; 28 days, ≮ 500.

When 7 day test is betw	Increase, from 7 to 28 days, must be not less than
400 and 450 lbs per sq. in	25 per cent.
450 and 500 " " " "	20 "
500 and 550 " " " "	15 "
550 and over " " " "	10 "

Test with sand. By wt, 1 cem, 3 standard sand from Leighton Buzzard, thoroly washed and dried. Sand must pass No. 20 sieve of 0.0164 inch wire, and remain on No. 30 sieve of 0.0108 inch wire. Mixture thoroly wetted, but without superfluous water. 7 days, 120 lbs per sq inch; 28 days 225. Increase, from 7 to 28 days, not less than 20 %.

Requirements. Engineering Standards Committee of Great Britain. Continued.

5. Setting.	Time, mins maximum	minimum
Quick	30	10
Medium	120	30
Slow	300	120

"Set" has occurred when needle, loaded with 2½ lbs, with flat end 1/16 inch square, fails to make an impression.

6. Soundness. LeChatelier test. Expansion not to exceed 12 mm after 24 hours aeration; 6 mm after 7 days.

7. Specific gravity. Not less than 3.15, when sampled and hermetically sealed at makers'. Not less than 3.10, when sampled after delivery to consumer.

8. Analysis.
Water, ≯ 2 %, whether added or naturally absorbed from the air.
Calcium sulfate, ≯ 2 % of wt of cem, calculated as anhydrous calcium sulfate.
Lime, ≯ enough to saturate the silica and alumina.
Insoluble residue, ≯ 1.5 %. **Magnesia,** ≯ 3 %. **Sulfuric anhydride,** ≯ 2.5 %

Tests.

American Society of Civil Engineers.

Digest of report of Committee on Uniform Tests of Cement,* Jan '03, as amended Jan '04 and Jan '08.

1. Selection of samples left to discretion of engineer. Number of samples and quantity to be taken from each package depend upon importance of work, upon number of tests to be made and upon facilities for making them. Where conditions permit, sample one bbl in ten. Individual samples may be mixed, and av tested: but, where time permits, test separately.

2. Barreled cement to be sampled through a hole made in the center of a stave, midway between the heads, or in the head. Bagged cement to be sampled from surface to center.

3. Samples to be coarsely screened thru a No. 20 sieve.

4. Chemical analysis may show adulteration in the case of cems rich in inert material, but is not conclusive evidence of quality. Committee recommends method proposed by Committee on Uniformity &c , New York Section of the Society for Chemical Industry, see E N, '03, Jul 16, p 60; E R, '03, Jul 11, p 49.

5. Specific gravity test. Le Chatelier's method recommended. Fig 1. Flask, D, 120 cubic centimeters (cc); neck about 9 mm diam and 20 cm long, with bulb, C; vol, betw marks, F and E, 20 cc. Neck graduated, to 0.1 cc, above F. Neck of funnel, B, enters neck of flask, and extends to top of bulb, C. Use benzine (62° Baumé naphtha) or kerosene free from water. During the operation, in order to avoid variations in the temperature of this liquid, the flask is kept immersed in water, in a jar. Two methods, viz:

(a) Flask filled to lower mark, E. Weigh out 64 grams (2.25 oz) of the cem powder, cooled to temp of liquid. Thru the funnel, B, introduce the cem powder gradually until surf of liquid reaches the upper mark, F. Then 64 grams, minus wt of powder remaining unused, = wt, w, which has displaced 20 cc and

Specific gravity = w / 20.

(b) Fill, with liquid, to lower mark, E, as before. Add the entire 64 grams cem powder, liquid rising to some division of the graduated neck.

*Geo. S Webster, Richard L. Humphrey, Geo. F. Swain. Alfred Noble, Louis C. Sabin, Spencer B. Newberry, Clifford Richardson, F. H. Lewis, W. B. W. Howe. A S C E, Proceedings, Jan '03. Feb '04 Feb 08.

Tests. Am Soc Civ Engrs. Continued.

The reading of this division, plus 20 cc, is the vol, v, displaced by 64 grams of the powder; and

Specific gravity $= 64/v$.

6. Fineness. Sieves should be circular about 20 cm (7.87 ins) diam, 6 cm (2.36 ins) high, with pan 5 cm (1.97 ins) deep, and a cover.

Sieves should be of wire cloth,

No. 100, 96 to 100 meshes per lineal inch; wire 0.0045 inch diam.
No. 200, 188 to 200 " " " " " 0.0024 " "

Use 50 grams (1.76 oz) or 100 grams, cem; dried at 100° C (212° F). Hand sieving preferred. Use No. 200 sieve until one minute continuous sieving, at about 200 strokes per minute, passes not more than 0.1 %. Weigh residue, and treat it similarly on No. 100 sieve. A small quantity of large steel shot, placed in the sieve, expedites the work. The results should be reported to the nearest 0.1 %.

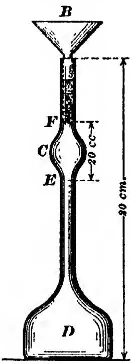

Fig 1.
Sp grav Flask.

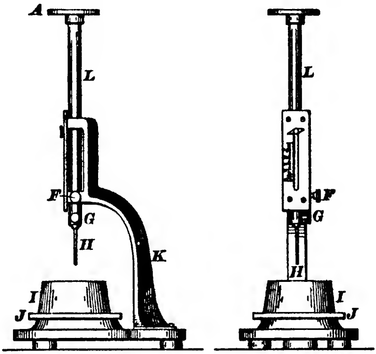

Fig 2.
Vicat Needle Apparatus.

7. Normal consistency. The percentage of water, used in making the pastes, for tests of strgth, soundness and setting, vitally affects the results. Normal consistency is determined as follows:

The quantity of cem, to be subsequently used for each batch in making the briquettes, but not less than 500 grams, is kneaded into a paste as under "Mixing," ¶ 12 quickly formed into a ball, with the hands, and tossed six times from hand to hand, held 6 ins apart. The ball is then pressed thru the larger opening of the Vicat needle apparatus into the gum ring, I, 7 cm (2.76 ins) diam, 4 cm (1.57 ins) deep, smoothed off below, and placed on the glass plate, J. Its upper surf is then smoothed off with a trowel. The point of the Vicat needle, H, is then brought into contact with the upper surf of the sample, and the cyl, L, is allowed to descend. The paste is of the normal consistency when the needle penetrates to a depth of 1 cm (0.39 in). With this rather wet paste, the committee believes that variations, in the amount of compression to which the briquette is subjected in molding, are likely to be less than with a drier paste.

8. Setting. Vicat needle, H, Fig 2, 1 mm (0.039 in) diam, loaded to 300 grams (10.58 oz). Setting has begun when needle ceases to pass a point 5 mm (0.20 in) above the upper surface of the glass plate; and has terminated when the needle does not visibly penetrate the mass. Test pieces kept damp, during test, by storage in a moist box or closet, or placed on a rack over water in a pan and covered by a damp cloth, the cloth resting upon a wire screen, so as not to touch the test pieces. Keep needle clean; as cem, adhering, seriously

Tests. Am Soc Civ Engrs. Continued.

vitiates results. Time of setting is materially affected by temp of mixing water, by temp and humidity of air, by the percentage of water used, and by the amount of molding paste receives.

9. Standard sand. Crushed quartz objectionable, "especially on account of its high percentage of voids, the difficulty of compacting in the molds, and its lack of uniformity." Comm recommends natural sand from Ottawa, Ill. Sand to pass a No. 20 sieve, with wire diam = half the diam of spaces betw wires; $\nless$ 99 % to be retained on a similar No. 30 sieve after 1 minute of continuous sifting of a 500 gram sample. The Sandusky Portland Cement Co., Sandusky, O., has agreed to furnish such a sand at actual cost of preparation.

10. Standard briquette. See Fig. 3. Am Soc Civ Engrs. Dotted lines are those recommended by earlier Comm. Trans, Vol 14, Nov. 1885.

	inch
r =	0.50
R =	0.75
R' =	1.75
h =	1.30
H =	3.00
W =	1.75
w =	1.00
	= thickness.

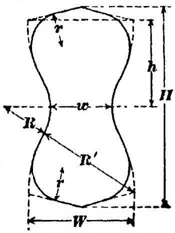

Fig 3. Briquet.

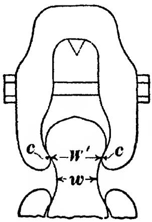

Fig 5. Clip.

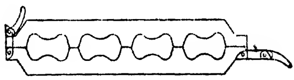
W' =	1.25 ins.
c =	0.25 "
	= contact with briquet.

Fig 4. Gang Mold.



11. Molds. "of brass, bronze or some equally non-corrodible material;" sides strong enough to resist spreading. Gang mold, Fig 4, recommended, because the greater quantity of mortar, required for it, conduces to uniformity of results. Molds to be "wiped with an oily cloth before using."

12. Mixing. Proportions stated by wt; quantity of water stated as percentage of dry material.

Metric system recommended.

Temp of room and mixing water as near 21° C (70° F) as practicable.

Sand and cem thoroly mixed dry. Mixing done on some non-absorbing surf, preferably plate glass. If an absorbing surf is used, it should first be thoroly dampened.

Quantity of material, mixed at one time, depends on number of test pieces to be made; about 1000 grams (35.28 oz.) convenient to mix, especially by hand methods.

Hand mixing and hand molding recommended. Material weighed, and placed on mixing table, and a crater formed in the center, into which the proper percentage of clean water is poured; material on outer edge turned into crater by aid of a trowel. As soon as the water is absorbed, the operation is completed by vigorously kneading with the hands for an additional 1½ minutes. A sand-glass affords a convenient guide for the time of kneading. The hands should be protected by gloves, preferably of rubber.

Molds filled immediately after the mixing is completed, material pressed in firmly with the fingers and smoothed off with a trowel, without mechanical ramming; material heaped up on the upper surface of the mold. In smoothing off, the trowel should be drawn over the mold, exerting a moderate pressure on the excess material. Mold turned over and operation repeated.

Tests. Am Soc Civ Engrs. Continued.

Weigh the briquettes "just prior to immersion, or upon removal from the moist closet," and reject those varying > 3 % from the av.

13. Moist Closet. "A moist closet consists of a soapstone or slate box, or a metal-lined wooden box—the metal lining being covered with felt and this felt kept wet. The bottom of the box is so constructed as to hold water, and the sides are provided with cleats for holding glass shelves on which to place the briquettes. Care should be taken to keep the air in the closet uniformly moist."

"Where a moist closet is not available, a cloth may be used and kept uniformly wet by immersing the ends in water. The cloth should be kept from direct contact with the test pieces by means of a wire screen or some similar arrangement."

14. Immersion. "After 24 hours in moist air the test pieces for longer periods of time should be immersed in water maintained as near 21° C (70° F) as practicable. they may be stored in tanks or pans, which should be of non-corrodible material"

15. Tensile strength. Solid metal clip, Fig 5, recommended. No cushioning between clip and briquette. Briquettes broken immediately after removal from water. Center the briquette carefully in the clip, to avoid transverse stresses. Load applied at rate of 600 lbs per min. "The average of the briquettes, of each sample tested, should be taken as the test" of that sample, "excluding any results which are manifestly faulty."

16. Soundness (Constancy of Volume). "In the present state of our knowledge it cannot be said that cement should necessarily be condemned simply for failure to pass the accelerated tests (below), nor can a cem be considered entirely satisfactory, simply because it has passed these tests."

Pats of cem paste of normal consistcy (¶ 7), abt 7.5 cm (2.95 ins) diam, 1.25 cm (0.49 in) thick at center, tapering to thin edge, made on a clean glass plate about 10 cm (3.94 ins) square, 24 hours in moist air before test.

(1) Normal test. One pat immersed in water maintained as near 21° C (70° F) as possible; one in air at ordinary temp. Both observed at intervals for 28 days.

(2) Accelerated test. A pat is exposed in any convenient way in an atmosphere of steam, above boiling water, in a loosely closed vessel, for 5 hours.

Pats must remain firm and hard, and show no signs of cracking, distortion or disintegration. Warping may be conveniently detected by applying a straight edge to the surf which was in contact with the plate.

Sand.*

Composition.

1. The sand,* used in mortar, is ordinarily made up chiefly of grains of **quartz (silica)**, with some impurities, mostly grains of silicious minerals. In testing cements. in the laboratory, crushed quartz or some standard natural sand is used. (See Spec'ns A S C E, under Cement, p. 1234.)

2. The silica of the quartz, in sand, undergoes **no chemical change** in the mortar; but the use of sand, by diminishing the quantity of cem reqd, reduces also the cost of the finished work. See remarks on strength, under Mortar, p 1248.

SIZES OF GRAINS.

3. Screening. Sand and gravel are screened, usually in an inclined fixed screen, upon which the material is placed by a conveyor, or shoveled by hand; or in an inclined revolving cylindrical or hexagonal screen, into which the material is fed.

4. Method of quartering. "To obtain an average sample from a pile of sand, gravel or stone, the method of quartering is useful. Shovelfuls of the material are taken from various parts of the pile, mixed together and spread in a circle. The circle is quartered, as one would quarter a pie, one of the quarters is shoveled away from the rest, thoroughly mixed, spread, and quartered as before. The operation is repeated until the quantity is reduced to that required for the sample." (T & T, p. 281.)

Mechanical Analysis.

5. The mechanical or granulometric analysis of sands, etc., is the determination, in any given sand or broken stone, of the proportions of grains of diff sizes. It is usually performed by means of sieves or screens. See ¶ 3. Sometimes, for broken stone, &c., by hand-picking.

6. Fig. 1 shows mechanical analyses of a gravel and a sand by Mr. Allen Hazen (Mass. State Board of Health, Report 1892, pp. 546–7). In order to represent both analyses on a single diagram, we have used diff scales for diams for the two materials.

7. In Fig. 1, the diagrams show, for the two materials there represented, that

of the sand, 10 % was in grains under, and 90 % over, 0.055 mm diam
" " gravel, 10 % " " " " " 90 % " 34.5 " "

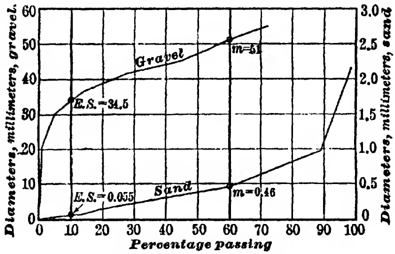


Fig 1. Sand Analyses.

***By "sand" or "gravel" we mean** a *mixture* of mineral particles with air, or water, or both; *i. e.*, an aggregation of mineral particles, with voids betw them said voids being filled with air, or with water, or with air and water, as the case may be.

Hence, the "volume" of a given quantity of sand or of gravel is the space occupied by both the solid particles and the air or water or both, filling the voids.

"Dry sand," or "dry gravel," means: not solid mineral, but a mixture of dry particles of sand (or gravel) and dry air.

The solid mineral portion of such sand or gravel, we designate as "solid."

Effective Size.

8. The effective size ("e. s.") of a sand or gravel, as defined by Mr. Hazen (Mass State Board of Health, Report 1892, p 341; Hazen, Filtration, pp 21, 240) is that size, than which 10 %, by wt, of the grains are smaller, and 90 % larger. Or, the length of the ordinate, at 10 % passing, gives the effective size. Thus, in the cases just mentioned, Fig 1, we have:

for the sand, e. s. = 0.055 mm; for the gravel, e. s. = 34.5 mm.

Uniformity Coefficient.

9. Uniformity coefficient. Similarly, let m = that diam of grain, than which 60 %, by wt, is smaller, while 40 % is larger. In Fig 1, we have

for the sand, m = 0.46 millimeters;
" " gravel, m = 51.00 "

The uniformity coefficient ("u. c."), is m/e. s.; and we have:

for the sand, u. c. = 0.46/ 0.055 = 8.4;
" " gravel, u. c. = 51.00/34.5 = 1.48.

10. With m = e. s., the unif coeff, u. c., would have its least possible value, = 1. In general the *less* nearly uniform a sand is, as to size, the *higher* is its "uniformity coeff."

11. In ordinary bank sand, the effective size, e. s., does not vary widely Hence the uniformity coefficient, u. c. = m/e. s., varies roughly with that diam, m, than which 60 % of the grains are smaller, and thus serves as an **indication of the coarseness,** as well as of the departure from uniformity, of the sand. (T & T, p. 182.)

Feret's Method.

12. Mr. R. Feret (Annales des Ponts et Chaussées, 1892, second semestre,) made elaborate experiments as to the effects of fineness of sand, and the mixture of different finenesses, upon the density, etc., of sand and upon different qualities of the mortar. He divided his sands into **three finenesses,** as follows.

Coarse,	c,	passing 5.0 mm diam	=	4 meshes / sq cm	=	5 meshes / lin in
Medium,	m,	" 2.0 " "	=	36 " / " "	=	15 " / "
Fine,	f,	" 0.5 " "	=	324 " / " "	=	46 " / "

"Coarse" grains are retained on 2.0 mm diameter; "medium" on 0.5 mm.

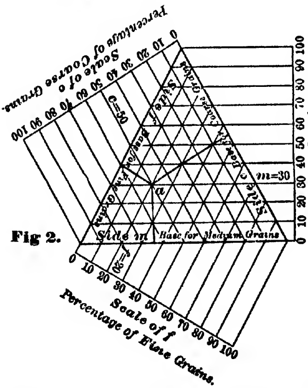

Fig 2.

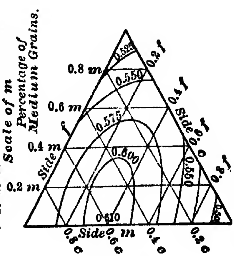

Fig 3.
Sand Analyses, Feret.
See ¶ 18.

13. The results, obtained in a certain case, with diff mixtures of these three grades of fineness, are shown in Fig 2, which is similar to diagrams used in connection with alloys of three metals.

14. After a given mixture has been analyzed, and its percentages of the three grades thus determined, it is plotted, in the triangle, by a point so placed that its perp dists, from the three sides, respectively, of the equilateral triangle, are as follows:

distance from side c = percentage of coarse grains;
" " " m = " " medium "
" " " f = " " fine "

15. The plotting of the points, and the measurements of their dists, are facilitated by the lines drawn parallel to the three sides respectively.

16. Thus, point a represents a sand having 20 % fine grains, 30 % medium and 50 % coarse, as shown by the three scales; 20, 30 and 50 being the dists of a from sides f, m and c, respectively.

17. When a series of experiments has been made, upon any given quality (as density or porosity, etc, etc) of sand or mortar, as affected by diffs in mixtures of the three finenesses, they are plotted in this way, and "contour" or **"iso"-lines** are drawn thru those points which represent equal results in the quality experimented upon. Each "iso"-line therefore represents a series of diff mixtures, each of which will give the value (as to density or porosity, etc, etc) represented by it.

18. Thus, in Fig 3 (T & T, p 144, Fig 51) the four contours and the point (0.610) represent five diff mixtures of coarse, fine and medium sands, said mixtures having densities (see ¶ 20) of 0.525, 0.550, 0.575, 0.600, 0.610, respectively.

Density.

19. Specific gravity or unit weight. Solid quartz weighs about 165 lbs per cu ft = 2.643 grams per cu cm; sp gr = 2.64 to 2.67.

20. In mechanics (see p. 338, Art. 14 a) **density is defined** as the *mass* in unit volume. In sand,* the solid portions have practically constant sp gr. Hence, for a given sand, "density" is used to designate the vol of solid in unit vol of sand, or the ratio of solid to total vol. This ratio is sometimes called the "absolute volume." Thus, in unit vol of sand, "density" = 1 — vol of voids.

21. The greater the density of sand,* the less cement will be reqd for a given quantity of mortar.

22. The weight, per cubic foot, of a sand,* of given sp gr. varies directly with its density; and this, in turn depends upon the shape of the grains, upon their *range* of size, upon the compacting accomplished, as by shaking, tamping, etc, and upon the dryness of the sand.

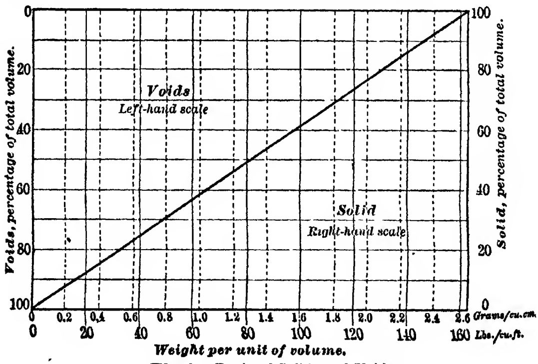

Fig 4. Ratio of Solids and Voids.

---

* See foot note*, p 1238.

23. Fig 4 shows the **relation** betw (1) the **unit weight** and (2) the **percentages of solid and of voids,** solid quartz weighing as in ¶ 19.

Effect of Moisture.

24. The effect of moisture, upon the vol of a given quantity of sand,* is affected by the vol of air introduced, by the quantity of water, and by the shape of the grains.
See ¶¶ 29 to 31.

25. It is impracticable to measure the vol of **air introduced,** and its presence vitiates all observations. When sand grains are dropped, one at a time, into water, most of the air, surrounding the grains, is left behind in the atmosphere; but when sand* is thrown into water in masses, or when moist or wet sand is turned over by shoveling, considerable and unknown quantities of air are entrained with it.

26. In moist sand,* the total (or "absolute") vol of voids is usually filled partly by water and partly by air.

27. Within a certain limit, **moisture** increases the adhesion betw the grains of sand, and thus opposes their sliding, one upon the other, consequently opposing the compacting of the sand; but, beyond that limit, it acts as a lubricant and facilitates the compacting. See ¶¶ 24, 25.

28. Let

V = volume, in cu ft, of dry quartz in 1 cu ft of sand;*
v = " " " " " voids " 1 " " " " ; $V + v = 1$ cu ft;
W = wt, in lbs, of 1 cu ft of pure solid quartz = 165;
w = " " " " 1 " " " the sand (dry or moist, as the case may be);
d = " " " " dry quartz in 1 cu ft of the sand; (in dry sand, $d = w$).
P = " " " " water added to 1 lb of dry sand;*
= " " " " " in $(1 + P)$ lbs of moist sand;
p = " " " " " " 1 lb " " " ;
m = " " " " " " 1 cu ft " " " .

Then $p/P = 1/(1 + P)$; and $p = P/(1 + P)$;
$m = w\,p$; $d = w - w\,p = w\,(1 - p)$;
$V = (w - w\,p)/W = d/165$; $v = 1 - V = 1 - d/165$;
$w = W\dfrac{1 - v}{1 - p} = W\dfrac{V}{1 - p}$.

29. The proportion, p, of moisture (lbs of water in 1 lb of moist sand), is ascertained by heating a known wt of the moist sand, at not less than 100° C (212° F), until no further loss of wt takes place, and noting the loss of wt. Then:
p = loss of weight ÷ original weight of portion heated.
In dry sand (Fig 4) $p = 0$, $w\,p = 0$, $w = d$; and we have:

$$V = w/W = w/165 = d/165.$$

Effects of Shape and Size.

30. Spherical grains. If a number of spheres, of uniform diam, D, be piled as closely as possible, the ratio of vol of solid to total vol is $\dfrac{\pi\sqrt{2}}{6}$ = about 0.74; and the voids (about 0.26 × the total vol) are of two sizes, such that they can be fitted, respectively, with spheres having diams = about 0.41 D and 0.22 D. (T & T, pp 169–170.)

31. Effect of gradation of sizes. The proportion of voids may be indefinitely reduced by adding to, and mixing with, the original grains, smaller and smaller, or larger and larger, particles, in proper proportions, each size occupying a portion of the voids left between the particles of the size next coarser. With spherical particles, therefore, the voids are greatest, and the wt per unit vol least, when the grains are of uniform size. This seems to hold true also for particles of other shapes.

---

* See foot-note*, p 1238.

Other Properties.

32. Turbidity test for silt in sand. *Separate the silt from a* considerable quantity of sand, and make up a special sample containing the max proportion of silt allowed by the spec'n. Place a small known portion of this mixture in a known quantity of clear water in a graduated vessel. Shake the vessel until the sample is thoroly washed. Insert a pin horizontally in the side of a stick near its end, insert that end of the stick into the vessel, lowering it until the pin is no longer visible thru the liquid, and note the depth of the pin by means of the graduation. Make several such tests and note the average depth of disappearance of pin. In testing samples, if the pin disappears at a higher elevation than the standard, the sand has more silt than the maximum allowable, and vice versa.* (W. J. Douglas, E N, '06/Dec/20, p 648.)

33. The presence of clay and loam, in sand, **may be detected** by rubbing the damp sand in the hand, and observing the condition of the hand, or by mixing the sand with clean water and noting the effect upon the water.

34. Washing. Dirty sand may be washed in a specially constructed sand washer; or, by means of a jet from a hose, in a box so arranged that the mud, clay and organic impurities are floated off, leaving the heavier sand behind.

35. Washing may carry off the finer particles of a well assorted sand, leaving it less dense than before. It is well to test a small quantity of the sand, washed and unwashed, before arranging to wash for use. (Jas. C. Hain, E R, '05/Jan/28, p 105.)

36. The degree of sharpness of a sand **may be estimated** by means of the sound emitted by it when kneaded betw the hands or more closely estimated by means of a magnifying glass.

MORTAR.*

Constituents.

1. Cement mortar consists of cem, mixt with water, with or without some inert granular material, as sand, fine gravel, stone or gravel screenings, or ground cinder. Without sand, etc., the mixture is called **neat** mortar, or **cement paste.**

Amount of Mortar Required for a Cubic Yard of Masonry.†

Description of Masonry.	Mortar. Cu yd. Min.	Max.
Ashlar, 18" courses and ¼" joints	0.03	0.04
" 12" " " "	0.06	0.08
Brickwork (bricks of standard size, 8¼ × 4 × 2¼ ins.):		
⅛" joints	0.10	0.15
⅜" to ¼" joints	0.25	0.35
⅝" to ½" joints	0.35	0.40
Rubble, of small, rough stones	0.33	0.40
" " large stones, rough hammer-dressed	0.20	0.30
Squared-stone masonry, 18" courses and ¾" joints	0.12	0.15
" " 12" " " "	0.20	0.25

2. Effect of roasting and of subsequent wetting. The materials, of which cem is made, are inert or stable compounds, remaining practically unchanged under ordinary conditions; but when, in burning, the calcareous materials are subjected to high temps, either alone or mixed with argillaceous materials, relatively unstable compounds are formed, ready to enter into new and again stable compounds when their particles are brought into intimate contact by being mixed with water, the water also entering into the new combinations. The mixture then soon "sets" (loses plasticity), and, shortly thereafter, begins to solidify and harden.
See ¶ 8, Cement, p 1223.

3. In the process of crystallization, the alumina appears to act chiefly as a **flux**, promoting the formation of the lime silicate, upon which the success of the operation depends. Iron oxide, which is generally present, seems to answer as well as alumina, as a flux, and it requires a less high temp for calcination.

4. The proportion of sand, which should be used in any given case, cannot be properly stated without stating also its range of size, or the proportion of voids to the whole mass; but, in general, good Portland cems will "carry" from 2 to 3 vols of sand; nat cems from 1.5 to 2 vols.

5. Approximate quantities of Portland cement and loose sand per cu yd of mortar.

	Neat	1:1	1:2	1:3	1:4	1:5	1:6
bbls cem	8.0	4.6	3.1	2.3	1.8	1.5	1.3
cu yds loose sand	0	0.65	0.87	0.97	1.02	1.06	1.10

Cement in Mortar.

See also CEMENT, p 1222.

6. Owing to the cheapness with which **cements** are now manufactured, and the superiority of the mortars made from them, the latter have to a great extent **superseded lime mortars,** even in ordinary building operations.

7. In selecting cem, a **reputation,** gained by years of successful use and experiment, is of greater value than the results of a few tests; but such **tests** are of value for excluding inferior parcels of such accepted brands.

8. High grade cements are usually economical, even at a higher cost, as they allow the use of a larger proportion of the cheaper ingredients, sand, gravel and broken stone.

---

*As the strgth, permeability, etc, of a conc depend largely upon those of its mortar, we discuss, under "mortar," many of its properties commonly discussed under "concrete"

† Taken, by permission, from "A Treatise on Masonry Construction," by Prof. Ira O. Baker. New York, John Wiley & Sons. 9th edition, 1907.

9. Free Lime. Cem may contain "free" (uncombined) lime as a result (1) of insufficient manipulation of the raw materials, (2) of insufficient burning, (3) of an excess of lime carbonate ($CaCO_3$) in the raw materials, or (4) of adulteration after burning and grinding.

10. This lime may be present either as quick lime, CaO, or as slacked lime $Ca(OH)_2$, either of which may be washed out (the CaO first becoming $Ca(OH)_2$) by infiltrating water. This, of course, weakens the cem.

11. Slacked lime takes no part in the hardening process, but remains as an inert filling material.

12. Quick lime slacks by absorption of the water used in mixing; and, when the burning has been at a high temp, the slacking is delayed. If it takes place during the setting of the cem, the swelling of the lime weakens the cem by rendering it porous. If slacking is delayed until after hardening, and if the expansive force is sufficient, the cem is disintegrated.

13. Excess of lime retards setting, and reduces soundness.

14. Free Magnesia. Much uncertainty exists as to the effect of free magnesia, in diff proportions, in cem. Like lime, it expands when wet, but much more slowly; and its presence may therefore remain unsuspected until too late. **Dolomite,** or magnesian limestone, contains about 45 % of magnesia. Formerly, 1.5 % of free magnesia, in cem, was considered dangerous. It is now generally believed that more than from 3 to 5 % weakens the cem, and that 8 % or more causes cracking. In any proportion, it is probably objectionable, at least as displacing an equal quantity of the more valuable lime.

Sand* in Mortar.

See also SAND, pp 1238, &c.

15. The quality of the concrete depends upon the strength of the mortar, and this, in turn, depends largely upon the character of the sand

16. For a given proportion by wt, the best sand is that which produces the smallest vol of plastic mortar.

17. Weight. As betw two sands, of a given material, the heavier of course has the smaller vol of voids.

18. Fineness. A fine sand, well assorted as to sizes of grain, and therefore dense, may make better mortar than a coarser sand, with grains of more nearly uniform size and therefore less dense.

19. Extreme fineness prevents penetration of the paste betw the grains, and delays setting.

20. Mortars made with fine sand, altho less permeable than those made with coarse sand, are apt to be more easily acted upon by **sea water.**

21. Shrinkage. Mortars, with coarse sand, shrink less than those with fine sand.

22. Sharpness. It has been customary to insist upon sharpness of grain, in sand used for mortar, probably owing to the impression that sharp grains form a better bond with the cem or that sharpness indicates freedom from impurities; but the advantage is doubtful. Sands with rounded grains are commonly used, and with entirely satisfactory results; and the laboratory tests generally indicate that sharp-grained sands have no marked superiority Roundness of grain facilitates the packing, and thus increases the density of the sand.

23. The Board of Public Works of Porto Rico, with briquettes of 1 : 2 mortar, found 25 % greater strgth with **washed** than with **unwashed** sand. Sand, containing much foreign matter, should be tested before being accepted.

24. In general, the evidence, as to the **relative values of sand and of screenings,** appears to be favorable to the use of screenings (see Experiments), but opinion is divided. The **hydraulicity of the dust,** in the screenings, may add to the strength of the mortar.

25. Harry Taylor, Capt, Corps of Engrs, U S A, tested 1650 briquettes of 1 : 3, 1 : 4 and 1 : 5 mortars, at 1, 3, 6 and 12 mos, with standard crushed quartz, Plum Island sand and **crusher dust.** Crusher dust gave briquets

* See foot-note, SAND, ¶ 1, p 1238.

2.3 times stronger than sand, and 72 % stronger than quartz. 1 : 5, with stone dust, stronger than 1 : 3 quartz.

26. G. J. Griesenauer, E N, '03/Apr/16, p 342. Chicago, Mil & St P RR, 225 tests, as follows:

Limestone screenings, 1 : 3, passing No 12, held on No 40 sieve, averaged 74 % better than Hammond pit sand, 1 : 3; with all sizes used, they averaged 115 % better. Mortar of 1 : 6 screenings was 23 % stronger than 1 : 3 sand. **Gravel screenings** were not much better than sand.

27. Maryland highways. Briquettes, made with **stone screenings,** were 34 to 62 % stronger than with Potomac River sand.

Lime in Mortar.

28. The substitution of 10 % to 20 % **lime paste** for an equal vol of cem paste, reduces the cost of the mortar, renders it less "short", and slightly retards setting, without seriously diminishing its strgth. Larger quantities reduce strgth. (Baker, Masonry Construction.)

29. Feret found the effect of lime dependent upon the richness of the cem mortar. With 1 : 4 cem mortar, the addition of 4 to 5 % of dry slaked lime increased the strgth; while, with 1 : 1.25 cem mortar, the addition of lime lowered the strgth. (Chimie Appliquée, 1897, p 481.)

Clay in Mortar.

30. Laboratory tests indicate that **a small admixture of clay** increases rather than diminishes the strgths of mortar, and diminishes its permeability; but, in actual work, the clay particles tend to adhere and thus to form lumps having but slight cohesion.

31. Laboratory conditions, as to dryness, pulverization, etc., cannot be reproduced in practice.

32. When the clay occurs naturally in the sand, it may not be practicable to effect a perfect mixture and distribution.

33. Clay, etc, are more likely to give trouble with dry than with wet mixtures.

Consistency.

34. Relative strengths of dry and wet mortars, 1 : 1. Alfred Noble. over 5000 experiments. Strength of dry mortar taken as 100.

	Portland cement				Natural cement			
Age	30 days	3 mos	6 mos	1 yr	30 days	3 mos	6 mos	1 yr
Dry Mortar....	100	100	100	100	100	100	100	100
Moderately stiff.	97	94	97	97	78	89	95	90
Grout.........	90	92	91	95	63	77	86	82

35. Use dry conc when it is to be heavily loaded at once. Tests indicate that wet and dry conc will be equal in strgth within a year.

36. Wet conc bonds better to old work than does dry conc. Excess of water increases efflorescence and laitance.

37. Rule for percentage, W, of water. H. P. Gillette, Cost Data, p 266.

Let S = parts of sand to 1 part cem. Then

$$W = (8\,S + 24) \div (S + 1).$$

This gives

when S =	1	1.5	2.0	2.5	3.0	3.5	4.0
W =	16	14.4	13.3	12.6	12.0	11.5	11.2

Falk finds that mortars, thus proportioned, adhere well to steel.

38. Slag cement requires plenty of water for its proper hardening. Therefore, if used in air, slag cem mortar should be kept damp.

Setting and Hardening.

39. Setting, or the loss of plasticity, usually occurs within a few hours (sometimes within a few minutes) after mixing cem with water; whereas **hardening** and **increase of strength** (which appear to result from a different set of chemical processes) often proceed for months or even years.

40. Molded blocks of Portland conc, of even 50 tons wt, can generally be handled and removed to their places in from 1 to 2 weeks

Initial and Final Set.

41. Initial and final set are stages of the setting process, arbitrarily distinguished by means of the resistance, of the mortar, to penetration by cylindrical wires, of standard diams and loaded with standard wts, the blunt ends of the wires resting upon the surf of a pat of the mortar formed in a flat cylindrical mold on a glass plate. See ¶ 8, p 1235.

Determination of Set.

42. Genl Totten, (Genl Q. A. Gillmore, Limes, Hydraulic Cements and Mortars, p 80,) at Fort Adams, R. I., prior to 1830, used a 1/12 inch wire, loaded with 0.25 lb, and a 1/24 inch wire, loaded with 1 lb; initial and final set being taken as the conditions when these wires, respectively, failed to make an impression upon the mortar.

43. Vicat used but one wire, or "needle." The A S C E (see specifications, p 943) prescribes, for this needle, a diam of 1 mm (0.039 inch) and a load of 300 grams (10.58 oz). Initial set occurs when the end of the needle, penetrating a pat of mortar 4 cm (1.57 ins) deep, can no longer approach within 5 mm (0.2 in) of the glass plate; and final set when the needle fails to sink visibly into the mortar. The mortar, under the setting test, must be of "**normal consistency,**" or such that a cylindrical rod, 1 cm (0.39 inch) in diam, loaded with 300 grams, its end resting upon the mortar, penetrates 1 cm into it.

Speed.

44. Speed. Some of the best cems are the slowest setting. A layer of very quick-setting cem may partially set, especially in warm weather, before the masonry is properly lowered and adjusted upon it, and **any disturbance, after setting** has commenced, is prejudicial. On the other hand, **quick-setting cements** are best in certain cases, as when exposed to running water, etc. They may be rendered slower by adding a bulk of lime paste equal to 5 or 15 % of the cement paste, without weakening them seriously. Nat cems usually set quickly. Slag cem sets slowly.

45. In general, **setting is accelerated** by high alumina and by soda and potash in the cem, by freshness and fineness of the cem, by the use of warm water and warm sand in mixing, and by warm weather. **Setting is retarded** by excess of lime and silica in the cem, by the presence of sand, by wetness of mixture, by cold, by retempering, by salt or sulfuric acid in the mixing water, by the presence of 1 or 2 % of lime sulfate, either hydrated (gypsum) or anhydrous (plaster of Paris) or of slaked lime, in some cases by hard burning, and in general, by the age of the cement, but the storage of new cem in warm places accelerates setting.

45 a. Gypsum. $CaSO_4$. Time of setting (initial and final) increased rapidly with additions of gypsum up to about 2 %, and remained constant, or increased slightly, up to 4 %. E. Candlot, "Ciments et Chaux Hydrauliques."

45 b. Time of setting (initial and final) increased, up to about 1.5 % gypsum, but then decreased, as the gypsum was increased to 7 %. Kniskern and Gass, Sibley Jour of Engng, '05, Jan.

45 c. Calcium chloride, $CaCl_2$. A *weak* solution *retards*, but a *concentrated* solution *accelerates*, the setting of Port cems. Thus, with 10 to 40 grammes per liter, the time of setting reached 500 to 850 mins; while, with 200 to 300 grammes per liter, it was reduced to from 2 to 25 mins. Cems with very high or very low alumina are but little affected by $CaCl_2$. A weak solution (30 to 60 grammes per liter) may render sound a cem containing free lime, by facilitating the hydration of the lime. E. Candlot, "Ciments et Chaux Hydrauliques."

45 d. From ½ to 1½ % dry $CaCl_2$, ground with cem clinker and made into pats of normal consistency (See Tests, ¶ 7, p 1235) increased the time of initial set from 2 to 167 mins, and that of final set from 52 to 275 mins. With 6 %, the times were 68 and 145 mins respectively, Kniskern and Gass, Sibley Jour of Engng, '05, Jan.

46. Setting is attended by an **increase of temperature.** In quick setting, this increase may amount to 10° C (18° F) or more.

47. Slow setting cems are apt to *harden* more rapidly than quick setting.

48. In warm air, setting cem, in drying, loses the moisture upon which the operation of hardening depends. It therefore **sets without hardening.** In hot weather every precaution should be taken against this.

49. Cems of the same class differ much in their **rapidity of hardening.** At the end of a month one may gain nearly one-half of what it will gain in a year, and another not more than one-sixth; yet at the end of a year both may have about the same strength. Hence, tests for 1 week or 1 month are by no means conclusive as to the final comparative merits of cements.

50. Many years are required to attain the greatest hardness; but after about a year the increase is usually very small and slow, especially with neat cem. Moreover, any subsequent increase is a matter of little importance, because generally by that time, and often much sooner, the work is completed and exposed to its max loads.

51. Cems which are slow-setting when made, are apt to **become quick-setting** (or "**flashing**") **when stored,** especially in warm places, and if the cem is underlimed. This is attributed to disintegration of the particles and consequent increase in fineness. The change sometimes takes place very quickly. This difficulty can usually be overcome, without reducing the strgth, by storage in cool places and by adding 1 to 2% of slaked lime. On small jobs, a few lumps of lime may be added to each bbl of mixing water.

52. The requirement, not uncommon in specfns, that a certain percentage of **increase of strength** must take place **between 7 and 28 days,** tempts the mfr to grind the cem coarsely, or to adulterate it with inert material, in order that it may not gain too much of its strgth within the first 7 days.

Properties.

Soundness.

53. Unsoundness, in cem mortar, is the tendency to expand, contract or disintegrate in air or water, or under heat and cold. See Specifications.

54. Cem, of any established brand, will seldom be found deficient in strength; but may be deficient in soundness, upon which durability depends.

55. Unsoundness is generally **due to** excess of free lime, arising from incorrect proportioning, overburning, lack of seasoning, or coarseness of grinding; the latter preventing perfect hydration. The presence of **lime sulphate** (gypsum plaster of Paris) is favorable to soundness. Unsound cem is improved by **storage.**

56. Change of dimensions during hardening of concrete. Conc, placed **in air, shortens** or shrinks during the first two or three months; while conc, **in water, expands** during about the same time. These changes are greater with those concs having the larger proportions of cem.

57. Shrinkage of mortar set **in air.**

	per cent.	ins. per 100 ft.
Neat cement,*........................	0.132 to 0.140	1.58 to 1.68
Mortar, 1 : 1,*........................	0.080 to 0.170	0.96 to 2.04
Lean mortars,†........................	0.030 to 0.050	0.36 to 0.60

The expansion **in water** is somewhat less than the contraction in air. The total change in dimensions is the algebraic sum of that due to setting, and that due to temperature changes.

58. Conc shrinks less when it sets **under pressure. Fineness of sand** is conducive to shrinkage.

Strength.

59. Cem mortars are usually tested (by means of briquets) for **tensile strength.**

60. Factors affecting strength. The strengths of samples, under test, are much affected by the temperature of the air and water, as also by the force with which the cem is pressed into the molds; by the extent of setting before being put into the water, and of drying when taken out; and still more by the pres under which it sets, which increases the strength materially. On this account, cems, in actual masonry, may, under ordinary circumstances, give better results than in tests of samples. The causes named, together with the degree of thoroness of the mixing, the proportion of water used, and other considerations, may easily affect the results 100 % or even much more. Hence the discrepancies in the reports of different experimenters. Specimens of the same cem, tested under apparently similar conditions, may give widely diff results.

61. Personal equation. In connection with the building of the Croton Aqueduct, New York, one set of testers, testing 835 briquets, obtained an av strgth of 62.3 lbs per sq in; while another set of testers, testing 2434 exactly similar briquets by the same methods and under the same circumstances, obtained an av strgth of 85.2 lbs per sq in, or 36 % greater.

62. Owing to such uncertainties, a series of tests, to be of value, **must cover a large number of specimens**, in order that the accidental diffs may be averaged.

63. Diffs in comparative results with diff materials may be due to one or other of several diffs betw the materials. Thus, in comparing mortars made with clean and with dirty sands, the strgths may be more affected by diffs in density than by the diffs in cleanness of the sand.

64. Effect of age. The diagram,* Fig 1, illustrates approx the strengths of av Portland and of av nat cems, neat and with 2 and 3 parts

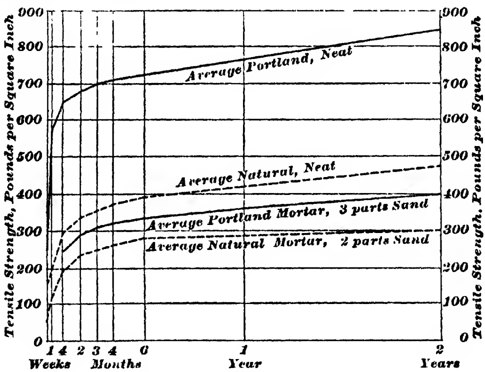

Fig 1. Age and Strength of Mortar.

of sand, up to an age of two years. Tests may readily vary 10 per cent or more eitherway from the average.

* See Richard L. Humphrey, in "Cement," Chicago, May, 1899.

65. Fig 2* shows, approximately, the effect of sand, in diff proportions, upon the strengths of Portland and natural cements, at diff

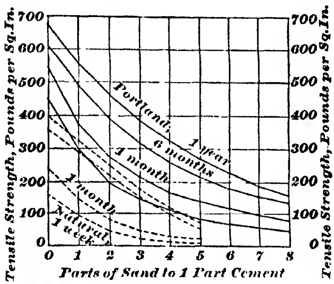

Fig 2. Effect of Sand upon Strength.

ages from 1 week to 1 year. The four solid curves represent average Portland cements, and the four dotted curves represent average natural cements For each kind of cement, the curves represent ages of 1 year, 6 months, 1 month and 1 week, respectively, beginning at the top. The curves for natural cement are carried only to 5 parts sand.

66. The compressive strengths of cem mortars, in cubes, appear to be about 8 to 10 times their tensile strengths, and their shearing strgths about ¼ their tensile strgths.

67. The adhesion of cem mortars to bricks or rough rubble, at diff ages, and whether neat or with sand, may be taken at an av of about ¾ the tensile strength of the mortar at the same age. If the bricks and stone are moist and entirely free from dust when laid, the adhesion is increased; whereas, if very dry and dusty, especially in hot weather, it may be reduced almost to nothing. The adhesion to very hard, smooth bricks, or to finely dressed or sawed masonry, is less than the adhesion to rough and porous surfs.

68. Dr. Bohme, Berlin, found tensile strgth ÷ adhesive strgth = '10, with 1 : 3 and 1 : 4 mortars, and = 6 to 8, with neat and 1 : 2 mortars.

Finish.

69. Lime mortar and cems, when used as mortar for brickwork, often disfigure it, especially near sea-coasts, and in damp climates by white **efflorescence,** which sometimes spreads over the entire exposed face of the work, and also injures the bricks. This occurs also, to some extent, with Portland cems; also in the mortar joints of stone masonry, but to a much less extent. It injures only porous stone. It is usually a hydrous soda or potash carbonate, or magnesia sulfate (Epsom salts) often with other salts. As a preventive, General Gillmore recommends to add to every 300 lbs (1 bbl) of the cem powder, 100 lbs of quicklime, and from 8 to 12 lbs of any cheap animal fat; the fat to be well incorporated with the quick-lime before slacking it, preparatory to adding it to the cem. This addition will retard the setting, and somewhat diminish the strength of the cem. It is said that linseed oil, at the rate of 2 gals to 300 lbs of dry cem, either with or without lime, will, in all exposures, prevent efflorescence; but, like the fat, it greatly retards setting, and weakens the cem. See also Bricks, p 1221.

70. For pointing, the best Portland cem should be used, and is best used neat, but it is often used with from 1 to 2 parts of sand. Mix under shelter, and in quantities of only 2 or 3 pints at a time, using very little water; so that the mortar, when ready for use, shall appear rather incoherent, and quite deficient in plasticity. The joints being previously scraped out

*Compiled, by permission, from Prof. Baker's "Masonry Construction."

to a depth of at least half an inch, the mortar is put in by trowel; a straight-edge being held just below the joint, if straight, as an auxiliary. The mortar is then to be well calked into the joint by a calking-iron and hammer, then more mortar is put in and calked, until the joint is full. It is then rubbed and polished under as great pressure as the mason can exert. If the joints are very fine, they should be enlarged by a stonecutter, to about ¼ inch, to receive the pointing. The wall should be well wet before the pointing is put in, and kept in such condition as neither to give water to, nor take it from, the mortar. In hot weather the pointing should be kept sheltered for some days from the sun, so as not to dry too quickly.

Behavior in Water.

71. Laitance. "When conc is deposited in water, especially in the sea, a pulpy gelatinous fluid exudes from the cem, and rises to the surface. This causes the water to assume a milky hue; hence the French term, *laitance*. As it sets very imperfectly, and, with some varieties of cems, scarcely at all, its interposition betw the layers of conc, even in moderate quantities, will have a tendency to lessen, more or less sensibly, the continuity and strgth of the mass. It is usually removed from the inclosed space by pumps, which must be used cautiously, to avoid disturbance of the conc by currents. The proportion of laitance is greatly diminished by reducing the area of conc exposed to the water, as by using *large* boxes, say from 1 to 1.5 cu yds capacity, for immersing the conc." (Gillmore, "Limes, Hyd. Cems & Mortars.")

72. Authorities differ as to the **effect of sea water.** H. LeChatelier (Internatl Assn for Testg Materials, Procs, 1906), finds that the active ingredients of cem (lime, aluminates, silicates) are decomposed by the magnesium salts of sea water, yielding soluble calcium chlorides and lime sulfates. The latter, with lime aluminate, forms a compound whose crystallization tends to swell and crack the material.

73. In view of the notable **puddling effect** of percolating water, it would appear that sea water especially, with its numerous salts, ought shortly to block its own passage into the conc.

74. The substitution of iron for alumina, in cem, is found to remove one of the most active reagents in the deteriorating effects of the salts in sea water.

See Cement, ¶ 30, p 1225.

75. The disintegration of conc in water (salt or fresh) appears to be due less to action of the water itself than to the repeated action of frost where the conc is alternately exposed to freezing temps between high and low water.

76. Mortar of puzzolano and lime has remained in perfect condition for 15 to 20 centuries in Italian harbor works.

77. At the dock at Kobe, Japan, to avoid possible injury, the salt water, inside the dam, was replaced with fresh water, which entered at the surface, while the heavier salt water was pumped out from the bottom.

CONCRETE.

For Cement, Sand and Mortar, see pages 1222, etc.

For abbreviations, symbols and references, see p 1251.

AGGREGATES.*

Constituents.

1. Order of value. (1) Trap, (2) granite, (3) gravel, (4) marble, (5) limestone, (6) slag, (7) sandstone, (8) slate, (9) shale, (10) cinders.

2. The strgth of conc, with good sandstone, is about 0.75 × strength with trap. With slate, less than half strength with trap. Good cinders nearly equal to slate and shale. Hardness of agg increases in importance with the age of the conc "because, as the cem becomes hard, there is greater tendency for the stones themselves to shear thru, and the hardness of the agg thus comes into play." (Sanford E. Thompson, E R, '06/Jan/27, p 109.)

3. The choice of agg is of course a matter of **cost,** as well as of strength, &c, of product. Thus, with gravel sufficiently cheap, as compared with broken stone, it may be economical to use the gravel, or a mix of gravel & stone, obtaining the reqd total stigth by using a larger mass of conc In foundations, on weak ground, this is advisable because it distributes the load over a greater area.

4. In many cases, the choice of sand and agg depends largely upon what material can be had, and upon its distance from the work.

5. Where cem is cheap, it may be economical to use materials nearest at hand, and to depend, for quality, upon excessive use of cem.

6. Stone which breaks into nearly cubical fragments packs better than that which splinters into long pieces, and the fragments are less apt to break in the finished work.

7. Good broken stone is usually preferred to gravel. The roughness of the stone particles is believed to give better adhesion. Gravel conc cannot well be tooled.

8. Cinders are sometimes used for the agg. They are ordinarily those resulting from the burning of **bituminous** coal under boilers. The material is mostly a fine ash, containing considerable unburned coal.

9. Anthracite cinders are less extensively used, the supply being less abundant.

10. Cinder conc. weighing only from 80 to 100 lbs per cu ft, is of advantage where **lightness** is reqd. Broken stone or gravel conc weighs from 140 to 145 lbs per cu ft.

11. Clay or loam, adhering to gravel particles, destroys or weakens the adhesion of the mortar to the stones. The Boston Transit Commission, Report for 1901, page 39, found the ratio of strength, betw conc with clean and dirty gravel, about 60 : 45.

See "Clay and Loam," under "Sand" and "Accidental ingredients," p 1135.

Size.

12. In beams, arches, &c, the **size of aggregate** should not exceed 1.5 to 2 ins on any edge; but, if it is well freed from dust by screening or washing, and if the mortar completely fills the voids, all sizes, from 0.5 to 4 ins. on any edge, may be used in mass work, as foundations, dams, piers, etc.

13. With large agg, coarse sand should be used, and vice versa.

14. It is usually economical of cem to **screen** sand from gravel or fine material from crusher stone, and then remix in the required proportions.

Density.

15. When a solid body is reduced to a mass consisting of broken pieces separated by voids, the increase in bulk is due solely to the **voids,** and is

---

* By "aggregate," we mean the solid materials of conc, other than the cem and sand. The term "aggregate" is sometimes used as including the sand also

equal to the space occupied by them. Hence the ratio, betw the **increase of bulk**, or "**swelling**," and the original bulk, is that of the voids to the *original*, and not to the final bulk. Thus, if a solid cu yd of stone, after being broken into pieces, occupies twice as much space as before, then the increase in bulk, or the space occupied by the voids, is = that occupied by solid pieces = half that occupied by the entire broken mass.

16. In sharp and angular broken stone, having all its pieces of nearly uniform size, about 50 **per cent** of the vol, when measured loose, will be **voids.** If the sizes of the stones vary betw somewhat wide limits, as from 2 ins down to ¼ inch, the vol, occupied by the voids, will be less, often as little as from 28 to 30 % of the whole.

17. Tests by Mr. Wm. M. Hall (Trans A S C E, Vol 42, 1899, p 132) of **voids** in crushed Green River blue limestone, 2.5 inch, screened; very clean Ohio River gravel, 1.5 inch, and mixtures of the two, resulted as follows:

Percentage of stone	100	80	70	60	50	0
" " gravel	0	20	30	40	50	100
" " voids	48	44	41	38½	36	35

These are avs of a number of tests of several bargeloads of materials, but there was little variation betw the mixtures.

18. Stone Crushers. See Price-list, p 1400.

Cyclopean Concrete.

19. "Cyclopean" conc, consisting of large, rough stones ("displacers" or "plums") laid in cem mortar, is largely, economically and advantageously used in mass work, especially in dams, where wt and hor shearing strgth are desiderata. The stones need not be flat. They are usually dropt into the wet mortar, without other bedding than that due to their fall and wt. Wet conc facilitates the bedding of the stones, and bonds better with them than does dry conc.

20. At Chaudiere water power dam, Canada, the "plums" were obtained from hard ledges in the river bed, in good shape for bedding. Their agg vol av'd betw 25 and 30 % of the vol of the dam; max, 40 %.

21. At Transmere Bay Development Works (Procs Inst C E, Vol 171, 1908, p. 145) the "plums" were of sandstone, 9 ins apart hor'y. Near the bases of the walls, they weighed a ton or more. The proportion of plums decreased, with wall thickness, from 10 to 7 % of the whole mass.

22. Unnecessary restrictions, imposed upon contractors, may eliminate the profit due to the use of "plums." See ¶ 19.

PLAIN CONCRETE.

1. Cement Concrete is composed of broken stone, gravel, cinders, slag, shells, or other hard and inert * material (the aggregate), held together by cement mortar, composed of cement and sand.

Advantages.

2. The principal advantages of conc are the convenience with which it may be placed, particularly in otherwise difficult situations or under water; its availability for subaqueous work; its cheapness, due largely to convenience of placing and to its use of stone too small for masonry; and its fire-resisting qualities, as compared with limestone (which calcines) and with granite (which splinters).

3. The availability of conc has been very greatly extended by the practice of **reinforcement,** which permits its use (heretofore often impracticable) in members subject to tension as well as to compression, as in beams, in cantilevers (including dams and retaining walls), in columns, and in arches where the rise is either very great or very small, relatively to the span. Reinforcement permits the use of much lighter sections than would have been safe when use was made only of the *compressive* strength of the material.

For reinforced concrete, see p 1278.

4. Disadvantages. Conc is rather weaker than good rubble masonry, and has only about half the strength of first class ashlar masonry of granite with thin joints in cem. Like both the stone and the mortar in masonry, it is subject to deterioration, especially in sea water; but this difficulty is being eliminated by the care which is being given to the manufacture of cem and which is fostered by its extensive use and by the conduct of its manufacture upon a large scale. As in all human work, and notably in the laying of masonry, care is necessary in order to secure faithful performance, upon which the success of the structure so intimately depends. The quality of the finished work may, however, be tested by borings.

5. Conc is used for **bringing up uneven foundations** to a level before starting the masonry. By this means the number of hor joints in the masonry is equalized, and unequal settlement is thereby prevented.

6. On railroad work, the use of conc may **obviate the use of derricks,** which are a source of interference with, and danger to, trains.

7. Conc is used to advantage in reinforcing and **protecting old stone masonry;** but, unless special precautions are taken, the two constructions are liable, in time, to separate, owing to unequal settlement, especially if the ramming has not been thoro.

Natural Cement.

8. Natural cement is now seldom used in conc, except in mass work where it is not subjected to the wearing action of water or frost, and where early strength is not reqd. It is suitable for footings and for low retaining walls not subject to serious vibration.

9. In dams, breakwaters, etc, the **core** is frequently *of natural cement* conc; with a substantial outer shell of Portland cem conc.

Proportions.

10. The proportions of cement, sand and aggregate should theoretically be **determined,** either all by wt, or all by measure in loose condition; but, in practice, the cem is measured by the number of packages used (the contents of the packages being known; see "packages," under "Cement") and the sand and agg are measured loose.

---

* Without chemical affinity for other materials.

"Natural Mix."

11. It is customary to designate the quantities of cem, sand and agg, in a conc, by proportions. Thus: 1 : 2 : 4 means 1 part cement to 2 parts sand and 4 parts aggregate. Such designation is necessary in instructions to workmen; and, where the ranges of size of the particles are known, it indicates the character of the conc. The proportions are of course governed by the character of the work; but it is inadvisable to affect distinctions between nearly similar classes of work.

12. Usual proportions for Portland cement concrete:

Exceptionally massive work (leveling for foundations, dams, breakwaters) 1 : 1.5 : 8 to 1 : 5 : 10; with nat cem, 1 : 2 : 5.

Foundations, ordinarily, 1 : 3 : 6; sometimes as poor as 1 : 4 : 8.

Piers, pedestals, abutments, 1 : 2.5 : 5.5 to 1 : 3.5 : 7.

Piers and vaulting in filters, 1 : 2.5 : 5.5.

Reinforced walls and beams, 1 : 3 : 6; light sections, 1 : 2.5 : 5.

Foundation walls, 1 : 2.5 : 5.5; retaining walls, 1 : 2.5 : 5.5 to 1 : 3 : 6.

Spandrel walls, 1 : 3 : 6.

Conduits, drains, sewers, 1 : 2.5 : 5.5 to 1 : 3 : 6.

Reservoir, filter and tank walls, 1 : 1.5 : 3.5 to 1 : 2.5 : 5.5.

Subaqueous work, 1 : 2 : 3.

Floor systems (girders, beams, slabs) 1 : 2 : 4 to 1 : 2.5 : 5.5

Stairways and roofs, 1 : 2 : 4.

Arches, 1 : 2.5 : 5; light sections, 1 : 2 : 4.

Copings and bridge seats, 1 : 1 : 2 to 1 : 2 : 4.

But the essential requisite is that all the voids, between the particles of sand and agg, be filled with cem mortar. Hence, unless the grading of sizes, of sand and of agg, is known or assumed, the bare statement of proportions, of cem, sand and agg, in a mixture, gives but little useful information as to the value of the conc.

13. In reinforced work, in general, richer mixtures should be used than those that would be permissible in large mass work. In order to obtain proper and reliable adhesion, which is of the first importance, the bars must be completely surrounded by cem.

Materials Required.

14. Materials required for a cu yd of rammed Portland cement concrete. c = cement, bbls; s = sand, cu yds; a = aggregate, cu yds. Dust screened out. Stones not larger than 1 inch.

Mixture	c	s	a
1 : 2 : 4	1.46	0.44	0.89
1 : 2 : 5.5	1.19	0.46	0.91
1 : 3 : 5	1.11	0.51	0.85
1 : 3 : 6	1.01	0.46	0.92
1 : 3 : 7	0.91	0.42	0.97
1 : 4 : 7	0.83	0.51	0.89
1 : 4 : 8	0.77	0.47	0.93

With 2.5 inch stone, the quantities of all the materials, per cu yd conc were increased from 2 to 5 %. With gravel, $\not>$ ¾ inch, they were decreased about 9 %. (Chas. A. Matcham, Natl Builders' Supply Assn, 1905.)

15. Let

B = No. of barrels of cement reqd per cu yd conc
= No. of times 0.141 cu yd cement reqd per cu yd conc;
P = parts of sand (or agg) to 1 part cem.

Then

$1/B$ = No. of cu yds conc from 1 bbl cem;
$0.141\ P$ = No. of cu yds sand (or agg) to 1 bbl cem;
$0.141\ PB$ = No. of cu yds sand (or agg) to 1 cu yd conc

Voids. *See Weight, p 1271.*

16. Reduction of voids. *If stone having 50 % voids, and sand having 50 % voids, be used, with cem, in the proportions:*

Cement, 1 part = 0.25 cu yd
Sand, 2 parts = 0.50 cu yd
Stone, 4 parts = 1.00 cu yd

the resulting conc will measure something more than 1 cu yd, and yet it will contain unfilled voids.

17. These proportions, however, are not economical By selecting a sand having a **range of size,** or by mixing two or more sands having grains of diff sizes, the voids in the sand can be reduced to say 33 %. Similarly, the voids in the stone can be reduced to say 35 %. We should then have, say:

Cement, 1 part = 0.12 cu yd
Sand, 3 parts = 0.36 cu yd
Stone, 8 parts = 1.00 cu yd,

with results as good as with the 1 : 2 : 4 mixture above, although using only half as much cement.

18. Mr. Geo. W. Rafter (Trans A S C E, Dec, 1899, Vol 42, p 106) recommends that the proportions be stated by means of the ratio of the vol of the mortar to the vol of agg. Thus: a conc containing 75 vols of agg and 25 vols of mortar, would be a 33⅓ % conc.

19. Under usual conditions, the **voids** in the agg **should be filled** with as rich a mortar as the strength of the work demands. A better conc may result from the use of a lean mortar which fills the voids, than with a richer mortar but partially filling the voids.

20. The mortar cannot be perfectly distributed thru the agg, and some of the voids are too small to admit the sand grains. Moreover, the mixture is liable to disturbance in depositing. Hence, there will be voids in the conc unless there is an excess of mortar over the measured voids of the agg.

21. In practice, the **excess of volume of mortar required,** over the measured voids in the agg, in order to secure the filling of the voids, is usually from 15 to 25 % of the vol of the voids. But by 15 exp'ts with limestone, Prof. Baker found that the voids were not entirely filled unless the vol of the mortar exceeded the vol of the voids by 40 %. (Table 13 c, p 112 b, Baker's Masonry Construction, 1907.)

22. Mr. John Watt Sandeman (Procs, Instn C E, Vol 121, p 219, 1895) believes that, **to insure watertightness,** the vol of mortar should be 50 % of the vol of agg having 35 % voids; or, excess mortar = 43 % vol of voids.

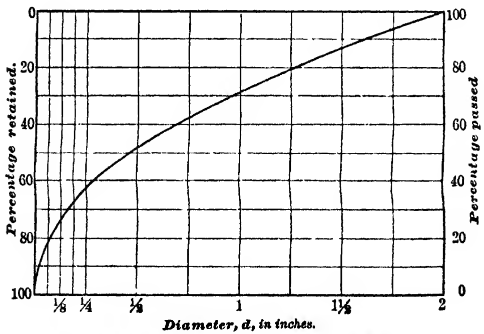

Fig 1. Parabola of Maximum Density. See ¶ 23, p 1257.

Density. See Weight, p 1271.

23. Mr. Wm. B. Fuller (T & T, p 197) finds that the **greatest density** is obtained, and consequently the smallest amount of cem reqd, when the agg and the sand are so graded that the percentages, by wt, passing the various sieves, are as represented by the ordinates of the parabola in Fig. 1, where the abscissas represent the diams, *d*, of the openings in the sieves while the ordinates *below* the parabola represent the percentages *passed*, and those *above* the parabola the percentages *retained*, by these openings respectively.

24. In this parabola $d = P^2 M$; where d = a given diam; P = proportion of particles smaller than d; M = max diam of stone (= 2 ins in the Fig).

25. Exp's (Trans A S C E, Vol 59, pp 67, &c, 1907) show that a saving of 12 % in quantity of cem may be effected, and a more impervious product obtained, by thus grading the sizes of the sand and agg; but the reduction may sometimes be offset by the additional cost of so grading, especially on small work.

26. In the lining of the tunnel for the Sudbury aqueduct, Boston Water Works, the proportions were

1 cask of Portland cem as it came from the dealer	=	3.425 cu ft
2⅙ casks of loose sand	=	7.35 cu ft
5½ casks of loose crushed stone	=	18.56 cu ft
Total		29.335 cu ft.

By slightly shaking the sand and stone, the proportions became practically 1 : 2 : 5.

These 29.335 cu ft produced from 20 to 21 cu ft conc, rammed in place: or say 38 cu ft materials = 1 cu yd conc

27. Mr. Wm. B. Fuller (Natl Assn of Cem Users, Procs, '07, p 95) tested conc beams, 30 days old, of 1 : 2 : 6, 1 : 3 : 5, 1 : 4 : 4, 1 : 5 : 3, 1 : 6 : 2 1 : 8 : 0, (all 1 : 8). The strgths compared as in Fig 2.

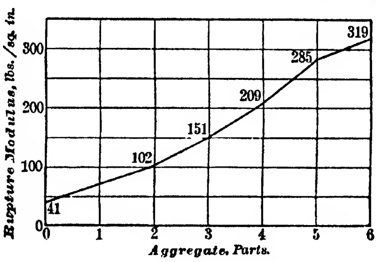

Fig 2. Proportions; strength.

28. From this it appears that, so long as the voids in the agg are filled with mortar, the comp strength of conc seems rather to increase than diminish as the proportion of stone increases, and to depend largely upon the richness of the mortar.

29. Proportioning by trial mixtures: (Wm. B. Fuller, Trans A S C E, Vol 59, pp 77, &c).

Having determined the particular sand and stone to be used on any work, provide a strong and rigid cylinder, such as a short piece of 10 inch wrought iron water pipe capped at one end.

30. On a piece of sheet steel or other non-absorbent material, weigh out and mix together all the ingredients, to the consistency required for the work. Place the mixture in the cylinder, tamping carefully and continu-

ously, and note the height to which the cyl is filled. Before the mixture has time to set, empty and clean the cyl

31. Make up another batch, using the same wts of cem and of water as before, and the same *total weight* of sand and stone, but with a slightly *diff ratio of weights* of the sand and stone.

32. Note the height, in the cyl, reached by this second and by subsequent mixtures The best mixture is that *which gives the least height in the cyl*, provided that it works well while mixing, and that its appearance in the cyl shows that all the stones are covered with mortar.

33. This method enables the engineer to select the best from the materials available in any given case.

Consistency. See also Mortar, p 1245.

34. Skill and care, in placing, and *uniformity* of consistency are more mportant than the consistency itself.

35. The extremes of **practice** are: (1) Conc with mortar about as moist as damp earth; only enough water used to show on the top surf after prolonged and hard tamping, (2) enough water used to cause the conc to quake when first placed, and to allow only of spading into place. The proper consistency depends largely upon the character and purpose of the work.

36. Dry conc is generally preferable in large open work where it can be thoroly rammed, and where early strength is reqd, as in arch skew-backs. When thoroly tamped, it develops much higher compressive strength at its early ages, and may have somewhat greater permanent strength, than wetter mixtures; but imperfect tamping of such mixtures may result in very weak conc, while thorough tamping may render the work more expensive than the increased strength will justify.

37. Medium. Present practice favors the use, in general, of mixtures wet enough to require only spading; but, even in such work, ramming may be reqd from time to time for occasional dry batches.

38. Wet conc is more easily mixt with thoroness, more readily and more cheaply laid, and more easily forced into the narrow spaces betw reinforcing bars. It comes into more perfect contact with the molds, thus giving smoother and more nearly watertight surf. It is therefore generally preferable (as in buildings) in forms of complicated shape, or in thin sections, or where smooth surfaces are reqd.

39. Wetness retards setting, gives better bond between successive courses, gives a compact mass with less tamping, and provides the surplus water reqd by absorption in wooden forms. Wet conc is less liable than dry to injury by bad workmanship; but an excess of water reduces the strgth, and increases efflorescence.

40. In "cyclopean" conc, more "plums" can be used with wet conc, which allows them to settle down into it, and which bonds better with them.

41. Mixtures, **wet enough to be poured** into the forms for columns of floors, are frequently used.

42. The quantity of water required, for a given consistency, is materially reduced by wet weather.

43. Water works upward thru placed conc. Hence a less proportion of mixing water may suffice toward the end of a day's work.

HANDLING AND MIXING.

Handling Ingredients.

1. In designing a plant for **handling and mixing** conc, the quantities to be handled, the areas over which they must be distributed, the facilities for procuring and receiving the raw materials, and the working space available, must be considered; and each case will present other factors, peculiar to itself,

2. The **arrangements** of such a plant are as various in character as are the different kinds of work. In general, these arrangements must be specially designed for each important work; and success and economy depend largely upon the excellence of the design of the handling plant.

3. Materials may reach the site by cars, boat or team. Be on guard against mud and dirt in bottom of vehicle. Sand and agg may be dredged from stream at the site.

4. After reaching the work, the materials are carried to the bins, by carts, barrows, small cars, dredge buckets, or belt or chain conveyors. From the bins they are usually carried by gravity, thru hoppers, to the mixer.

5. Storing. Cem is commonly stored in sheds or other warehouses, and is handled, separately from sand and agg, in bags or bbls, often by means of chain conveyors.

6. For bringing the materials from the **bins to the mixers,** and the conc from the mixers to the work, carts, barrows or small cars are used.

7. Where the work covers a limited hor area, as in the case of a building, or of a pier or abut, **the mixer** need not be frequently moved, and the arrangements for handling are relatively simple.

8. Where the work covers a large hor area, as in a slow filtration plant, or where it crosses a valley, as in a dam; cable conveyors, with towers, are used; or one or more mixing plants are installed in central positions.

9. Where the work extends along a line of considerable length, as in walls, sewers or aqueducts, a railway track, often of broad gage and with three or more lines of rails, is laid alongside, and the materials handled from derrick cars, often of designs specially prepared for the work in hand.

10. The work is facilitated by having the cars, barrows, buckets, etc, of known capacity, so that they may serve as measures in proportioning the sand and agg. Thus, the cars may hold enough sand or agg for one batch, and may dump into larger boxes, each holding enough sand and agg for one batch. The cem is usually measured separately, by counting the bags or bbls emptied.

11. Where **cars** are used, they may be moved by locomotive or by cable, reaching the bins by means of an inclined plane.

12. In the case of a **belt conveyor,** sand and stone, each enough for a batch or other known quantity of conc, and afterward the cem for the same quantity, are dropped upon the belt from their respective bins.

13. Commonly the **measuring platform** (or the measuring hopper for batch machines) is placed directly over the mixer.

14. For max output, there should be two sets of measuring hoppers, one to be dumping into the mixer while the other is filling.

For washing sand, see SAND, ¶ 34, p 1242.

15. Agg may be washed in a revolving cylindrical screen, by a jet of water under high pressure.

16. Work is often done **at night** by means of electric or other artificial illumination.

17. Portable (flat-car) conc mixing plant. Two 6 × 8 timbers, 58 ft long, 4 ft apart, laid upon floor of a 34 ft standard-gage flat car, their ends projecting 12 ft beyond each end of car, and guyed to an elevated framework on center of car. Each projecting end carried a 2 cu yd hopper. Sand and gravel were shoveled into this hopper and discharged from it upon a belt conveyor, running hor'y under the hopper and then upward to a hopper (3 cu yds) 15 ft above the car floor, over the center of the car. This elevated hopper discharged the sand and gravel into a ¾ cu yd Smith mixer, placed at the center of the car. Cem supplied to the mixer by hand; water from a pipe, laid along the work and provided with hose connections. A bbl, filled with water, was carried on the elevated framework, to ensure a supply for immediate use. The conveyor belt, 2 ft wide, consisted of two link-belt chains, with a heavy double-thickness canvas belt between them. Belt supported by wrought-iron pipe cross-pieces 18 ins apart. The belt forms pockets between the cross-pieces. Conveyors, driven by a 9 × 16 inch single-cylinder steam engine, mounted on one end of the car. Average capacity, 275 cu yds per day. One lower hopper was found sufficient to supply the mixer. (The Chalmette Docks of the New Orleans Terminal Co, E. R, '06/Jul/28, p 90.)

18. In constructing works which are circular in plan, the mixt conc for floors, columns, girders and roof, may be carried to the forms by means of a truss bridge, spanning the work from a central tower to a track on the

circumferential wall. The bridge then forms a **revolving crane,** carrying mixers at its outer end.

Mixing.

19. General. Each sand grain should be coated with cem, and the mortar should coat every fragment of stone in the agg and should be evenly distributed thru the whole vol. The stone, if dry, should be wetted before adding it to the mortar.

20. Thoroness of mixing is of the greatest importance; especially when the conc is poor in cem or of dry consistency.

21. The great strgth of the conc in the Munderkingen bridge is attributed to its thoro mixing. The materials were mixt 2 mins dry and 3 mins wet.

22. Variation in **color** of mixture indicates change in the proportions of the ingredients.

23. See that any cem, thrown out as defective, is replaced by good cem.

24. Lifting concrete. Where the mixing platform cannot be built near the level of the top of the structure, the conc may be raised by a power lift to the proper level, and then wheeled on level runways. For low lifts and small quantities, horsepower lifts are used; for higher lifts and larger quantities, a small steam or gasoline engine.

25. In some cases, the mixer and its enclosing frame are lifted bodily by the derrick which supplies materials, and deposits them over or near the work.

26. Hand mixing is inadvisable and uneconomical, except on small jobs.

27. In hand mixing, it is usual to mix the sand and cem dry, usually by turning with shovels two or three times, until the mixture is of uniform color, and each sand grain is coated with cem.

28. Water is then added, and the mortar is mixed before the agg is added; or the agg may be spread over the dry mixed sand and cem, or these thrown upon the agg, and the whole then wet and mixed by two or more turnings with shovels, until the water is thoroly incorporated.

29. Mixing the cem and sand first, as above, reduces the total labor by omitting unnecessary manipulation of the agg.

30. Weather. Hand mixing should be well protected against wind and rain. Wind blows away the finest (and therefore best) of the cem, and rain prevents proper (dry) mixing of cem and sand.

31. For the sub-station of the Brooklyn Rapid Transit Co., two bottomless rectangular frames were provided, one of which had a capacity of ½ cu yd, and was first filled with sand. Seven bags of cement were then emptied on top of it, and the mass was turned several times by five shovelers until the color was uniform. It was then leveled, the other frame (1 cu yd capacity) was placed on top and filled with broken stone, and water was put on with a hose. The mass was then turned four times, shoveled into wheelbarrows and deposited in the forms.

32. With equal care, **machine mixing** gives better and more reliable results than hand mixing, and is more economical on large work.

33. The **output must be carefully watched,** as the accidental and unsuspected choking of a hopper may change its character.

Mixers.

34. Mixers are of **two principal types;** "continuous," and "batch."

35. In **continuous mixers,** the raw materials are fed continuously into the machine at one end, and the mixed conc is delivered continuously from the other end.

36. The gravity (continuous) mixer is a stationary shute or trough, set nearly vert, and equipped with fixed projecting pins or baffles, against which the material impinges as it descends, and upon which the mixing depends. Water is admitted by a spray pipe, at the top of the shute. Power is required only to elevate the materials to the top of the mixer, usually a lift of about 8 feet.

37. Other continuous mixers are in the form of open troughs, nearly hor, and having a longitudinal revolving shaft, with screw-like blades

attached, which convey the material, fed in at the upper end, thru the length of the trough, to the lower or discharging end. Water is provided by means of perforated pipes along the sides of the trough.

38. **Measuring.** Continuous mixers require some means of proportioning the ingredients of the conc. Various automatic measurers have been used to a limited extent. Sometimes the sand, cem and agg are spread, in layers, on the platform of the mixer, and shoveled into the mixer. Sometimes, dependence is placed upon assigning, for instance, one shoveler for the cem, three for the sand and six for the stone; but this method is much too crude for most cases.

39. **Batch mixers** deliver the conc in batches, the size of which is determined by the capacity of the mixer. They have a wider range than gravity mixers, and give better control of the proportioning of the ingredients.

40. The oldest and simplest batch mixer consists of a revolving **cubical** iron box, plain inside, mounted on bearings at its diagonally opposite corners, and provided, on one side, with a sliding gate, for admitting the raw materials and discharging the conc. Power is applied thru gearing on the shaft. The ingredients may be mixed dry for a number of turns, and the water then added thru the hollow trunnions; or the water may be added before any mixing is done. The older cubical mixers had to be stopped, both at the time of charging and when delivering the conc.

41. At Superior Entry, Wis., the U. S. Govt used a cubical conc mixer, charging and discharging without stopping and without variation of speed. It was operated by a 7 × 10 inch vertical single steam engine, and turned out a batch of very perfectly mixt conc in 80 secs. The conc was plainly visible during the entire process. (Clarence Coleman, Rept of Chf of Engrs, U. S. A., 1904, Part IV, p 3784.)

42. In later batch mixers the cubical box is replaced by a **drum** (either cylindrical or made up of two cones), rotated by means of a chain on a ring encircling the drum, and provided with vanes or blades fixed upon the inside. These blades first carry up and then drop the material, mixing it by the agitation so caused. The discharge is effected, in the Smith (double cone) machine, by tilting the machine (like a Bessemer steel converter) about its trunions, placed at cen of grav of drum; and, in the Ransome (cylindrical drum) machine, by inserting a tilting trough, which, in the discharging position, catches the material as it falls from the blades.

43. To provide against **break-downs, extra parts** should always be furnished with each mixer.

44. **Mounting.** Mixers are either stationary, or mounted on skids or wheeled trucks, with or without steam engine, engine and boiler, gasoline engine or electric motor.

45. The mixer, with its framing, is sometimes lifted bodily from its old location, and deposited in a new one, by a derrick or cableway.

46. **Wheeled conc mixers,** with revolving drums, into which the ingredients are loaded, and in which they are mixt by means of the forwd movemt of the vehicle, have been used. The motive force may be given by hand, by horse-power or by gasoline engine; and the relation, betw forward speed and speed of rotation, may be regulated by gearing.

47. Small **hand-power** batch mixers are furnished; capacity claimed > 450 cu ft per day.

48. In the **choice of a mixer,** reliability, as established by successful use, is of prime importance, especially where continuity of work is essential.

49. Shortage of output may be due to **shortage of power** behind the mixer, as well as to the mixer itself.

50. The mixer **should be cleaned** after each day's work.

PLACING.

51. The best conc may be rendered almost worthless by carelessness or improper method in the placing.

52. When conc is **dumpt from a considerable height,** there would seem to be danger that the even distribution of materials may be disturbed. Hence, if lowered in buckets, these should be brought close to the work already done, before dumping. However, in the construction of

conc piers for a bridge at Bethlehem, Pa., by Cramp & Co. (E R, '09/Mar/6, p 280) conc was delivered, thru an inclined wooden shute, lined with sheet iron, at a point vert'y 74 ft below the mixer; and the method was found to be economical, and the conc uniformly good, and there was no difficulty from separation of ingredients.

53. In work that will show, the **layers** are usually restricted to about 6 ins in depth, owing to the difficulty of spading the face work when the layers are thicker; but in foundations, and in heavy work above ground, if to be faced with masonry, or if appearance is not important, layers of wet conc as deep as 2 feet may be used.

54. If the conc, after placing, is found to be **too wet**, it is better to correct the trouble by placing drier conc upon it. When surplus water is bailed out, some cem is carried with it and thus wasted.

55. Excessive face spading brings up water from below, and this washes cem from the face.

56. Works of considerable length, such as dams and walls, are commonly built in sections alternately, thus: secs 1, 3, 5, etc, are first built separately, and, when they have hardened, sec 2 is built betw secs 1 and 3, section 4 betw secs 3 and 5, etc. The sides of secs 1, 3, 5, etc, thus serve as part of the forms for secs 2, 4, etc. This method facilitates bonding betw the secs, by means of vertical dove-tail grooves, formed, by the molds, in the sides of the secs first built. The conc of the remaining secs, placed later, enters and fills these grooves.

57. In freezing weather, conc can be laid in large masses in water or below the ground surf. In excavations, if the ground water is permitted to rise over the work during the night, it will usually prevent frost from reaching the conc.

58. At Chaudière water power dam, conc was laid in **temps as low as −20° F.** A mixing house was erected, and the temp, within, was kept, by stoves, above freezing. Materials were lowered into the house by derricks thru hatchways in the roof. Water was kept in casks, and kept lukewarm by steam jets. Sand was heated outside the house. Stone, in piles 3 to 4 ft deep, was heated (but not dried) by steam jets from a perforated pipe, passing under the piles. After placing, the conc was loosely covered with canvas, under which the nozzle of a steam hose was introduced.

Forms.

59. In wall foundations, the trench itself may constitute the form; and, in dams and arches of conc blocks, the first blocks, placed alternately, often serve as parts of the forms for the remaining blocks; but ordinarily a considerable amount of timber framing is required. See ¶ 56.

60. The **economy** of the work depends so largely upon the **design** of the forms, that it is often advisable to modify the design of the work itself, or to use more conc than would otherwise be nec'y, in order to secure economy. The design should be such that commercial sizes of lumber may be used, and with a min of wasteful cutting; and such that the forms may be readily erected and removed with a minimum of damage to themselves and no damage to the work, and used repeatedly. Where practicable, the forms are made in sections, small enough to be conveniently moved and handled separately. Cutting is economically done by power saw benches.

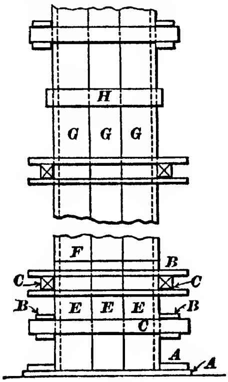
61. Even in building work, where much of the "centering" must be built in place, and where it can be removed only by taking it to pieces, the lumber may be used two or three times before it is discarded. Where the forms can be assembled in **panels**, and these panels removed as units, they may be used many times.

62. The requirements of different works, executed under diff conditions, vary so widely, that no useful details, as to the construction of the forms, etc, except for buildings (see ¶¶ 63 etc), can be given within the limits at our disposal. The designer should witness the *removal* of his forms before estimating their success.

Forms for Buildings.

63. In reinfd building construction, the forms are chiefly:
(a) Column forms,
(b) Beam, slab, floor and roof forms,
(c) Wall forms.

64. A typical **column form,** Figs 1 and 2. The boards, G, 1¼ ns thick, are held in place by cleats, H, 1¼ × 5 ins, and by "column clips," C, made of pieces 4 × 4 ins, and boards, B, 1¼ × 5 ins. These 'column clips" must be spaced to take the pres due to the conc. At the bottom of a column 18 ft high, they should be ≯ 10 ins, cen to cen. At the bottom, 4 boards, A, are used, to hold the form in shape, and the boards, G, are cut, on one side of the box, at F, 2 or 3 ft from the bottom, to form a door (cleats, on door, not shown), thru which all rubbish may be brushed. The door is then held shut by the lower two "column clips," and the form is filled Triangular fillets, T, are used to bevel the corners of the col.



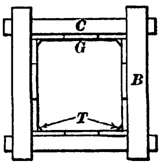


Fig 2.

Fig 1.

Figs 1 and 2. Column Form.

65. Column forms should be so designed that they may be removed without disturbing the forms for the beams and girders. The col forms may then be bared for inspection, before being loaded.

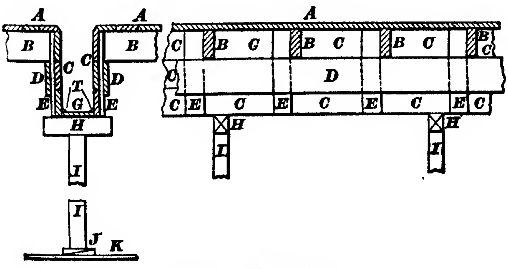

Fig 3. Beam Form.

66. Typical **beam or girder forms.** Fig 3. The forms, or beam-boxes, often miscalled "centers," are supported, betw columns, by temporary struts or shores, *I*, 4 × 4 ins, about 6 ft apart, resting on wedges, *J*, and the plank *K*. Corbels, *H*, 4 × 4 ins, are placed directly under the bottoms, *G* (1¼ ins thick) and sides, *C* (1¼ ins thick), of the beam boxes. The sides, *C*, are held together by cleats, *E*, 1¼ × 5 ins, 2 ft apart, to which are nailed the strips, *D* (1¼ × 6 ins), upon which rest the ledgers, *B*, 2 × 6 ins, about 27 ins apart. These support the panel boarding, *A*, 1¼ ins thick; and this, in turn, supports the slabs. Small triangular fillets, *T*, in the corners of the beam boxes, make the box tight and give beveled corners to the beam. Beam forms should be given a slight camber.

67. Typical **forms for floors** betw steel beams, Figs 4 to 6, vary with span and load. The forms are hung from the bottom flange of the I-beams, by "hanger bolts," *A*, Figs 4 and 6, ⅝ inch diam, with washers and handle nuts. These bolts secure the pieces, *E*, of 2 × 4 or 3 × 4, upon

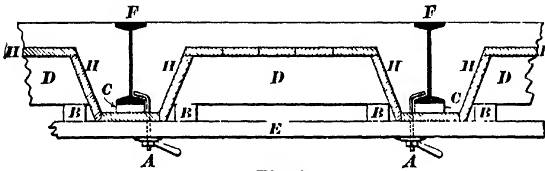

Fig 4.

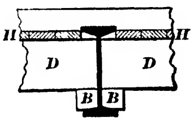

Fig 5.

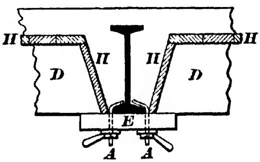

Fig 6.

Figs 4, 5 and 6. Floor Forms.

which the boards, *H H H* are supported by 2 × 6 or 2 × 8 ledgers, *D* (about 27 ins c to c, for ⅞ inch boards). Wooden blocks or sticks, *B*, Figs 4 and 5, are sometimes used under the ledgers to reduce their depth. Short conc blocks, *C*, Fig 4, are used, to keep the forms away from the lower flange of the steel beam. These remain permanently in the work. In order to promote adhesion betw the lower flanges of the I-beams and the thin mass of conc below them, the flanges are often wrapped with metal lath, before the blocks, etc, are placed.

68. Wall forms are usually made up in panels, so that they can be used several times. The panels are cleated together, and are usually about 3 × 12 ft. The panels are kept at the proper dist apart by separators, of wood or conc, and are held in place by bolts or wire ties. When wood separators are used, they must be removed just ahead of the concreting. Conc block or tube separators are sometimes used. These remain in the wall. When bolts are used that are to be later withdrawn and used again, they should be loosened by means of a wrench, about 24 hours after concreting; otherwise it will be difficult to remove them.

69. In the **Wiederholdt** system of reinfd conc wall construction. the conc is deposited within small hollow tile blocks, which form the finished exterior surface, and no wooden or other temporary forms are used. The blocks are shaped to meet the requirements of the work. Tiling and concreting are carried up simultaneously.

70. To reduce the cost of forms in reinfd building construction, columns, beams, slabs, etc, may be **cast on the ground**, and afterward erected and placed as desired; at the sacrifice, however, of the rigidity due to the monolithic character of ordinary reinfd work.

71. Metal forms. When the structure is of small and uniform cross section, permitting the repeated use of the same forms, as in sewers, conduits, tunnels, etc, the lagging, for the wooden forms, may be of sheet metal. In tunnels and similar works, of considerable extent, and in small ornamental work, forms composed entirely of metal may be used.

72. Both careless and over-careful **alignment** are to be avoided. Mr. W. J. Douglas (E N '06/Dec/20, p 646) suggests the allowance of "⅜ inch departure from established lines on 'finished' work, 2 ins on 'unfinished' work."

73. Avoid fine detail, and detail with sharp angles. Corners should be rounded or beveled, to facilitate the flow of conc and the removal of forms, and to render the corners less liable to subsequent injury.

74. Wooden forms, within which the conc is to be placed, should be fairly watertight, smooth, and of sufficient strgth and stiffness to hold to line under the pres of the green conc.

75. The forms are usually of dimensioned timber, faced with planed boards or planks. The opening of joints betw the planks may be partially prevented by the use of matched boards or of tongued-and-grooved plank.

76. Mortar, exuding thru open joints, leaves voids or stone pockets on the surface. Hence, in forms for facework, joints **should be made tight**, if necessary, by the use of mortar, putty, plaster of Paris, sheathing paper or thin metal.

77. If the lumber is very dry, when fastened in place, its swelling, due to its absorption of moisture, may bulge the boards and produce unsightly work. In such cases, the boards should not be matched, but should have their edges slightly beveled, and the sharp angle of the edges of adjacent boards placed in contact. Swelling will then crush the edges rather than bulge the board.

Lumber for Forms.

78. White pine is best for fine face-work, and quite essential for ornamental construction when cast in wooden forms.

79. Spruce, fir, Norway pine and the softer kinds of Southern pine are more liable to warp than white pine, but are generally stiffer and therefore better for struts and braces.

80. Partially dry lumber is usually best. Kiln dried lumber is unsuitable, as it swells when the wet conc touches it. In very green lumber, especially Southern pine, the joints are apt to open. Green lumber is heavy, and does not hold nails well.

81. For wall-panel forms, tongued-and-grooved or bevel-edge stuff is preferable to square-edge. Tongued-and-grooved gives smoother surface and less opening of joints, than square or bevel edge, but is more expensive, owing to waste in dressing, and there is more wear at joints if the forms are used often.

82. Even for rough forms, planing on one side may save money by reducing the cost of cleaning after using. Studs should always be planed on one side, to bring them to size.

83. Thickness. For ordinary walls, 1½ ins; for heavy construction, using derricks, 2 ins. For floor panels, 1 inch boards are most used; but, in tall buildings, they become much worn, and give bad finish to under sides of floors. For sides of girders, 1 inch or 1½ inch answers, but 2 inch is better for bottoms. Col forms usually of 2 inch plank.

84. Studding is usually from 3 × 4 to 4 × 6 inch; 4 × 4 inch is the most useful size. Spacing, usually 2 ft for 1 inch boards, 4 ft for 1½ inch, 5 ft for 2 inch.

85. Since beams and columns sustain greater stresses than floor slabs, their forms should be left in place longer, and should therefore be independent of the slab forms.

86. Sides of beam forms should be clamped or wedged together, to pre-

vent their springing away from the bottom boards, under the pressure of the conc.

87. Hardwood **wedges,** at tops and bottoms of struts facilitate the setting and removing of the struts, and testing for deflection.

88. Light joists (say 2 × 8 or 2 × 10), with frequent shores, are preferable to heavier sizes, difficult to handle.

Strength of Forms.

89. The **strength, required** for the forms, may be estimated, where wet conc is used, by assuming the pres of the conc as equal to that of a liquid weighing about 150 lbs per cu ft.* If dry and hard-rammed conc be used, the wedging of the stone, due to the tamping, will considerably increase the pressure.

90. Permissible loads, in lbs, on wooden struts for floor construction.

Unsupported length, ft	Cross section of strut, inches							
	3 × 4 = 12		4 × 4 = 16		6 × 6 = 36		8 × 8 = 64	
	per sq in	total	per sq in	total	per sq in	total	per sq in	total
14	—	—	700	11200	900	32400	1100	70400
12	600	7200	800	12800	1000	36000	1200	76800
10	700	8400	900	14400	1100	39600	1200	76800
8	850	10200	1050	16800	1200	43200	1200	76800
6	1000	12000	1200	19200	1200	43200	1200	76800

91. In timber beams, calculated for strgth, the **extreme fiber stress** is to be taken at 750 lbs per sq inch.

92. Construction live load, liable to come upon conc while setting, 75 lbs per sq ft on slabs; 50 lbs per sq ft in figuring beam and girder forms. This includes weight of men, barrows filled with conc, and structural material piled on floor, but not piles of cem sand or stone, which should not be permitted unless specially provided for.

93. Floor forms should be based upon allowable *deflection*, rather than upon *strength*. Formula:

$$d = \frac{3\,W\,L^3}{384\,E\,I}; \qquad I = \frac{b\,h^3}{12}.$$

where

d = deflection, ins;
W = total load on plank or timber;
L = distance, ins, between supports;
E = elastic modulus of lumber used = 1,300,000 lbs per sq inch;
I = moment of inertia of cross section of plank or joist;
b = breadth of plank or joist;
h = depth of plank or joist.

In the usual formula for deflection (see p 480) 1/384 is the coeff for beams with fixed ends, while 5/384 is that for merely supported ends.

Weight of conc, including reinforcemt, 154 lbs per cub ft.

(Sanford E. Thompson, Assn Am Portland Cem Mfrs, Bulletin 13, 1907.)

Details of Forms.

94. Too much **nailing** increases the difficulty of taking the forms apart without injury. Wire nails can be pulled with less damage to the wood than can cut nails.

* Mr. W. J. Douglas (E N, '06/Dec/20, p 646) assumes that the conc is a liquid of ½ its own weight, or 75 lbs per cub ft.

95. Iron or steel wall ties, extending thru the wall and fastening the forms in place, are usually removed and used again, if > ¼ inch in diam. If ≯ ¼ inch diam, they are usually allowed to remain; but, if their ends reach to the outer surface of the wall, they produce unsightly rust stains. To prevent this, the conc, surrounding their ends, is chipped out, and the rods are cut off, back from the surface. The holes, thus formed, are afterward plugged with mortar.

96. Separators (patented by Wm. T. McCarthy, 1 Madison Ave., New York city), molded of cem mortar, in the form of hollow cylinders, and in lengths of 4 and 6 ins, encircling the bolts, are sometimes used After the bolt is withdrawn, the hole in the cyl is filled with mortar.

97. Forms are liable to disturbance by blows from the conc bucket, or by the running of machinery in contact with the forms.

98. Any conc, adhering to a form, must be removed before the form is again used.

Adhesion to Forms.

99. Adhesion to forms. If the wood is new, and if the forms are thoroly wet before conc is placed, the conc, if hard, is not apt to adhere to the forms when these are removed. If the forms are to be removed before the conc is hard, they should, before concreting, be greased with material thin enough to flow and fill the grain of the wood. Crude oil, linseed oil, soft soap and other lubricating substances are used

100. New work is apt to adhere to old sticks, where conc has previously adhered, even tho this has been cleaned off.

101. Oil, applied to forms (to prevent their absorption of water or to facilitate their removal, ¶ 99), is apt to find its way to joints betw old and new work, and prevent the formation of a satisfactory bond. Soap and soft soap are of course harmless in this respect.

Removal of Forms.

102. Premature removal of forms and props has caused **many failures** of conc buildings; but undue delay, in their removal, means delay in the work and increase in the number of forms reqd.

103. The French law requires that **test blocks** and sample beams be made for every section cast. These enable the engineer to judge intelligently as to the condition of the actual work.

104. Props should be removed from *one beam or girder only* at a time, and should be at once replaced after the forms for that beam have been removed. This permits the discovery and repair of defects.

105. The **forms may be removed earlier** in warm and dry than in cold and damp weather, earlier from under light than from under heavy loads, earlier with quick-setting than with slow-setting cem, and earlier with dry than with wet mixtures. See Specifications, p 1359.

106. To release the beam boxes, the posts may be supported on wedges and capped. The posts and caps should not be removed, from more than one beam at a time. After the beam boxes have been removed, the posts and caps should be replaced before removing the forms from any other beams. Or, the posts may be supported solidly, and capped with a corbel forming the bottom and supporting the side-boards of the beam boxes. The side-boards may then be removed, leaving the posts and corbels undisturbed.

107. Prying against the conc, in removing the forms, may injure it.

Joints in Concrete.

108. Difficulty. In large work, the joints, betw work done on diff days or even before and after an hour's interval, are apt to give trouble, especially where watertightness is reqd.

109. Causes. The difficulty appears to be due partly to a surface skin or glaze, on the surf of the hardened conc, and partly to the presence of oily or dusty materials, laitance or sawdust, betw the two surfs. Oil, used upon the forms, or saturating the clothing of the workmen, is apt to find its way to the joints. Sawdust is particularly difficult to remove. The bond is especially weak if the older surf is frozen.

110. Remedies. Many remedies have been proposed, advertised and used, but none has been fully tested by time. See Specifications, p 1358. Cleanliness of surface and the use of wet mixtures are probably the best preventives. Water, used in scrubbing joints, should be rinsed off with clean water. A jet of live high-pres steam is very effective, removing even sawdust. Hydrochloric acid is used to advantage. Patented methods of securing bond, at joints, include the use of metallic binders, with their ends left projecting from the older surf, to bond with the newer. Another method employs a layer of prepared honey-comb slag, sprinkled over the still soft older surf; loose slag being removed after the hardening of the older surf and before the placing of the newer material.

111. Where conc is used in **reinforcing** and protecting **old stone masonry**, a stone should be removed here and there from the old masonry, and the joints cleaned out and washed. Key-bolts, with large washers on their heads, may also be driven into the face and left projecting into the concrete. The conc should also be carried far enough down the back of the wall to prevent water from working down into the horizontal joints on the tops of the wing walls and main walls.

Ramming.

112. Ramming of conc is necessary only with relatively dry mixtures. When properly done, it consolidates the mass about 5 or 6 %, rendering it less porous, and very materially stronger. For rammers, see spec'ns, p 1357 The men, using them, if standing on the conc, should wear gum boots.

113. Under water, ramming can be done only partially, and when the conc is enclosed in bags. A rake may be used gently for leveling loosely deposited conc under water.

114. Ramming should be discontinued before setting commences. Excessive ramming disturbs the homogeneity of the conc.

Placing under Water.

115. Concrete may readily be deposited under water in the usual way of lowering it, soon after it is mixed, in a dredge bucket, or in a V-shaped box of wood or plate iron, with a lid that may be closed while the box descends. The lid, however, is often omitted. This box is so arranged that, on reaching bottom, a pin may be drawn out by a cord reaching to the surf, thus permitting one of the sloping sides to swing open below, and allow the conc to fall out. The box is then raised to be refilled. In large works the box may contain a cu yd or more, and should be suspended from a traveling crane, by which it can readily be brought over any required spot in the work. The conc may if necessary be gently leveled by a rake soon after it leaves the box. Its consistency and strgth will of course be impaired by falling thru the water from the box; and moreover it cannot be rammed under water without still greater injury. Conc has been safely deposited in the above-mentioned manner in depths of 50 ft.

116. The Tremie, sometimes used for depositing conc under water, is a box of wood or of plate iron, round or square, open at top and bottom, and of a length suited to the depth of water. It may be about 18 ins diam. Its top, which is always kept above water, is hopper-shaped, for receiving the conc more readily. It is moved laterally and vertically by a traveling crane or other device suited to the case. In commencing operations, its lower end resting on the river bottom, it is first entirely filled with conc, which (to prevent its being washed to pieces by falling through the water in the tremie) is lowered in a cylindrical tub, with a bottom somewhat like the box described in ¶ 115, which can be opened when it arrives at its proper place. When filled, the tremie is kept so by fresh conc, thrown into the hopper to supply the place of that which gradually falls out below, as the tremie is lifted a little to allow it to do so. The weight of the filled tremie compacts the conc as it is deposited. A tremie had better widen out downward to allow the conc to fall out more readily.

117. The area upon which the conc is deposited must previously be surrounded by some kind of inclosure, to prevent the conc from spreading beyond its proper limits; and to serve as a mold to give it its intended shape. This inclosure must be so strong that its sides may not be bulged outward by the weight of the conc. It is usually a close crib of timber or plate iron without a bottom; and will remain after the work is done. If of timber it may require an outer row of cells, to be filled with stone or gravel for sink-

ng it into place. Care must be taken to prevent the escape of the conc hrough open spaces under the sides of the crib or inclosure. To this end he crib may be scribed to suit the inequalities of the bottom when the latter annot readily be leveled off. Or inside sheet piles will be better in some ases; or an outer or inner broad flap of tarpaulin may be fastened all around he lower edge of the crib, and be weighted with stone or gravel to keep it in place on the bottom. Broken stone or gravel or even earth (the last two where there is no current), heaped up outside of a weak crib, will prevent the bulging outward of its sides by the pressure of the conc. After the conc has been carried up to within some ft of low water, and leveled off, the masonry may be started upon it by means of a caisson, or by men in diving suits. Or, if the conc reaches very nearly to low water, a first deep course of stone may be laid, and the work thus brought at once above low water without any such aids.

118. The concrete should extend out from 2 to 5 ft (according to the case) beyond the base of the masonry. All soft mud should be removed before depositing conc.

119. Bags partly filled with concrete, and merely thrown into he water, are used in certain cases. If the texture of the bags is slightly open, a portion of the cem paste oozes out, and binds the whole into a tolerably compact mass. Such bags, by the aid of divers, are employed for stopping leaks, underpinning, and various other purposes, that may suggest hemselves. Such bags may be rammed to some extent.

120. Tarpaulin may be spread over deep seams in rock to prevent the loss of conc, and, in some cases, to prevent it from being washed away by springs.

121. Concrete, placed in water, should be in **large batches,** in order that the ratio of exposed surface to vol may be small. In running water, lead off the flow in pipes or shutes or by means of bulkheads (for which bag conc is suitable). If water is pumped out of the pit while concreting, it is apt to take cem with it. Observe the water flowing from the pump for indications of loss of cem.

122. Conc **dock foundation** on rock 14 to 19 ft below low water and covered with mud. Laid with assistance of diver. Mud washed off by jet. Rock not leveled. Wooden forms built on rock. Spaces, under forms, filled with bags of conc. Forms held down by means of boxes loaded with broken stone, anchored, by wire cables, near bottom, to neighboring piles, and braced, at top, by cross pieces nailed to existing dock. Conc lowered, by derrick, in ½ yd bottom-dump bucket, and dumped when close to work. The only cem lost is the little which washes from top of bucket load as bucket is submerged. The work has smooth faces along the forms, and appears to be perfectly homogeneous. (E R, '05/Oct/21, p 468.)

123. Placing conc **in 90 ft water,** in shaft, to stop inrush of water at bottom of shaft. Conc fed, by hopper, into 8 inch screw-jointed wrought iron pipe, lower end stopt with wood plug and resting on bottom of shaft. When the pipe was raised slightly, the plug refused to move and release conc. Pipe withdrawn, taken apart, and each section emptied. Plug, not tight, had allowed lowest section to fill with water, which disintegrated the conc, leaving, at top of lowest section, a plug of neat cem, which prevented the conc, above, from pushing out the wood plug as intended. Expt repeated, with tight plug. Inside the 8 inch pipe was placed a 1½ inch pipe, by means of which the wood plug was knocked out, allowing conc to descend. Rate regulated by changing dist of foot of pipe above bottom of shaft. Mass of conc, 10 or 12 ft thick, deposited. The upper 6 or 8 ins never set; but the remainder appeared to be solid and homogeneous. (Assn C E, Cornell Univ, Trans, 1898, p 74.)

124. In a case where hollow iron piles, in clean sandy bottom, were filled with conc, some of the mortar leaked out, and formed, with the surrounding sand, masses of conc, which adhered most tenaciously to the piles; suggesting the use of **hollow piles, purposely perforated,** in their lower portions, with small holes, thru which grout, poured into them, at top, can escape into the sand. (Chas List, Jour Assn Engg Socs, March, 1903, Vol 30, No 3, p 124.)

125. Superior Entry, Wis. Mixer discharges into a **sub-hopper,** with a cut-off shute, which discharges into depositing buckets on cars under the platform. Upon reaching the work, the buckets are lowered into the sub-

110. Remedies. Many remedies have been proposed, advertised and used, but none has been fully tested by time. See Specifications, p 1358. Cleanliness of surface and the use of wet mixtures are probably the best preventives. Water, used in scrubbing joints, should be rinsed off with clean water. A jet of live high-pres steam is very effective, removing even sawdust. Hydrochloric acid is used to advantage. Patented methods of securing bond, at joints, include the use of metallic binders, with their ends left projecting from the older surf, to bond with the newer. Another method employs a layer of prepared honey-comb slag, sprinkled over the still soft older surf; loose slag being removed after the hardening of the older surf and before the placing of the newer material.

111. Where conc is used in **reinforcing** and protecting **old stone masonry**, a stone should be removed here and there from the old masonry, and the joints cleaned out and washed. Key-bolts, with large washers on their heads, may also be driven into the face and left projecting into the concrete. The conc should also be carried far enough down the back of the wall to prevent water from working down into the horizontal joints on the tops of the wing walls and main walls.

Ramming.

112. Ramming of conc is necessary only with relatively dry mixtures. When properly done, it consolidates the mass about 5 or 6 %, rendering it less porous, and very materially stronger. For rammers, see spec'ns, p 1357 The men, using them, if standing on the conc, should wear gum boots.

113. Under water, ramming can be done only partially, and when the conc is enclosed in bags. A rake may be used gently for leveling loosely deposited conc under water.

114. Ramming should be discontinued before setting commences. Excessive ramming disturbs the homogeneity of the conc.

Placing under Water.

115. Concrete may readily be deposited under water in the usual way of lowering it, soon after it is mixed, in a dredge bucket, or in a V-shaped box of wood or plate iron, with a lid that may be closed while the box descends. The lid, however, is often omitted. This box is so arranged that, on reaching bottom, a pin may be drawn out by a cord reaching to the surf, thus permitting one of the sloping sides to swing open below, and allow the conc to fall out. The box is then raised to be refilled. In large works the box may contain a cu yd or more, and should be suspended from a traveling crane, by which it can readily be brought over any required spot in the work. The conc may if necessary be gently leveled by a rake soon after it leaves the box. Its consistency and strgth will of course be impaired by falling thru the water from the box; and moreover it cannot be rammed under water without still greater injury. Conc has been safely deposited in the above-mentioned manner in depths of 50 ft.

116. The Tremie, sometimes used for depositing conc under water, is a box of wood or of plate iron, round or square, open at top and bottom, and of a length suited to the depth of water. It may be about 18 ins diam. Its top, which is always kept above water, is hopper-shaped, for receiving the conc more readily. It is moved laterally and vertically by a traveling crane or other device suited to the case. In commencing operations, its lower end resting on the river bottom, it is first entirely filled with conc, which (to prevent its being washed to pieces by falling through the water in the tremie) is lowered in a cylindrical tub, with a bottom somewhat like the box described in ¶ 115, which can be opened when it arrives at its proper place. When filled, the tremie is kept so by fresh conc, thrown into the hopper to supply the place of that which gradually falls out below, as the tremie is lifted a little to allow it to do so. The weight of the filled tremie compacts the conc as it is deposited. A tremie had better widen out downward to allow the conc to fall out more readily.

117. The area upon which the conc is deposited must previously be surrounded by some kind of inclosure, to prevent the conc from spreading beyond its proper limits; and to serve as a mold to give it its intended shape. This inclosure must be so strong that its sides may not be bulged outward by the weight of the conc. It is usually a close crib of timber or plate iron without a bottom; and will remain after the work is done. If of timber it may require an outer row of cells, to be filled with stone or gravel for sink-

sion of the forms, and exposing the clean stone and sand of the conc. A few rubs of an ordinary house scrubbing brush, with a free flow of water to cut and to rinse clean, suffice; but a little additional rubbing improves the effect. The necessity for early removal of the forms, when this method is used, necessitates special care in their construction, increasing their cost. When applied to surfaces forming square corners, the projecting sand particles produce a ragged effect. Hence care should be taken not to extend the treatment to such corners.

136. An effect similar to that obtained by Mr. Quimby's method, may be produced, after hard set, by **washing with an acid solution,** which is afterward removed by the use of an alkaline wash, followed by water. This method attacks limestone in the agg.

137. Color effects are best produced by using *agg* of the desired color.

---

138. The difficulty of **making oil paint adhere** to fresh conc surfs is due to moisture and free lime. A wash of dilute acid neutralizes the lime, but is unsatisfactory, muriatic (hydrochloric) acid forming highly hygroscopic salts, such as calcium chloride, and sulfuric acid having only a superficial effect. Dissolve 10 lbs ammonia carbonate (salts of hartshorne) in 45 gals water, and apply once with a brush, or give several coats of a weaker solution, or apply as spray. The ammonia is liberated, and the carbonic acid forms, with the free lime, an insoluble carbonate, which soon becomes dry and hard. After exhaustive trials this was found the only method which satisfies every requirement. The amm carb keeps, for any length of time, in fairly tight vesesls. (Fred J. Bosse, "Cement Age," '09/Jan, p 48.)

PROPERTIES OF CONCRETE.

Weight. See Voids, p 1256, and Density, p 1257.

1. Weights of concrete, in pounds per cubic foot.
Broken stone or gravel **concrete,** 130 to 160; ordinarily 140 to 150.*

One foot B M = vol of a solid 1 ft square and 1 inch thick, = 144 cu ins = 1 cu ft/12.

144 lbs per cu ft = 1 lb per 12 cu ins = 1 lb per prism 1 inch square and 12 inches long.

Hence, **at 144 lbs per cu ft,** the wt of any prism in pounds = area of cross section in square inches, multiplied by length in feet, = vol in cubic inches/12.

Wt, lbs/cu ft..........	100	110	120	125	130	140	150	160
Kilograms/ cu meter....	1600	1760	1920	2000	2080	2240	2400	2560

Cinder concrete, ...	110 to 120;
Sandstone "	143
Limestone "	148
Gravel "	150
Trap "	155

With **natural** cem, 4 to 5 lbs lighter per cu ft

2. The unit weight varies not only with character of constituents, but also with proportions, consistency, degree of compacting, etc.

Permeability.

3. Even where the primary object of the conc is not the prevention of percolation by water, impermeability is of great importance in promoting the durability of the conc, and especially in protecting metal reinfmt from corrosion and from loss of adhesion with the conc.

4. Water may pass thru conc, etc, so slowly that evaporation, from the outside, proceeds more rapidly than the water can reach it, so that the outside of the **wall may appear dry,** altho percolation is actually taking place.

---

*144 lbs per cu ft = 12 lbs per ft B M (Board measure).
120 " " " " = 10 " " " "
108 " " " " = 9 " " " "

5. When made into hardened mortar, well trowelled down on all surfaces which come into contact with water, **neat cement is as nearly impermeable** as the best of natural rocks used for building purposes. (Wm. B. Fuller, Trans, A S C E, Vol 51, pp 133-4, Dec 1903.)

---

6. Mortar or conc, so proportioned as to obtain the **max practicable density**, and mixt rather wet, is impervious under ordinary conditions.

7. Small blocks of conc, carefully made from materials so graded as to insure great density, or with an excess of cem, have been repeatedly found to be as nearly impervious as the best natural stones. See Expts, p 1306.

8. In **large masses**, in actual construction, it is difficult to produce an absolutely tight structure without the addition of a **lining** of material more nearly impervious than the conc. Variations in the mixture, carelessness in manipulation or placing, or in bonding betw successive days' works (an hour's interruption, in the middle of a hot day, has been known to cause leakage), or insufficiency of water, will render conc permeable, in spite of proper theoretical proportioning and the addition of lime. The mix should be at least wet enough to settle into place with but little ramming

9. Conc, impervious in itself, may develop **cracks** thru which water may permeate. Reinfmt, properly placed, opposes such cracking.

10. Water may permeate thru the mortar, thru the particles of agg, or betw mortar and agg. Probably most of the percolation takes place thru the mortar. See Mortar. We here deal with those aspects of permeability which can better be discussed in connection with the conc as a composite material.

11. When the leakage consists of mere percolation thru the **minute pores** of conc, etc (*i e*, when there are no actual fissures), leakage generally diminishes with use, the water (even when apparently clear) blocking its own passage by depositing, in the pores of the material, either its own natural sediment, or (in the form of "laitance") lime and other compounds dissolved out of the conc itself.

12. This action depends upon many factors, notably the pressure, the sizes and shapes of the pores, the hardness and solubility of the material, and the character of the sediment carried by the water. Thus, under high pres, if the material is easily scoured, or if the pores are large and relatively straight, leakage may be expected to increase, rather than diminish, with time.

13. Where the nature of the case permits, as in floors, retaining walls, etc., it is better to lead the water off by proper **drainage**, than to attempt to block its passage by rendering the structure watertight.

14. Where watertightness is required, as in dams, the constituents must be carefully proportioned for max density, there must be an excess of rich mortar over vol of voids, dry mixtures should be avoided, the mixing must be thoro, and the construction should be, as nearly as possible, monolithic.

15. The application of **waterproofing materials** may be either (a) internal, mixt with the ingredients of the conc, (b) superficial, filling the pores near the surf; (c) external, preventing contact betw water and conc.

16. Internal. For water tight work, the vol of mortar should be 40 to 45 % of the vol of agg, or 40 to 42 % if the agg is graded. (Geo. W. Rafter, Trans, A S C E, Vol 42, p 149, Dec 1899.)

17. With agg having 35 % voids, the vol of mortar should be ≮ 50 % of vol of agg; vol of dry sand and cem ≮ ⅔ vol of agg; vol of sand ≯ 2 × vol cem. For cem leaving ≯ 10 % on No. 120 sieve, ordinary sands, and agg with 35 % voids, the following proportions are given:

cem	sand	agg	(sand + agg) ÷ cem
1	1.0	3.00	4.00
1	1.5	3.75	5 25
1	2.0	4.50	6.50

See Plain Concrete, ¶ 22, p 1256.

18. Every particle of sand must be coated with cem, and every particle of stone with mortar, so that the stones or the sand grains do not touch.

19. To insure this result, mix by means of one of the newer types of ma-

chine, introducing first the measured quantity of water and then the cem, making a liquid grout which will run easily into the most minute voids of the sand, which, being next introduced, becomes coated in the shortest space of time. The resulting mortar is still quite liquid, and flows into all the voids of the stone. (Wm. B. Fuller, Trans A S C E, Vol 51, p 135, Dec 1903.)

For the use of lime, see Expt. 82 *a*, p 1345.

20. In making thin slabs with a conc of 2 parts cem to 5 of fine bituminous ash, reinfd with poultry mesh, Mr. W. K. Hatt (Trans, A S C E, Vol 51, p 129, Dec 1903) employed a 5 % solution of ground alum, in place of one half of the gaging water, and a 7 % solution of soap in place of the other half. This strengthened and hardened the ash conc by about 50 %, and diminished its absorption by about 50 %. The soap solution alone diminished absorption, but did not strengthen the conc. Sand mortar was not greatly strengthened by the **soap and alum** treatmt, but its absorption was diminished about 50 %.

21. If joints are inevitable, they may be first wet, and then covered with neat cem paste or 1 : 1 cem mortar, upon which the new work is to be placed before the binding course hardens.

22. The permeability of conc linings of aqueducts &c may be diminished by drilling holes thru them and **forcing in grout** behind them by means of grout pumps. The grout sometimes appears at many points, indicating that it is passing not only thru the cracks but also thru the body of the conc. This method was successfully used in the Torresdale filtered water conduit, Philadelphia.

23. Superficial. For plastering the inside of a covered clear water well, Mr. Edwd Cunningham used 1.25 lbs of soft soap for each 5 buckets of water, and 3 lbs of alum per bag of cem. The mortar was easy to handle with the trowel, but had a nauseating odor. 2 coats, not more than 0.5 inch in all. 18-inch dividing wall showed no leak when one side held 16 ft of water. The soap was made of clarified fats, and cost 7.5 cts per lb; much too high. With 1 part cem to 2 parts sand, 6 to 9 gals of water and 12 lbs of alum were required for each bbl of cem. (Trans, A S C E, Vol 51, pp 127-8, Dec 1903.)

24. As an **external** treatment, Mr. Richd H. Gaines, New York Board of Water Supply (Trans, A S C E, Vol 59, p 160, Dec 1907) found the **Sylvester soap and alum process** (p 928), "fairly effective, but very expensive for large work."

25. Asphalt can be successfully applied only to dry surfaces. It becomes brittle and loses its efficiency upon oxidation; but it will often prevent leakage until the structure has become tight thru infiltration. See ¶ 11, p 1272.

26. The conc surface must be clean, and must first be treated with a thin wash of liquid asphalt, thinned with benzine. This enters the pores of the conc, and acts as a binder. Without this, the asphalt coating will not adhere to the conc.

27. Asphalt coatings should be made continuous, and should be protected against decay, from creeping and from abrasion, by being placed between alternate layers of conc, or by being covered with brickwork or masonry.

28. Tunnels, subways and basements, below water level, have been thoroughly waterproofed by continuous layers of heavy **roofing papers**, well mopped with tar or asphalt, and placed between outer and inner conc walls.

29. The two basins of Queen Lane reservoir, Philadelphia, originally lined with cem conc on sandy clay puddle, and holding 383 million gals of water 30 ft deep, were re-lined with Bermudez asphalt in 1896-7. The floor received 2 inches of asphalt conc, with a thin top layer of hot liquid asphalt; the slopes, two layers of hot liquid asphalt, with burlap between them; the burlap being anchored at top by being lapped around horizontal iron or wooden bars, let into the asphalt paving. While this work was in progress, the south basin of the Roxborough reservoir (147 million gals, 25 ft deep) was similarly lined. In the north basin, Alcatraz (California) asphalt was used, and the slopes, as well as the sides, were treated with asphalt conc. All four of these basins have since been in continuous use, without sensible leakage.

Elastic Modulus, E. See ¶¶ 12 and 13, p 1279.

30. When conc is subjected to compressive test, its stress-strain diagram is in general curved throughout its length; its elastic modulus,

$$E = \frac{\text{stress, per unit of area}}{\text{shortening, per unit of length}}, \text{ diminishing as the stress increases.}$$

Strength.

31. Conc being weak in tension, and brittle, its **tensile strength** is usually and properly **neglected:** dependence is placed chiefly upon its comp strgth, and its tensile and shearing strgths are usually exprest as fractions of the comp strgth.

32. The **compressive strength** is preferably determined experimentally by means of cubic specimens. The unit comp strgth decreases when the ratio, length/side, increases, and, in similar specimens, when their dimensions increase.

33. Conc **prisms, tested in endwise compression,** usually fail by shearing on planes oblique to the axes of the prisms. Upon these oblique planes, the unit shear is about half the ult comp stress.

34. The strgth varies widely with the character of the conc

35. For **12 inch cubes** of Portland cem mixtures having from 6 to 18 volumes of (sand + agg) to 1 vol cem, Mr. **Edwin Thacher** deduces, from the data of Expt 18 a, the straight-line formula,

$$S = M - N X$$

where

S = ult comp strgth, lbs per sq inch;
X = No of parts of sand to 1 part cem;
M and N = values as below:

Age =	7 days	1 month	3 months	6 months
M =	1800	3100	3820	4900
N =	200	350	460	600

Mr. Thacher holds that, for practical mixtures, "the strgth of conc depends principally on the strgth of the mortar, and not, to any great extent, upon the amount of stone." In these tests, the vol of stone was always twice the vol of sand.

36. But few tests have been made to determine the **tensile strength** of conc. It is usually taken as approximately from one-tenth to one-eighth the comp strength, and the **shearing strength** as from 1.2 to 1.5 times the tensile.

37. Prof. L. J. Johnson (Jour, Assn Eng Socs, Vol 38, No 6, p 310, June, 1907) tested 25 reinfd beams, 3 ins × 9 ins × 8 ft, loaded 6 ins from each support; 19 of the beams were of 1 : 2 : 2⅔ scaly trap; 6 of 1 : 2.5 : 5. All the **beams failed by slip of reinfmt:** the 1 : 2 : 2⅔ beams, 137 to 143 days old, successfully resisted shears of 233 to 573 lbs per sq in, av 470; and the 1 : 2.5 : 5 beams, 488 to 750; av 628.

38. In beams, owing to the rising of the neutral axis, under loading, the **ult unit fiber stress,** or rupture modulus, is about 1.6 × the unit tensile strgth.

Setting.

39. Setting is of course a function of the *cement paste.* See Mortar. We here treat of setting, as affecting the conc as a composite body

40. Temperature. In hot weather, conc sets very much faster than in cool weather, and the load may therefore be applied sooner in hot weather; but the time required varies with the class of structure and of conc.

41. Gradual loading. Where the loading is static or gradually increased, the time may be shorter than where the load is applied suddenly or is subject to impact.

42. "As a general rule, **bridge abutments and piers** of Portland cem conc should be allowed to set at least a month before using, if built during ordinary warm weather. If built during cold weather, their use should, if possible, be deferred until warm weather sets in." (W. A. Rogers, RR Gaz, '00/Jul/27. p 514.)

43. Steel girder spans have been placed upon Portland cem conc abutments without injury 2 weeks after the completion of the abuts in hot weather; but work of the same character, finished early in Dec, was found not very solid inside, early in the following March.

Effects of Heat and Cold.

44. **Freezing** nearly always damages **nat** cem mortar or conc to such an extent that it must be replaced by new material.

45. With **Portland** cem conc, **freezing suspends the setting** and hardening of the mortar, for the length of time during which the material has been frozen. The apparent loss of strgth, in frozen specimens, may often be due merely to such delay in setting.

46. While freezing seldom results in material reduction of the ult strgth of Port cem conc, yet it **may produce serious results** by giving the conc an apparent hardness; thus causing the premature removal of forms, or the imposition of undue loads, which may produce failure when the conc thaws out, if it had not already set sufficiently before being frozen.

47. If, soon after the mortar, thru the entire thickness of a wall, is frozen, the sun shines on one face of it, so as to soften the mortar of that face, while the mortar behind it remains hard, it is plain that the wall will be liable to settle at the heated face, and at least bend outward if it does not fall.

48. If the freezing does not take place until after the cem has taken its **initial set**, there is little danger. Thin work should not be done at < 28° F on a rising, or at < 32° on a falling temp.

49. **A thin scale** is likely to crack from the surface of conc walks or walls which have been frozen before the cem has hardened. Granolithic or troweled finish sometimes spalls up in small patches, when frozen.

Protection.

50. **Protection against freezing** is expensive and uncertain. Hence the placing of conc in freezing weather should be avoided when possible.

51. **Housing and heating** the finished work. Tents or screens may be used; but wooden sheds are more effective.

52. **Covering** the conc, as soon as placed, with canvas, cem bags or tar paper, or with a thick layer of sand, straw, manure, sawdust or other poor heat-conductors. Straw should be ≮ 1 foot deep. Manure is the best, but it discolors the work. Canvas etc should be kept an inch or two away from the conc, leaving an air space. Otherwise use two layers.

53. **Heating the materials.** Stone is frequently heated by piling it over a pipe or improvised oven, and building a fire inside; or over a coil of pipe containing numerous small holes, and then forcing steam thru the pipe. The conc must be used before the steam is condensed and frozen. Sand is heated over a long sheet iron stove.

54. **Lowering the freezing point of the mixing water,** by the addition of chemicals.

55. **Salt** is the cheapest and most commonly used material. It lowers the freezing point about 1.5° F for each 1 % salt added to the water. A 10 % solution (12 lbs salt per bbl of cem) reduces the freezing point to 17° F and does not injure the strgth of the conc. For 32° F, dissolve 1 lb salt in 18 gals water; add 3 oz salt for each 3° below 32° F. (Ch of Engrs, U. S. A. Report, 1895.) Larger percentages of salt appear to weaken the conc.

56. **Calcium chloride,** 15% solution, or 1.25 lbs per gal of water, lowers the freezing point to about 20° F, and does not weaken the mortar. It rapidly absorbs moisture, and it is possible that, if ground dry with the Portland cem clinker, even to the amount of 0.5 %, it would cause the material to gather dampness. The chloride dissolves with extreme rapidity and may be added to the mixing water. (Prof. R. C. Carpenter, Cornell Univ, Sibley Jour of Eng, Jan 1905.)

57 The major portion of a pile of sand or stone may be in condition for use altho the surface is frozen.

58. In winter, we may **reduce the areas** of the exposed layers of the work, by placing the bulkheads closer together. A day's work will then run to a greater elevation, and will necessitate the use of stronger forms.

59. **Mortars**, placed in open air, are more or less **injured, by drying** instead of *setting*, when the temperature exceeds about 65° to 70°; but if mixed only in small quantities at a time, and quickly laid in masonry of dampened stone, so as to be sheltered from the air, the injury is much reduced. The sand and stone should both be *damp*, not wet, in hot weather, and a *little* more water may be used in the cem paste; also, if possible, not *only the mortar*, while being mixed, but the masonry also, should then be *shaded.*

Expansion.

60. In variable climates, **cast iron cylinders, filled with concrete,** are frequently split horizontally by unequal expansion and contraction. In such structures it is safest to consider the cylinders as mere molds for the conc; and to depend only upon the conc for sustaining the load.

For **expansion coeffs**, see Reinforced Conc, ¶ 9, p 1278.

61. **Cracks and joints.** In abutments or culverts over 60 ft long, divide the wall into sections of about 40 ft, and finish one section before beginning the other. Contraction will cause the joint to open, and irregular cracks thru the body of the wall will thus be avoided. Short sections may be completed without stopping, and horizontal joints thus avoided "Very small cracks, which, in stone masonry, would be difficult to find, show up very plainly in conc." (W. A. Rogers, R R Gaz, '00/July 6, p 461.)

62. **Effect of high temperatures.** During calcination of the materials for Portland cem, the chemically combined water is driven off. When, in mixing, this water is returned to the material, hardening takes place; but the re-application of temperatures, sufficiently high to drive off the water again, reverses the hardening process and disintegrates the material.

Chemical Effects.

63. "**Dehydration** of the water of crystallization of conc probably begins at about 500° F and is completed at about 900° F"; but this cools surrounding masses, and thus increases the heat resistance of the conc. J. C.*

64. **Rehydration.** Briquets, kept, for 6 to 8 hours, at 1000° to 1200° F (not in contact with flame) and allowed to cool, showed practically no strgth; but 28 days immersion in water restored their strgth to that of unheated briquets.

65. **Fire resistance.** In quartz sand the expansion coeff is twice that of feldspar; and the expansion, in one direction, is twice that in the direction perp to it.

66. At the Baltimore fire the conc, exposed to flames, was seldom damaged to a greater depth than ½ inch, altho projecting corners were at some places rounded off by flames to a radius of about 2 inches.

67. **Sea water** has apparently but little effect upon conc so proportioned as to secure maximum density, and thoroly mixt. Damage by sea water, reported as taking place at the water line, has probably been due, in part, to freezing. J. C.*

68. Destructiv action upon conc by **electrolysis** appears to be due to abnormal conditions seldom occurring in practice. J. C.

69. Green conc is injured by **acids**; but first class conc, thoroly hardened, is appreciably affected only by strong acids which seriously injure other materials. J. C.

70. In the reclamation of arid land, where the soil is heavily charged with **alkaline salts**, conc, stone, brick, iron and other materials are injured under certain conditions, at ground water level. Such action can be prevented by the use of an insulating coating. J. C.

71. Conc properly made, and having its surface carefully finished and hardened, resists the action of petroleum and ordinary engine **oils**. Oils containing fat acids appear to injure conc. J. C.

72. Sulphurous and sulphuric acid **gases**, combined with moisture, corrode conc, especially if heated

Tests of Concrete in place.

73. **Tests of concrete in place** may be made by analysis of a core of conc, obtained with a **core drill,*** using chilled steel shot for cutting. The bore holes are afterward grouted.†

74. **The ratio of cement to sand,** in the mortar, is found by means of the amounts remaining undissolved in hydrochloric acid; sand and cem, of the kinds used, and mortar, taken from the core, being tested separately in this way. (Prof. R. L. Wales, in E N, '08/Jan 9, p 46.)

75. **The ratio of mortar to stone,** in the conc, is found (1) by actual separation and by weighing the stone and the mortar separately, or (2) by ascertaining separately, and comparing, the specific gravities of the stone, the mortar, and the conc.

* Made by Cyclone Drill Co., Orrville, O., including small drills, worked by hand.

† B. G. Cope, in E N, '08/Jan/9, p 41.

REINFORCED CONCRETE.

1. The tensile and shearing strengths of conc are low as compared with its comp strgth. Hence metal rods or shapes are embedded in conc structures in those portions subject to tensile and shearing stresses, and in such positions as to take those stresses.

2. Uses. Reinfmt is used chiefly in the tension-sustaining portions of beams and girders, (including floor-slabs), cols, walls, retaining walls, dams, etc; but it is useful also in many other cases; as for preventing hair cracks in surfaces, for which purpose a light web of metal (wire mesh expanded metal, etc) is placed a few inches back from the face; for preventing fracture due to unavoidable sudden changes in cross-section; for joining walls meeting at an angle and liable to settle away from each other; and in culverts, enabling them to withstand hor tension due to the outward pressure of the embankment. For this purpose old chains may be used, or light rails, with bolts driven thru the bolt-holes, to increase adhesion.

3. Safety. Modern reinfd conc buildings are practically monolithic, and therefore more rigid than skeleton steel construction.

4. On the other hand, in the steel building, the details are more accurately worked out, and the work is usually erected by skilled men, often employed by the steel mfrs; so that there is but little chance of damage to the material in erection; whereas, in reinfd conc work, the best material may be injured in the using, and the work thus rendered unsafe.

5. Good conc protects imbedded steel from **corrosion**, both above and below fresh or sea water level; but water may penetrate porous conc and corrode the metal. Conc laid very dry is apt to be porous.

6. The **steel,** used in reinfg conc, has its ult strgth usually betw 50,000 and 70,000 lbs per sq inch, and its elastic limit between 25,000 and 35,000 lbs per sq inch, but cold working may raise the elastic limit to 40,000 or 50,000 lbs per sq inch. "Deformed" bars are often rolled of steel with much higher elastic limit (50,000 to 65,000 lbs per sq in claimed) for the sake of economy of steel; but see Bar Reinforcement, pp 1296, etc. As in rolled iron and steel in general, the elastic modulus may be taken as averaging approximately 30,000,000 lbs per sq inch. See ¶ 11.

7. Concrete. In general the necessity of working the conc around the reinfg bars requires that the agg for the conc in reinfd work shall be smaller than would be permissible in unreinfd mass work; and the vital importance of adhesion requires that all the materials for the conc shall be of the best, and the mortar not too lean or too dry.

Expansion, Contraction, Etc.

8. The **shrinkage** of conc, while setting in air, produces comp stress in the reinfmt and tensile stress in the conc itself. Setting under water, the **expansion** of the conc produces the opposite effects.

9. The linear **expansion coefficient**, a, of a material, is that fraction of its original length which a bar of it gains or loses for each degree of change in its temp. Approximately:

	Per degree, Centigrade	Per degree, Fahrenheit
In steel .... 10,000 a =	0.117	0.065
In concrete .... 10,000 a =	0.108	0.060*

10. The large number of reinfd conc structures which have been exposed, for years, to wide extremes of temp, without injury thru difference in expansion, confirms the results of experiments, quoted above, as indicating that the diff, betw the expansion coefficients of the two materials, is negligible

Elastic Modulus.

11. The **elastic modulus, E_s, of rolled iron and steel,** of all kinds (p 460,) is remarkably uniform and constant, ranging ordinarily betw 27 and 31 (av, say 30) millions of lbs per sq inch = approx 1.9 to 2.2 (av, say 2.1) millions of kgs per sq cm.

---

* W D. Pence, 1 : 2 : 4 conc, Jour Westn Soc of Engrs, 1901, Vol. 6, p. 549, 10,000 a = 0.055 Fahr, results nearly uniform. Columbia Univ. 1 : 3 : 6 conc, 10,000 a = about 0.065 Fahr.

12. On the contrary, the **elastic modulus, E_c, of concrete** varies widely, not only as betw diff mixtures differently manipulated, and betw diff specimens made under like conditions from like materials, but in one and the same specimen under diff intensities of loading; so that, in stating the results of expts, it is usual to specify the range of unit stress within which the observations were made.

13. In **stone concrete, E_c** ranges from 1.5 to 4 (av, say 3) million lbs per sq inch, = 0.1 to 0.28 (av, say 0.21) million kgs per sq cm. See Expt 81 *a*, p 1172. In cinder conc, E_c is ordinarily from 20 to 50 % less than in stone conc. See ¶ 30, p 1274.

14. The ratio, n (sometimes called *r* and *R*), = E_s/E_c, betw the elastic moduli of steel and of conc respectively, is usually taken betw 10 and 15 for stone conc, with higher values for cinder conc. See Specifications, ¶ 107, p 1363. Owing to the variability of E_c (see ¶ 12), it cannot be a constant quantity, even during the range of a single experiment carried from zero load to rupture.

15. The ratio, *n*, is, however, of constant and **important** use in all calculations respecting the mutual behavior of conc and steel.

16. Considère's experiments (Expt 16 *a*, p 1314) seemed to show that conc, when reinfd (being constrained, by its adhesion to the steel, to share in its movemts), actually underwent, without fracture, far greater **elongations** than were possible in unreinfd conc, but later expts (36, 38, 81 *e*, 81 *f*), in which the conc surface was more closely observed have indicated that the supposed elongation of the conc was in fact due to the formation of cracks which had before escaped observation. If the adhesion, betw the conc and the steel, is uniform, the cracking must be evenly distributed over the area of contact, and the cracks must therefore be very numerous and very fine, probably so fine as not to endanger the materials thru the percolation of water.

Adhesion. See ¶ 58, p 1294.

17. With **rich and wet mixtures,** such as are used in reinfd construction, the cem adheres very closely to the steel.

18. After the adhesion proper has been overcome, the removal of the steel from the conc is still opposed by **friction** betw the two.

19. Upon the ability of this adhesion and friction to resist the forces tending to overcome them, depends of course the safety of the structure.

20. Both adhesion and friction, and particularly the friction, are greatly affected by the character of the conc and by its behavior under stress and under temp changes, by the method of testing, etc.

21 In direct **tests for adhesion,** whether the steel is pulled or pushed, the conc is always under comp, which causes some lateral expansion of the conc, and therefore increased pressure upon the reinfmt. Hence, the adhesion may be found higher than (other things equal) in beams, where this condition does not obtain.

22. On the other hand, where the hor reinfg bars, in a beam, are bent upward, near the ends, and pass up into the region of compression and (as is often the case) to a point over the support, the high pressures upon the bar, in those portions, may give it greater adhesion, as a whole, than could be the case with a straight bar under direct test.

23. With **great lengths of imbedment,** the stretch, in the steel, under high tensile stresses, may be such as to contract the steel laterally, sufficiently to reduce adhesion. Hence, tests where the steel is *pushed into* the conc, show higher adhesions.

24. Ultimate adhesion. In general, expts (see Expts 64 *a*, *b*) give, as the ultimate adhesion of good conc to plain round rods, from 200 to 300 lbs per sq inch of contact surface. With smooth round rods, in a beam, Kleinlogel (Beton und Eisen, 1904, pp 227 et seq) obtained 560 lbs per sq inch. The conditions of practice generally differ greatly from those obtaining in the laboratory.

25. Working bond stress. In beams subject to shock, about 50 lbs per sq inch; for quiet loading, about double this is sometimes allowed. See Specifications, ¶¶ 113–115.

REINFORCED CONCRETE COLUMNS.

1. A concrete column usually has longitudinal steel rods embedded, near the circumference, thruout its length. If there is no deflection, and no slip between the concrete and the steel, the two materials must shorten equally under load. Hence (p. 458, Eq (3)) if L = original length, l = change of length, a_s and a_c = cross section areas; s_s and s_c = unit stresses, E_s and E_c = elastic moduli, of steel and of conc. respectively; we have

$$s_s = E_s\, l/L; \quad s_c = E_c\, l/L, \qquad (1)$$

and, since l/L is necessarily the same for both materials,

$$s_s/s_c = E_s/E_c = n; \quad s_s = s_c\, n, \qquad (2)$$

and

total stress in steel $= a_s\, s_s = a_s\, s_c\, n$ ....(3)

" " " conc $= a_c\, s_c$ ....(4)

" " " column $= P = a_s\, s_s + a_c\, s_c = s_c\,(a_c + a_s\, n)$ ...(5)

$$a_c = P/s_c - a_s\, n \qquad (6)$$

$$s_c = P/(a_c + a_s\, n) \qquad (7)$$

2. Example. A square conc col 16 ins × 16 ins, 12 ft long has, embedded in each corner, a round steel rod 1 inch diam; cross section area of each rod = 0.785 sq inch. Permissible unit comp stress, s_c, on concrete, = 500 lbs per sq inch. Required the load which may be carried by the col. Here

Area, a_s, of steel = 4 × 0.785 = 3.14 sq ins;

Area, a_c, of conc = 16 × 16 — 3.14 = 253 sq ins;

E_s = 30,000,000 lbs per sq inch;

E_c = 2,500,000 lbs " " ";

$n = E_s/E_c = 12$,

Total stress taken by conc $= a_c\, s_c$ = 253 × 500 = 126,500 lbs

" " " " steel $= a_s\, s_c\, n$ = 3.14 × 500 × 12 = 18,840 lbs

" " " " column.......................145,340 lbs

3. Here the steel takes 100 × 18,840 ÷ 145,340 = about 13 % of the entire load, a safe proportion. This proportion should not exceed 20 %, or, at most 30 %.

4. A convenient rule is to count each sq inch of steel, in cols, as worth n sq ins of concrete.

5. Conservative designers load conc cols approximately as follows:

Length / diam	Mixture 1:1.5:3	1:2:4	1:2.5:5	1:3:6
	$p = P/a$ = Load, in lbs per sq inch.			
< 12	600	500	350	350
12 to 18	550	450	300	300

6. Longitudinal reinfg rods or **bars are usually placed** symmetrically near the outside of the conc, and are covered by from 1½ to 2 inches of conc. The rods should be tied together, by smaller rods or by wires, at intervals not exceeding the diam of the col.

7. Specifications usually require that the aggregrate cross-section **area of compression rods** shall not exceed from 2 to 3 % of the cross-section area of the col.

8. In buildings of say three or four stories, the **rods of each section are bent in, near their tops,** to form a cylinder, 18 or 20 ins high, of smaller diam than the main cyl below; and the section next above fits down over this portion, so that the two sections overlap the length of the reduced portion.

9. Owing to their much greater cross-section areas, and to the lower unit stresses in their materials, reinfd conc cols are much less liable to failure by deflection than are steel cols.

10. For **ultimate loads on longitudinally reinforced concrete columns liable to deflection,** we have the Rankine formula

$$p = \frac{P}{a} = \frac{s}{1 + m K^2} \quad \ldots\ldots (8)$$

where

P = ult total load on col;
a = cross section area of col;
p = P/a = ult unit load on col;
s = ult comp unit strgth of conc cubes;
K = L/r = length/least radius of gyration;
Prof. Morsch gives m = 0.0001. Eisenbetonbau, '08, p 73.

Hooped Columns.

11. Columns reinforced with hoops (or spirals) of steel, or with web reinforcement bent into cylindrical form, show high ult strgths and are largely used; but they undergo considerable deformation before the strgth of the hoops is developed, the hoops acting much like a steel cylinder, filled with sand, such cylinders being unable to act until the sand is compressed.

12. Expts at Watertown (Tests of Metals, 1905) show that, when the col is subjected to loads of from 100 to 1000 lbs per sq inch, the unit lateral deformation is less than one-fourth the unit longitudinal deformation. Thus, if the col shortened 0.0004 of its length, its diam increased less than 0.0001 of its original dimension.

13. From tests at the Univ of Illinois (Am Soc Testg Matls, Procs, 1907, p 382) Prof. A. N. Talbot derives the following **formulas** for the ult strgths of hooped cylindrical conc cols, 1 : 2 : 4, wet mixture, av age, 60 days; cols 12 ins diam, 10 ft long. Covering, over the hoops, generally < ¼ inch. Hoops, 1 inch wide, gage Nos 8, 12, 16, electrically welded, spaced generally 2 ins c. to c. Let

p = ult strgth of col, lbs per sq inch;
c = ratio of hooping to conc core;
1600 = comp strgth of conc, lbs per sq inch.

Then,

For mild steel, $p = 1600 + 65{,}000\, c$; ....(9)
" higher " $p = 1600 + 100{,}000\, c$. ....(10)

14. Assuming that the ult unit stress, in longitudinal col reinfmt, is 25 times that in the conc, the hooping gave additional ult strgth from 2 to 4 times that given by longitudinal reinfmt.

15. M. Considère's expts (Génie Civil, Nov 1902), with spirally reinforced conc cols, indicate that the bars, forming the hoops, should have a diam of approximately 1/40 of the diam of the col; that the pitch of the spirals (distance between hoops) should be from ⅛ to ⅙ the diam of the col; and that the steel, in the hoops or spirals, adds, to the ult resistance of the col, 2 4 times as much as the same weight of metal used as longitudinal reinfg. He gives the formula

Ultimate total load on col = $1.5\, a_c\, c + s_e\, (a + 2\,4\, A)$ ....(11)

where

a_c = cross section area of col inside of spiral;
c = ult comp unit strgth of plain conc in short blocks;
s_e = elastic limit of steel;
a = cross section area of existing longitudinal reinfmt;
A = " " " " longitudinal reinfmt of equal wt with the spiral.

$1.5\, a_c$ is taken as representing the area of the *entire* conc cross sec.

Column Footings.

16. In a **column footing**, the stresses are analogous to those in a floor slab resting upon a col; but, owing to the relatively limited spread of the footing, the moments and shears are heavy, requiring considerable depth. The heaviest stresses are under the edges of the col. Hor rods, in the footing, are analogous to rods near the top of a beam over the support; *i. e.*, they take negative moms, and some of them should be bent upward, or provided with stirrups, just beyond the edges of the col.

17. Figs 1 and 2 (T & M, pp 261, 262). Fig 1: Two series of main reinfg rods, *a a′*, *b b′*, crossing at right angles under the col, with diag rods,

REINFORCED CONCRETE BEAMS.

1. Conc is ordinarily from eight to ten times as strong in comp as in tension. Hence, in an unreinforced conc beam of rectangular section, under bending stresses, failure occurs on the tension side.

2. The ease with which steel can be embedded in conc, the practical equality of the expansion coeffs of the two substances, the strong adhesion between conc and steel and the practicability of supplementing this adhesion by lugs or other lateral projections from the surface of the steel, facilitate combinations in which the principal service of the conc is to resist comp, while that of the steel is to resist tension.

3. The method of manufacture of conc is such that its behavior, in a given case, is less certain than that of steel.

Owing to this and to uncertainty, as to the degree of adhesion betw conc and steel, on which their united action depends, the theory of such beams is at once more complicated and less exact than that of steel beams of economical sections. In the design of reinfd conc beams, proper allowance must be made for this fact, and extreme refinement is out of place.

General Theory.

4. Simple reinfd conc beam, of rectangular section, Fig. 1.

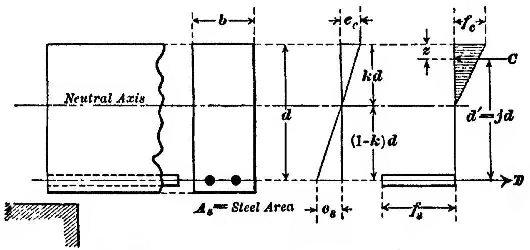

Fig 1. Reinforced Concrete Beam. Theory.

Fundamental assumptions.

1. Cross sections, plane before flexure, remain plane under flexure.
2 Initial stresses (from shrinkage, etc) are neglected.
3. No slipping occurs between conc and steel. Hence they deform equally.
4. The tensile resistance of the conc is neglected.
5. The elastic moduli, E_s and E_c, of steel and of conc respectively, and hence their ratio, $n = E_s/E_c$, remain constant.

5. Notation. Referring to Fig 1, let·

b = breadth of cross section of beam, perp to the paper;
d = dist from comp side of beam to cen of grav of steel;
kd = " " " " " " " neutral axis;
z = " " " " " " " resultant of comp forces;
$(1-k)\,d$ = " " cen of steel to neutral axis;
$d' = jd$ = " " " " " " resultant of comp forces
= leverage of resisting couple;
j = d'/d;

E_s = elastic modulus of steel; E_c = elastic modulus of concrete;
e_s = unit elongation of steel; e_c = unit shortening of concrete;*
f_s = unit tensile stress in steel †; f_c = unit comp stress in concrete;*†

* In the *outermost* fibers on the compression side of the beam.
† f_s and f_c are the *actual* unit stresses. See ¶ 13, p 1286.

a_s = cross-section area of steel; $a_c = b\,d$ = cross-section area of conc above cen of steel;
T = sum of tensile stresses in steel; C = sum of comp stresses in concrete;
$n = E_s/E_c$ = ratio of elastic moduli of steel and conc;
$p = a_s/a_c$ = ratio of steel area to that portion of conc area which is above cen of steel;*
$a_s = p\,a_c = p\,b\,d.$
M_s = resistg mom, based upon the max allowable value** of f_s;
M_c = resistg mom, based upon the max allowable value** of f_c;
M = actual resisting moment = c. b d².
For values of c (= M/bd^2) see Figs 2 and 3, pp. 1285, 1289.

Stresses, Moments, Design.

6. Figs 1 and 2§ and ¶¶ 7 to 20 illustrate the **relations existing between the important factors.** k, j, f_s, f_c, p, M_s, M_c and M; when neither f_s nor f_c exceeds the elastic limit. When they exceed that limit, see ¶¶ 21, 22, p 1290.

7. In equilibrium, the **bending moment** of the load (see p 474) is balanced by the equal **resisting moment** of the couple composed of the two equal hor forces, T and C, these forces being the resultants respectively of the tensile stresses in the steel and of the compressive stresses† in the conc.

8. The tensile stresses f_s, in the steel, are assumed to be uniformly distributed over its entire cross section, a_s; and their resultant, T, is therefore taken as acting at the grav cen of the steel area; but the **compressive stresses,** in the conc, in any cross sec, decrease uniformly‡ from a max, f_c, at the upper surf of the beam, to zero, at the neutral axis. Their resultant, C, is therefore applied at a point distant $kd/3$ below the top of the beam, kd being the distance from top of beam to neutral axis, and d the distance from top of beam to grav cen of steel.

9. Value of "j." The lever arm, d′, of the resisting couple is therefore

$$d' = jd = d - kd/3 = d\,(1 - k/3) \qquad (1)$$

and we have

$$j = d'/d = 1 - k/3 \qquad (2)$$

For approx values of j, see ¶ 12.

10. Value of "k." From assumption 1, ¶ 4 we have

$$e_c/e_s = k/(1-k) \qquad (3)$$

From assumption 5, we have

$$f_c = e_c E_c; \quad f_s = e_s E_s \qquad (4)$$

Hence

$$\frac{f_c}{f_s} = \frac{e_c\,E_c}{e_s\,E_s} = \frac{k}{1-k}\cdot\frac{E_c}{E_s} = \frac{k}{n\,(1-k)} \qquad (4a)$$

For equilibrium, $C = T$; but

$$C = f_c\,b\,k\,d/2 = e_c\,E_c\,b\,k\,d/2 \qquad (5)$$

and $$T = f_s\,a_s = f_s\,p\,b\,d = e_s\,E_s\,p\,b\,d \qquad (6)$$

Hence, $k = 2\,p\,\dfrac{e_s\,E_s}{e_c\,E_c} = 2\,p\,n\,\dfrac{1-k}{k}$;

or:

$$\mathbf{k} = \sqrt{(p\,n)^2 + 2\,p\,n} - p\,n \qquad (7)$$

---

† Below the neutral axis, the conc is in *tension*, but its tensile stress is neglected. See assumption 4, ¶ 4, p 1283. ‡ See ¶¶ 21, 22.
§ Figs 2 and 3 are by Prof A. W. French, A S C E, Trans, Vol 56, '06, pp 362, etc.

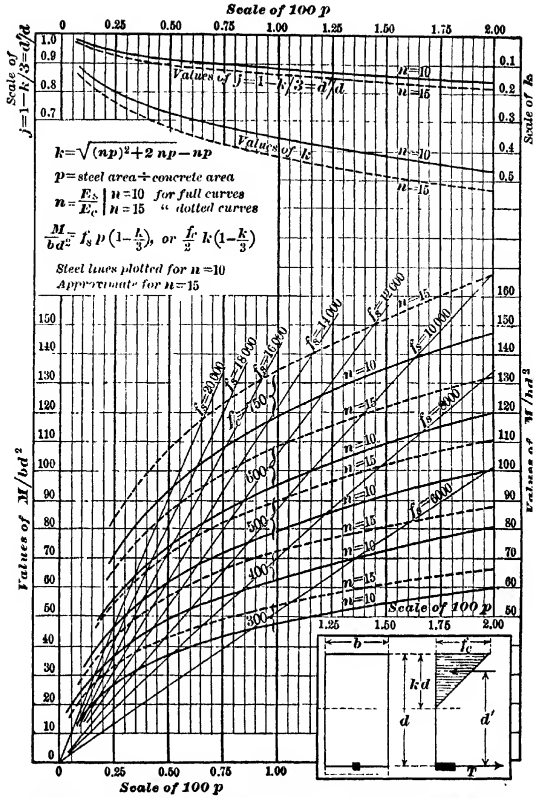

Fig 2. For Working Stresses. (For ultimate stresses, see Fig 3.)

k = $\sqrt{(p\,n)^2 + 2\,p\,n} - p\,n$, **j** = d' / d,

$\mathbf{f_s}$ = unit stress in steel, $\mathbf{f_c}$ = unit stress in conc at top of beam,

p = a_s/a_c = ratio of steel area to conc area,

$\mathbf{M_s}$, $\mathbf{M_c}$ = resistg mom, based upon allowed value of f_s, f_c, resp,

M = resistg mom, actual.

$$\frac{M}{b\,d^2} = f_s\,p\,(1 - \frac{k}{3}) \quad \text{or} \quad \frac{f_c}{2}\,k\,(1 - \frac{k}{3}).$$

$n = E_s/E_c$. **Solid curves** represent $n = 10$; **dotted curves,** $n = 1$
Steel lines plotted for $n = 10$; approx for $n = 15$.

a_s = cross-section area of steel; $a_c = b\,d$ = cross-section area of conc above cen of steel;

T = sum of tensile stresses in steel; C = sum of comp stresses in concrete;

$n = E_s/E_c$ = ratio of elastic moduli of steel and conc;

$p = a_s/a_c$ = ratio of steel area to that portion of conc area which is above cen of steel;*

$a_s = p\,a_c = p\,b\,d$.

M_s = resistg mom, based upon the max allowable value** of f_s;

M_c = resistg mom, based upon the max allowable value** of f_c;

M = actual resisting moment = c. b d².

For values of c (= M/bd^2) see Figs 2 and 3, pp. 1285, 1289.

Stresses, Moments, Design.

6. Figs 1 and 2§ and ¶¶ 7 to 20 illustrate the **relations existing between the important factors.** k, j, f_s, f_c, p, M_s, M_c and M; when neither f_s nor f_c exceeds the elastic limit. When they exceed that limit, see ¶¶ 21, 22, p 1290.

7. In equilibrium, the **bending moment** of the load (see p 474) is balanced by the equal **resisting moment** of the couple composed of the two equal hor forces, T and C, these forces being the resultants respectively of the tensile stresses in the steel and of the compressive stresses† in the conc.

8. The tensile stresses f_s, in the steel, are assumed to be uniformly distributed over its entire cross section, a_s; and their resultant, T, is therefore taken as acting at the grav cen of the steel area; but the **compressive stresses,** in the conc, in any cross sec, decrease uniformly‡ from a max, f_c, at the upper surf of the beam, to zero, at the neutral axis. Their resultant, C, is therefore applied at a point distant $kd/3$ below the top of the beam, kd being the distance from top of beam to neutral axis, and d the distance from top of beam to grav cen of steel.

9. Value of "j." The lever arm, d', of the resisting couple is therefore

$$d' = jd = d - kd/3 = d\,(1 - k/3) \qquad (1)$$

and we have

$$j = d'/d = 1 - k/3 \qquad (2)$$

For approx values of j, see ¶ 12.

10. Value of "k." From assumption 1, ¶ 4 we have

$$e_c/e_s = k/(1-k) \qquad (3)$$

From assumption 5, we have

$$f_c = e_c E_c; \quad f_s = e_s E_s \qquad (4)$$

Hence

$$\frac{f_c}{f_s} = \frac{e_c\,E_c}{e_s\,E_s} = \frac{k}{1-k} \cdot \frac{E_c}{E_s} = \frac{k}{n\,(1-k)} \qquad (4a)$$

For equilibrium, $C = T$; but

$$C = f_c\,b\,k\,d/2 = e_c\,E_c\,b\,k\,d/2 \qquad (5)$$

and $$T = f_s\,a_s = f_s\,p\,b\,d = e_s\,E_s\,p\,b\,d \qquad (6)$$

Hence, $k = 2\,p\,\dfrac{e_s\,E_s}{e_c\,E_c} = 2\,p\,n\,\dfrac{1-k}{k}$;

or:

$$\mathbf{k} = \sqrt{(p\,n)^2 + 2\,p\,n} - p\,n \qquad (7)$$

---

* See ¶¶ 15, 16, p 1286. ** See ¶ 13, p 1286.

† Below the neutral axis. the conc is in *tension,* but its tensile stress is neglected. See assumption 4, ¶ 4, p 1283. ‡ See ¶¶ 21, 22.

§ Figs 2 and 3 are by Prof A. W. French, A S C E, Trans, Vol 56, '06, pp 362, etc.

The dotted and solid curved lines, for conc, represent $n = 15$ and $n = 10$, respectively. The nearly straight lines, for steel, are plotted for $n = 10$, but are sufficiently approx also for $n = 15$.

18. The upper portion of **Fig 2** gives **values of**

$$\mathbf{k} = \sqrt{2\,p\,n + (p\,n)^2} - p\,n,$$

(see ¶ 10) and of

$$\mathbf{j} = 1 - k/3 = d'/d,$$

corresponding to given values of p, for $n = 10$ and $n = 15$. Note that j varies but slightly with p.

Examples.

I. Investigation.

Required the resisting moments, M_s, M_c and M.

19 a. Given a rectangular reinfd conc beam: $b = 8''$; $d = 20''$; $a_c = bd = 8 \times 20 = 160$ sq ins; $n = E_s/E_c = 15$. Let $F_s = 16{,}000$, and $F_c = 500$ lbs per sq inch, be the *max allowable* values of the unit stresses, f_s and f_c, in steel and in conc respectively; and let P be the value of p based upon these max allowable stresses

Then $F_s/F_c = 32$; $\dfrac{F_s}{nF_c} + 1 = 3.133$; and, from Eq (11), ¶ 15, we have:

$$P = \frac{0.5}{32 \times 3.133} = 0.004987,$$

as given by the intersection, in Fig 2, of radial line, for $f_s = 16{,}000$, with dotted curve for $f_c = 500$.

19 b. (Case 1) Reinforced with two round rods, ¾″ diam;

$a_s = 2 \cdot \pi\, 0.375^2 = 0.884$ sq ins;

$p = a_s/a_c = 0.884/160 = 0.005525 > P$;

$pn = 15 \times 0.0055 = 0.0825$;

$k = \sqrt{(pn)^2 + 2\,pn} - pn$

$\quad = \sqrt{0.0825^2 + 0.1650} - 0.0825 = 0.3322$;

$d' = d\,j = d\,(1 - k/3) = 20\,(1 - 0.1107) = 20 \times 0.89 = 17.8$ **ins;**

$C = F_c\, b\, k\, d/2 = 500 \times 8 \times 0.3322 \times 10 = 13{,}288$ lbs;

$M_c = C\,d' = 13{,}288 \times 17.8 = 236{,}526$ inch-lbs;

$T = F_s\, a_s = 16{,}000 \times 0.884 = 14{,}144$ lbs;

$M_s = T\,d' = 14{,}144 \times 17.8 = 251{,}763$ inch-lbs;

$M = M_c = 236{,}526$ " " .

Notice that where, as in this case and in Case 2, $\mathbf{P} < \mathbf{p}$, the mom $\mathbf{M_c}$, based upon the max allowable stress, F_c in the *conc*, is the actual mom, M Where $\mathbf{P} > \mathbf{p}$, $\mathbf{M_s}$ is the actual mom.

19 c. By Fig 2. The intersection of the vert line, on $100\,p = 0.55$ with radial line for $f_s = 16{,}000$ lbs per sq inch, gives $M_s/bd^2 = 78.7$; and $M_s = 78.7\,b\,d^2 = 78.7 \times 8 \times 20^2 = 251{,}840$ inch-lbs; but the intersection of vert line on $100\,p = 0.55$, with dotted curve ($n = 15$) for $f_c = 500$ lb per sq inch, gives $M_c/bd^2 = 74$; and $M = M_c = 74\,bd^2 = 74 \times 8 \times 20$ = 236,800 inch-lbs

19 d. (Case 2) Reinforced with 3 round rods, 1" diam;

$a_s = 3\pi\, 0.5^2 = 2.356$ sq ins;

$p = a_s/a_c = 2.356/160 = 0.01473 > P$;

$pn = 15 \times 0.01473 = 0.2209$;

$k = \sqrt{(pn)^2 + 2\,pn} - pn$

$\quad = \sqrt{0.22^2 + 0.44} - 0.22 = 0.48$;

$d' = dj = d\,(1 - k/3) = 20\,(1 - 0.16) = 20 \times 0.84 = 16.8$;

$C = F_c\, b\, k\, d/2 = 500 \times 8 \times 0.48 \times 10 = 19{,}200$ lbs;

$M_c = C\, d' = 19{,}200 \times 16.8 = 322{,}560$ inch-lbs;

$T = F_s\, a_s = 16{,}000 \times 2.356 = 37{,}696$ lbs;

$M_s = Td' = 37{,}696 \times 16.8 = 633{,}293$ inch-lbs;

$M = M_c = 322{,}560$ " ".

19 e. By Fig 2. The intersection of the vert line on $100\,p = 1.473$, with radial line for $f_s = 16{,}000$ lbs per sq inch, would give (on a sufficiently accurate diagram) $M_s/b\,d^2 = 198$, and $M_s = 198\,b\,d^2 = 198 \times 8 \times 20^2 = 633{,}600$ inch-lbs; but the intersection of vert line on $100\,p = 1.473$, with dotted curve ($n = 15$) for $f_c = 500$ lbs per sq inch, gives $M_c/b\,d^2 = 101$; and $M = M_c = 101\,b\,d^2 = 101 \times 8 \times 20^2 = 323{,}200$ inch-lbs.

19 f. It will be noticed that, in these cases, **an increase of 166.5 %.** in the amt of steel, has **increased the resisting mom** (which still depends upon the conc) **by less than 38 %:** and the steel, in Case 2, is stressed to only about 8,000 lbs per sq inch or half the max allowable stress (intersection of vert for $100\,p = 1.473$, with dotted curve for $f_c = 500$, is nearly intersected by radial line for $f_s = 8{,}000$). See ¶ 13.

19 g. In both cases, (1) and (2), the intersection of radial line for $f_s = F_s = 16{,}000$, with dotted curve for $f_c = F_c = 500$, would give (on a sufficiently accurate diagram) $p = P = 0.004987$; $M/bd^2 = 71.5$, and $M = 71.5\,bd^2 = 228{,}800$ inch-lbs, the actual mom, for the given b and d, in the **ideal case** where f_s and f_c = respectively F_s and F_c = 16,000 and 500.

II. Design.

20 a. Conversely, given the bending moment, 236,500 inch-lbs; $F_s = 16{,}000$; $F_c = 500$ lbs per sq inch; whence $P = 0.004987$, as before. **Required b and d.**

Let K and J = the values of k and of j respectively, corresponding tc $f_s = F_s$ and $f_c = F_c$.

Here we have

$Pn = 15 \times 0.004987 = 0.075$;

$K = \sqrt{(Pn)^2 + 2\,Pn} - Pn$

$\quad = \sqrt{0.075^2 + 0.150} - 0.075 = 0.3193$;

$J = 1 - K/3 = 1 - 0.1064 = 0.8936$;

$$bd^2 = \frac{M}{F_s PJ} = \frac{2\,M}{F_c KJ} = \frac{2 \times 236{,}500}{500 \times 0.3193 \times 0.8936} = 3315.$$

20 b. An infinite number of section areas, bd, **giving the same resisting moment,** M, **may be found from** bd^2.

20 c. Thus, in the example of ¶ 20 a, with $bd^2 = 3315$, we may have

b	d^2	d	
6	552	23.5	
8	414	20.3	
10	331	18.2	etc, etc.

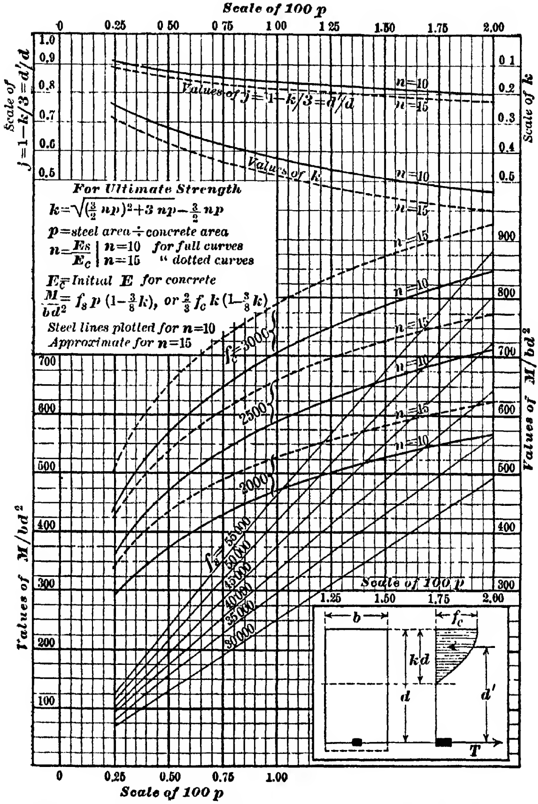

Fig 3. For Ultimate Stresses. (For allowable stresses, see Fig 2.)

$$\mathbf{k} = \sqrt{\left(\frac{3}{2}pn\right)^2 + 3pn} - \frac{3}{2}pn, \qquad \mathbf{j} = d'/d$$

$\mathbf{f_s}$ = unit stress in steel, $\mathbf{f_c}$ = unit stress in conc at top of beam

$\mathbf{p}$ = a_s/a_c = ratio of steel area to conc area,

$\mathbf{M_s}$, $\mathbf{M_c}$ = resistg mom, based upon max allowed value of f_s, f_c resp,

$\mathbf{M}$ = resistg mom, actual.

$$\frac{M}{bd^2} = f_s p\left(1 - \frac{3}{8}k\right) \quad \text{or} \quad \frac{2}{3} f_c k\left(1 - \frac{3}{8}k\right).$$

$n = E_s/E_c$. **Solid curves** represent n = 10; **dotted curves,** n = 15. **Steel lines** for n = 10; approx for n = 15. E_c = *initial* E for conc

20 d. It can be shown (T & M, pp 175–6) that, with given M, given unit stresses, and given unit prices, the **cost** of a reinfd conc beam, per unit of length, **varies** inversely as d, directly as $\sqrt{b}$, and directly as $\sqrt[3]{b/d}$. Hence, for a given bd, the deeper the beam, the less is the cost; but practical considerations (such as practical limits to reduction of b, requirements as to head room, etc) often limit the extent to which this economy can be carried in practice.

21. Within the limit of allowable working stresses. Fig 2, the stresses and deformations, in the several fibers, are taken (assumption 1, ¶ 4) as proportional to the dists of the fibers from the neutral axis, as represented by the shaded triangle in the small figure above the diagrams (said triangle representing approx the lower portion of the parabolic area shown in Fig 3); and we have, Eq (7), ¶ 10,

$$\mathbf{k} = \sqrt{(pn)^2 + 2\,pn} - pn.$$

22. For stresses exceeding the allowable workg stresses, up to the ult, Fig 3, assumption 1 is inadmissible, we must employ the entire parabolic area, its vertex corresponding with the ult comp strgth of the conc; and we have

$$\mathbf{k} = \sqrt{(3\,p\,n\,/\,2)^2 + 3\,p\,n} - 3\,p\,n\,/\,2 \qquad (14)$$

Fig 3 gives values of j, k and $M/b\,d^2$, for ult values of f_s and f_c.

23. Note that, for steel stresses, f_s, not exceeding the usual elastic limit, and with f_c ultimate $\not<$ 2000 lbs per sq inch, the ult resistg **mom increases directly with the amount of reinfmt** until this reaches 2 % or over. Thus, Fig 3, with f_s = 30,000 lbs per sq inch, f_c ult $\not<$ 2000, and p = 0 to 2 %, we have M/bd^2 = approx 25,000 p.

Tee Sections.

24. Tee sections. Fig 4. b = flange width; b' = stem width; t = flange thickness; d = depth from top of flange to cen of steel; $k\,d$ = depth of neut axis; $d' = j\,d$ = leverage of T and C

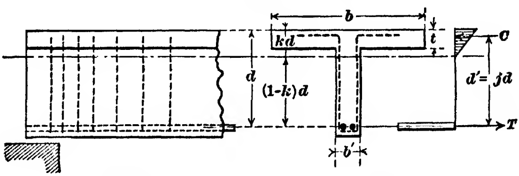

Fig 4. Reinforced Tee Section. Theory.

25. When the tops of rectangular beams are connected by slabs, the whole being placed at one time and properly bonded, all or a part of the slab may be considered as a **compression flange,** in some respects similar to those, composed of angles and plates, of steel plate girders.

26. The **width of slab,** b, Fig 4, which acts as flange, is sometimes taken as the distance between beams, but should not exceed ⅓ of the span of the beams. See Specifications, ¶¶ 168–170.

27. Exact analysis of such a section is hardly possible, but it is believed that the following **method** is reasonable and safe.

28. Determine the ratio, $p = a_s/a_c$, of steel area to conc area as tho the beam were rectangular, with depth = d, and width = the *flange* width, b. With this value of p, determine the position of the neutral axis. If this falls within the slab or just at its lower side, the resisting moment is found exactly as with any rectangular section. See Case 1, ¶ 19.

29. If the neutral axis falls below the bottom of the slab, the position of the neutral axis will not be exactly given by the equation for rectangular beams; but the difference will not be important.

30. The resisting moment is Cd' or Td', whichever is the less.

31. Examples.

(1) **Neutral axis within the slab.**

Let $b = 60$ ins; $b' = 8$ ins; $d = 20$ ins; $t = 5$ ins; max allowable unit stresses, $F_c = 500$, $F_s = 16{,}000$ lbs per sq in; $E_c = 3{,}000{,}000$; $E_s = 30{,}000{,}000$; $n = 10$. Let there be 3 round steel rods, diam = 1 inch.

Then

$$p = \frac{3 \times 0.785}{60 \times 20} = 0.002;$$

$$k = \sqrt{(pn)^2 + 2\,p\,n} - p\,n$$

$$= \sqrt{(10 \times 0.002)^2 + 2 \times 10 \times 0.002} - 10 \times 0.002 = 0.18;$$

$$k\,d = 0.18 \times 20 = 3.6 \text{ ins};$$

$$C = F_c\,b\,k\,d/2 = 500 \times 60 \times 0.18 \times 20/2 = 54{,}000 \text{ lbs};$$

$$T = 3 \times 0.785\,F_s = \text{say } 37{,}650 \text{ lbs}.$$

Using the smaller value (that for the steel) we have:

$$M = T\,d' = T\,(d - d\,k/3) = 37{,}650\,(20 - 3.6/3) = 707{,}000 \text{ inch-lbs.}$$

(2) **Neutral axis below the slab.**

Let $b = 60$ ins; $b' = 10$ ins; $d = 30$ ins; $t = 4$ ins; F_c, F_s, E_c, E_s and n as in Example (1); 6 round steel rods, diam = 1 inch. Then

$$p = \frac{6 \times 0.785}{60 \times 30} = 0.0026, \text{ and } k = 0.2;\ k\,d = 0.2 \times 30 = 6.$$

32. Since the comp unit stress, in the outer fibers of conc, is assumed to be $F_c = 500$ lbs per sq inch, the stress, at the lower side of the slab, is $500\,(k\,d - t)/k\,d = 500 \times 2/6 = 167$; and the **average stress, in the slab,** is $\frac{500 + 167}{2} = 333$ lbs per sq in.

33. The 2 inches of stem, which lie between the neutral axis and the lower side of the slab, exert some comp resistance, but this is neglected, with a small error on the safe side.

34. The **position of the center of gravity** of the compressive forces in the slab may be found as for a trapezoid; but it is usual, safe, and sufficiently approximate, to assume that it is at the cen of the slab, or, in this example, at a distance of $d - t/2 = 30 - 2 = 28$ ins above the cen of the steel. The mom of these forces is then $M_c = 333 \times 60 \times 4 \times 28 = 2{,}238{,}000$ inch-lbs; but the moment of the tensile resistance of the steel is only $M_s = 6 \times 0.785 \times 16{,}000 \times 28 = 2{,}110{,}000$ inch-lbs; and this mom, being the less of the two, is to be taken as the actual mom, M.

Shear.

35. Shear. In addition to the hor stresses, resisted by compression in the conc and by tension in the longitudinal steel reinfmt, the vertical shearing stresses require attention in relatively deep beams under heavy loads.

36. For the total shear, V, in any vert section, distant x from a support, we have:

$$V = R - W \quad\text{...}(15)$$

where R = upward reaction at the support;
W = the total of any loads in the distance, x.

37. The vert shear is sometimes provided for by using a large safety factor with the ult shearing strgth of conc, which is usually taken at from 500 to 800 lbs per sq inch, while the working shearing stress is often restricted to from 30 to 50 lbs per sq inch. But see Stirrups, ¶¶ 38, etc.

Shear Reinforcement. Stirrups.

38. Shear Reinforcement. Where the loading produces a shearing stress exceeding the limit assumed for plain conc, the beam is often reinfd by vert **stirrups,** which consist of rods, bent into the shape of a letter U, and passing under the hor bars and up to near the top of the beam; or, in the case of Tee beams (Fig 4), into the slab.

39. The distance between stirrups is sometimes made such that, within a hor length = d', there shall be an aggregate sectional area of vert steel bars sufficient to carry the vert shear by means of the permissible unit tension in the steel.

40. Example.

Consider the T beam of example (1) ¶ 31, Fig 4; $b' = 8$ ins; $b = 60$ ins; $d = 20$ ins; $k = 0.18$; $d' = 20 - k\,d/3 = 20 - 1.2 = 18.8$; safe mom of resistce, $M = 707{,}000$ inch-lbs. Let span $L = 20$ ft $= 240$ ins. Then, for a uniform load, we have $W = 8\,M/L = 8 \times 707{,}000/240 = 23{,}600$ lbs.

Shear at ends $= W/2 = 11{,}800$ lbs.

With safe unit shearing stress = 50 lbs per sq inch, we have safe shear resistance of plain conc in section $= 50\,b'\,d' = 50 \times 8 \times 18.8 = 7{,}500$ lbs

Under uniform load, this shear occurs at a dist, from the ends,

$$= \frac{(11{,}800 - 7{,}500)\,L}{2 \times 11{,}800} = 3.65 \text{ ft.}$$

From this point to the center of the span, the conc is able to care for the shear, and no stirrups are there reqd. But see ¶¶ 41, 45.

Between this point and each support, let the stirrups be of $^3/_8$ inch round steel; aggregate cross section area of the two limbs of each stirrup = 0.22 sq inch.

Allowing 16,000 lbs per sq in, one stirrup will sustain $16{,}000 \times 0.22 = 3{,}520$ lbs.

The total shear, 11,800 lbs, at the support, divided by 3520, gives 3.3 as the **number of stirrups** required, in 18.8 ins of length of beam; or the **spacing, next to the ends,** should be $\frac{18.8}{3.3} = 5.5$ ins.

Let the load, W, = 23,600 lbs, be uniformly distributed. Then, at a point 3 ft from the end, $V = \frac{10 - 3}{10} \times 11{,}800 = 8260$ lbs; $8260/3520 = 2.35$; and **stirrup spacing** $= 18.8/2.35 = 8$ ins.

41. The **spacing** may be made to **vary uniformly** betw these limits; and it would be well for the vert reinft to extend beyond the theoretical stopping point (3.6 ft from end, see ¶ 40), by one or two stirrups spaced a foot apart. See ¶ 45.

42. Let

A = aggregate vert cross sec area of hor rods, sq ins;
L = span, ft;
z = dist from end of beam to stirrup, ft;
S = aggregate cross section **area reqd in the 2 limbs of the stirrup,** sq ins.

Then, when the stirrups are 1 ft apart,

$$S = \frac{4\,A}{L}\left(1 - \frac{2\,z + 1}{L}\right) \quad \text{...(16)}$$

(J. W Schaub, E N, '03/Apr/16, p 348.)

43. In general, spacing betw stirrups $\ngtr d'$.

44. The conc, in each sec, has to act as a connecting medium between the hor and the vert reinft. It is also subjected to comp forces, in transferring the shear from one stirrup to the next. The action here is complex, and an **ample safety factor should be used.**

45. In order to provide against excessive loadings, which may come temporarily upon the beams during construction it is advisable to use stirrups, even where not actually required by the shearing stresses determined theoretically as above for the completed structure in use. The stirrups being light, the cost of using them is principally for labor; so that if *any* are reqd, it is well to be liberal with them. See ¶ 41.

Unit Shear.

46. Unit shear, v. In any hor section of a beam, Fig 5, under uniform or central loading, the hor tensile or comp stresses increase from the ends, where they are zero, toward the middle of the beam, where they are a max. Hence, of any two vert plane secs, 1 and 2, the section, 2, nearer the cen of the beam, will have the greater hor stresses, s.

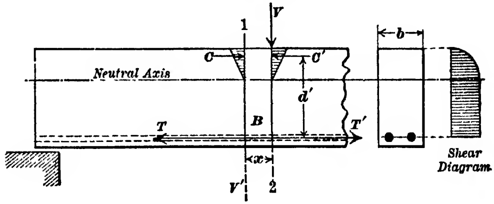

Fig 5. Unit Shear.

47. Consider the forces acting upon the rectangular body, B, between the two sections, 1 and 2.

48. At the left section, 1, the vert shear, V', coming from the left support, pushes B upward; and the tension, T, of the steel pulls B horizontally toward the left; while the total comp, C, acting at the cen of the comp forces, pushes B toward the right.

49. At the right sec, 2, the vert shear, V, pushes B downward; while T' and C' are in line with T and C respectively, but opposite to them. Note that $T' > T$, and $C' > C$. Let $T' - T = t$.

50. Let there be **no load** on B. Then $V' = V$.* Since the vert forces are distant by x, their moment $= Vx = V'x$.* The mom of $T' - T$ is $(T' - T)\, d' = td'$. Hence, **for equilibrium,**

$$Vx = t\,d'; \quad \text{or} \quad t = Vx/d' \quad \text{.......... (17)}$$

51. In a reinfd conc beam, Fig 5, we neglect the tensile strgth of the conc. Hence, the diff, $T' - T = t$, of tension, between secs 2 and 1, must be transmitted, from the steel to the neut axis, by a total shear, $= t$, uniform* in each hor sec; and, since the hor sec of the body, B, is $b\,x$, we have, for the **unit shear:**

$$v = t/b\,x = V\,x/d'\,b\,x = V/b\,d' = V'/b\,d'^{*} \quad \text{.......... (18)}$$

Diagonal Stresses.

52. As a matter of fact, the longitudinal tensile stresses and the vert and hor shearing stresses, combine to form, and are replaced by, **diagonal stresses;** and reinfmt, against shear, is more rationally designed by determining, as nearly as may be, the directions and intensities of these resultant diagonal stresses (See ¶ 53), and so placing the reinfmt as best to resist them.

53. From "Maximum Unit Stresses in Beams," p 494 e, we have, in homogeneous beams, for **the angle**, A, betw the neutral axis and the resultant normal (tensile and comp) or "principal" stresses, s_p, at any point:

$$\tan 2A = 2\,v/s; \quad \text{.......... (19)}$$

and, for the **max stress,**

$$s_p = s/2 + \sqrt{(s/2)^2 + v^2}; \quad \text{.......... (20)}$$

where v = the unit vert or hor shear, and s = the unit hor tensile or comp stress, at the given point.

---

* **If there is a load,** L, upon B (as, for instance, in the case of uniform loading) we have $V' > V$, and $V' - V = L$; and there are *two* couples of vert forces, with moms, respectively: Vx and $(V' - V)\,x'$, where x' = dist from sec 1 to gravity center of L. Here we have, for sec 1, $v' = V'/b\,d'$; and, for sec 2, $v = V/b\,d'$.

54. But, neglecting the tensile strgth of the conc, we have, in beams with tension reinfmt of straight bars, and for points betw the neutral axis and the steel, $s = 0$; whence:

$$\tan 2A = \infty; \quad 2A = 90°; \quad A = 45°;$$

$$s_p = \sqrt{v^2} = v = V/bd' \quad \ldots\ldots(21)$$

55. Hence, betw the neut axis and the steel, we should provide against **tensile unit stresses,** $s_p = V/b\,d'$, acting in parallel directions forming angles of 45° with the neut axis.

56. Other things being equal. this provision is preferably made by means of **rods, placed like the diag tension members** of a Pratt bridge truss, Figs 7*b*, 8*b*, 9*b*, p 693, and forming angles of 45° with the hor.

57. Very commonly, the tension rods, at each end, in a hor dist about equal the depth of the beam, are bent upward to form an angle of 45° or thereabouts with the axis of the beams.

Adhesion. See p 1279.

58. Unit of adhesion. Let

x = a given portion of the length of the beam;
t = $T' - T$ = the increase, in total tension, T, in the steel, in the lgth, x;
V = the total vert shear in the cross section;
d' = the dist betw T and the cen of comp of the conc;
U = t/x = the bond stress, per unit of x;
m = the number of rods;
a = the circumference of one rod
= the circumferential contact area of one rod, per unit of x;
u = $U/m\,a$ = the bond stress, per unit of a.

Then (see ¶ 50), $t\,d' = V\,x$; $t = V\,x/d'$; $U = t/x = V\,x/d'\,x = V/d'$; and

$$u = U/ma = V/d'\,m\,a \quad \ldots\ldots(22)$$

59. For given values of the bond stress, U, per unit of length, and of the bond stress, u, per unit of circumferential contact area, the product, $m\,a = U/u$ (= total circumferential area per unit of length) in a given case, is constant; but the cross sec area, weight and cost of the rods increase as the *square* of a. Hence, for a given total adhesion, numerous **small rods are more economical** than fewer larger rods; but there is, of course, for each case, a practical limit to this economy.

Continuous beams.

60. Floor systems are usually composed of slabs and beams continuous over supports; and, if the negative bending moments over the supports (producing *tension* at *top* of beam) are amply provided for, by reinfmt near the top, and if the supports are unyielding, or exactly equal in their yielding, advantage is usually taken of the reduction in the positive bending moms (at and near cen of span) due to continuity.

61. Where floor slabs are laid continuously over the supporting beams, it is usual to assume $WL/10 = wL^2/10$ as the max bending mom, where L = span; W = total load on span; $w = W/L$ = load per unit of L. Beams, continuous over the supports, may have a like value used in design, if the beams are amply reinfd at top and over the supports.

62. On the score of safety, it is frequently specified that beams, slabs, etc, shall be regarded as non-continuous over supports, this practice requiring us to provide, at cen of span, against greater (positive) bendg moms than if the beam were continuous over supports; but, on the other hand, few if any beams are wholly non-continuous; i e, even where the beam is supposed to be non-continuous, there are negative bendg moms over the supports, due to the width of the support and to the presence of loading upon the beam over the support. Such moms require reinfmt at top, over and near supports.

63. Hence, while it is advisable, in the case of non-continuous beams, to calculate the positive center bendg mom upon the assumption of absolute non-continuity, the condition of even non-continuous beams, over their supports, should be carefully investigated, and provision made for any negative moms there found.

64. Double Reinforcement. The necessity, under certain conditions, of reinfg against negative, as well as against positive moments (¶ 62) gives rise to cases (Fig 6) where reinfmt appears near both top and bottom of the section. For brevity, that on the side which, under positive mom, is under compression, will be called "compression reinft."

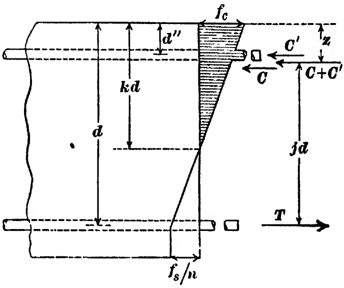

Fig 6. Double Reinforcement.

65. In addition to the symbols of ¶ 5, p 1283, let

a_s' = cross section area of comp reinft;

$p' = a_s'/a_c = a_s'/b\,d$ = steel ratio for comp reinft;

f_s' = unit stress in comp reinft;

C' = total stress " " " ;

d'' = dist from " " to nearest face of beam;

z = " " comp resultant, $C + C'$, to nearest face of beam.

66. Then, (neglecting the slight diminution of a_c by the presence of a_s') for **position of neutral axis:**

$$k = \sqrt{2\,n\,(p + p'\,d''/d) + n^2\,(p + p')^2} - n\,(p + p'); \qquad (24)$$

for position of compression resultant:

$$z = \frac{k^3\,d/3 + 2\,p'\,n\,d''\,(k - d''/d)}{k^2 + 2\,p'\,n\,(k - d''/d)}; \qquad (25)$$

for arm of resisting couple:

$$j\,d = d - z; \qquad (26)$$

for fiber stresses:

$$f_c = \frac{6\,M\,k/b\,d^2}{3\,k^2 - k^3 + 6\,p'\,n\,(k - d''/d)\,(1 - d''/d)} \qquad (27)$$

$$f_s = M/p\,j\,b\,d^2 = n\,f_c\,(1 - k)/k \qquad (28)$$

$$f_s' = n\,f_c\,(k - d''/d)/k \qquad (29)$$

METHODS OF REINFORCEMENT.

1. The **commonly accepted theory** of reinfd conc beams requires longitudinal tension reinfmt near the bottom* of the beam, and diag tension reinfmt at 45°, not only betw the hor reinfmt and the neutral axis, but extending upward into the region of compression, in order to take advantage of the superior adhesion due to the compression there. It also requires, usually, tension reinfmt near the top,* at points over or near the supports.

See ¶¶ 60, etc, p 1294.

*The terms "bottom" and "top" are here used as referring to a beam supported at the ends, and loaded on top, where the major portion of the bottom is in tension. In a cantilever, of course, this is reversed.

54. But, neglecting the tensile strgth of the conc, we have, in beams with tension reinfmt of straight bars, and for points betw the neutral axis and the steel, $s = 0$; whence:

$$\tan 2A = \infty; \quad 2A = 90°; \quad A = 45°;$$

$$s_p = \sqrt{v^2} = v = V/b\,d' \quad\text{.......... (21)}$$

55. Hence, betw the neut axis and the steel, we should provide against **tensile unit stresses,** $s_p = V/b\,d'$, acting in parallel directions forming angles of 45° with the neut axis.

56. Other things being equal. this provision is preferably made by means of **rods, placed like the diag tension members** of a Pratt bridge truss, Figs 7*b*, 8*b*, 9*b*, p 693, and forming angles of 45° with the hor.

57. Very commonly, the tension rods, at each end, in a hor dist about equal the depth of the beam, are bent upward to form an angle of 45° or thereabouts with the axis of the beams.

Adhesion. See p 1279.

58. Unit of adhesion. Let

x = a given portion of the length of the beam;

t = $T' - T$ = the increase, in total tension, T, in the steel, in the lgth, x;

V = the total vert shear in the cross section;

d' = the dist betw T and the cen of comp of the conc;

U = t/x = the bond stress, per unit of x;

m = the number of rods;

a = the circumference of one rod

= the circumferential contact area of one rod, per unit of x;

u = $U/m\,a$ = the bond stress, per unit of a.

Then (see ¶ 50), $t\,d' = V\,x$; $t = V\,x/d'$; $U = t/x = V\,x/d'\,x = V/d'$; and

$$u = U/m\,a = V/d'\,m\,a \quad\text{.......... (22)}$$

59. For given values of the bond stress, U, per unit of length, and of the bond stress, u, per unit of circumferential contact area, the product, $m\,a = U/u$ (= total circumferential area per unit of length) in a given case, is constant; but the cross sec area, weight and cost of the rods increase as the *square* of a. Hence, for a given total adhesion, numerous **small rods are more economical** than fewer larger rods; but there is, of course, for each case, a practical limit to this economy.

Continuous beams.

60. Floor systems are usually composed of slabs and beams continuous over supports; and, if the negative bending moments over the supports (producing *tension* at *top* of beam) are amply provided for, by reinfmt near the top, and if the supports are unyielding, or exactly equal in their yielding, advantage is usually taken of the reduction in the positive bending moms (at and near cen of span) due to continuity.

61. Where floor slabs are laid continuously over the supporting beams, it is usual to assume $WL/10 = wL^2/10$ as the max bending mom, where L = span; W = total load on span; $w = W/L$ = load per unit of L. Beams, continuous over the supports, may have a like value used in design, if the beams are amply reinfd at top and over the supports.

62. On the score of safety, it is frequently specified that beams, slabs, etc, shall be regarded as non-continuous over supports, this practice requiring us to provide, at cen of span, against greater (positive) bendg moms than if the beam were continuous over supports; but, on the other hand, few if any beams are wholly non-continuous; i e, even where the beam is supposed to be non-continuous, there are negative bendg moms over the supports, due to the width of the support and to the presence of loading upon the beam over the support. Such moms require reinfmt at top, over and near supports.

63. Hence, while it is advisable, in the case of non-continuous beams, to calculate the positive center bendg mom upon the assumption of absolute non-continuity, the condition of even non-continuous beams, over their supports, should be carefully investigated, and provision made for any negative moms there found.

[illegible]

elastic limit. by permitting the use [illegible] higher unit stresses, renders elongation [illegible] panying cracking of the conc, and lateral c[illegible] of the steel, which **endangers the adhesion.** On this account, it is sometimes specified that, where the elastic limit exceeds a certain min (say 40,000 lbs/sq inch) deformed bars, ¶¶ 15 etc, shall be used. At 30,000 lbs/sq inch, steel stretches about 0.10 per cent; at 50,000 lbs/sq inch, about 0.17 per cent.

Cold working raises the ultimate strength and the elastic limit, but slightly lowers the elastic modulus; see Fig 1, representing tests at Watertown Arsenal (Tests of Metals, 1904, p 397) on plain and cold-twisted steel bars, ¾ inch square. Gaged lengths, 10 inches. The twisted bar had 1 twist in 8 inches. Similar results were shown in tests made at Watertown Arsenal, July 12, 1902, and published by Ransome Concrete Co, See ¶ 21.

Square bars, of interior steel, are twisted hot, and are more brittle.

10. Plain round steel bars are very generally used for reinforcement in America, and still more generally in Europe. **Square bars** also are used, but are less conveniently handled. **Flat bars** have been found deficient in adhesion.

11. In order **to increase the resistance of plain bars** to being pulled thru the conc, they are frequently bent up at right angles (or bent over at 180° so as to form a hook) at their ends.

12. "Anchorage, furnisht by short bends at a right angle, is less effective than hooks consisting of turns at 180°." **J. C.**

13. For the same purpose, (¶ 11), the bars may be threaded at their ends, and provided with steel **anchor plates,** secured by nuts. Such plates should be large enough and thick enough to withstand pulls due to the full tensile strength of the rods. In designing such plates, Prof. L. J. Johnson assumes a crushing strgth, in the conc, of 900 lbs/sq inch, and a fiber stress in the anchor plate, of 25,000 lbs/sq inch. Several rods, side by side, pass thru a common large plate at each end, which serves, also, to hold the rods in their relative positions while the conc is being placed. Nuts, on the inside, holding the anchor plate to a firm bearing against the outside nuts, are an important provision. Room, for such plates, is usually found in a wall or column, or over a knee-bracket, etc. Otherwise, in order to give room for the anchor plate, the beam may be deepened locally, or the rods bent up, near their ends. When bent up, the rod exerts an upwd pres upon the conc, near the bend. This increases the friction, in the bent portion, and thus reduces the pull transmitted to the anchor plate.

14. "Adequate bond strgth, thruout the length of a bar, is preferable to end anchorage." **J. C.**

15. Also for the purpose of increasing adhesion (or rather to substitute, for it, a "mechanical bond") **"deformed bars,"** of various shapes are used.

16. The **principal claim,** in favor of deformed bars, is that the "mechanical bond," which they offer, is the sole reliance of the reinfmt, after its adhesion proper has been destroyed, as by a stress exceeding the adhesion, by infiltration of water, by concussion either during or after construction, or by constant and rapid alternations or reversals of loading, in service. Vert rods especially, during construction, are liable to accidental blows upon their projecting upper ends; and such blows may affect the adhesion of the portions already imbedded in conc.

17. On the other hand, it is pointed out that innumerable structures, with plain bars, have satisfactorily withstood, for years, service involving such vibration; and it is claimed that whatever advantage arises from deformation is more than offset by the slight increase of cost. Plain bars are of course free from patent claims, and they are at all times readily obtainable in the general metal market.

18. The projections, on the surfs of some deformed bars, may injure the conc covering unless this is of considerable thickness.

19. In studying comparative tests of plain and deformed bars, attention should be given to the richness of the conc mixture. Unless this is sufficiently rich to insure the **complete covering of each bar** with cem over its entire surf, the adhesion proper will not be fairly developed, and the pulling test will exhibit chiefly the diff in "mechanical bond," in which, of course, the deformed bars are superior.

20. "Deformed bars offer a suitable means for supplying high bond resistance." **J. C.**

The following deformed rods, Figs 2, are in more or less general use:

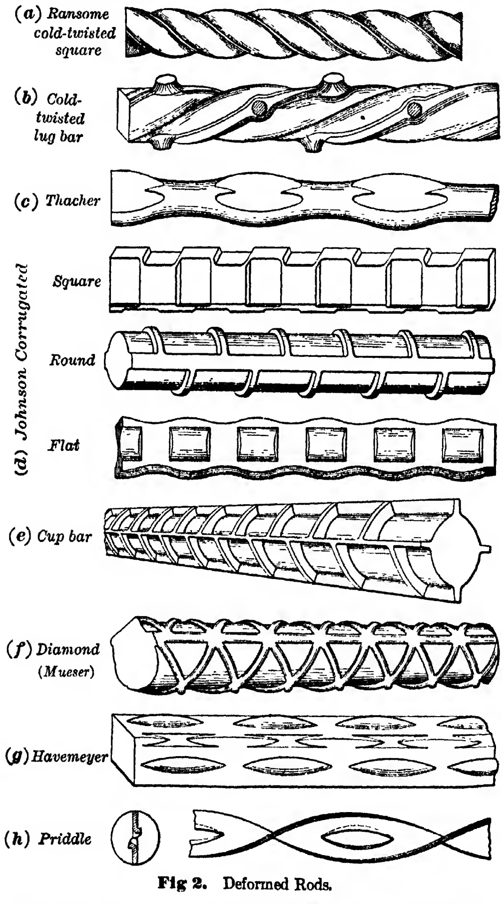

Fig 2. Deformed Rods.

21. Ransome. (*a*) Square steel rods, twisted cold. Twisted either at mill, or (conveniently and inexpensively) on the work.

22. Cold-twisted lug-bar. (*b*) Square bar, with angles rounded, to prevent the starting of cracks in the conc, twisted cold. The lugs are designed to resist any tendency of the bar to untwist under tension. For effect of cold working, see ¶ 9, p 1297.

23. Thacher. (*c*) Round rods, deformed by flattening at short intervals. Cross sec area practically constant. Changes in shape made by means of gradual curves.

24. Corrugated bars; (*d*) ordinarily of steel with yield point 50,000 lbs/sq inch or over. Square, round and flat.

25. Cup bars, (*e*).

26. Diamond bar. (*f*) Rolled round, with two spiral projecting ribs of equal pitch and in opp directions (dividing the surface into four rows of diamond-shaped recesses) and two opp longitudinal ribs, at the points where the upper and lower rolls meet in manufacture. Cross-section area and weight = those of plain square bars of like denomination. Claims: uniform cross section area, uniform elongation, uniform distribution of bond; projecting ribs aid in resisting tension; edges rounded; no tendency to untwist under tension.

27. Havemeyer bar. (*g*) Square, with rounded corners and projections.

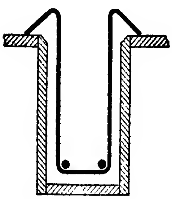
28. Priddle Internal-bond Bar. (*h*) Flat bar, perforated and twisted, and the slit flanged, as shown. Small sizes worked cold; larger sizes, hot, A web may be formed by passing smaller bars, of same or other pattern, thru the slits.

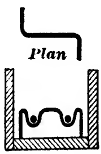
29. The monolith bar consists of a hor tension member with separate diag links. In section, the hor member resembles a heavy rail with two heads instead of head and flange. Each link is a bar of round steel, bent over at top and thus forming two parallel diag legs, which, at bottom, are bent hor, and their hor portions, one on each side of the hor member, are gripped between its heads, which are swedged in, at those points, for the purpose.

Supports.

30. It is of course of the first importance that the longitudinal **reinforcing bars** be placed and kept **in their proper positions.** If, as finally located, they are too high, their resisting leverage, d', and the resistg moment of the beam, are diminished. If they are too low, they have an insufficient protective depth of conc below them. Various devices are in use for holding the bars in position.

31. Stirrups, Fig 3, act as hangers for the main rods.





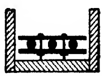


Fig 6.

Fig 3. Fig 4. Fig 5.

Supports for Reinforcing Bars.

32. Light rods are sometimes held by **wire supports,** Fig 4, or by **conc blocks,** about 1.2 or 2 ins thick, Fig 5.

33. Heavier rods may be supported by **clamps,** Fig 6, made of pieces of ¾″ or 1″ channel iron, held together by round-headed stove bolts, ¼″ or ⅜″ diam, placed in the forms, and 6 or 8 ft apart.

"Web" Reinforcement.

34. Web reinforcement is used in broad and shallow slabs, in thin walls, in sewers and conduits, in columns, etc.

35. The simplest form consists of **rods, placed at right angles,** and wired or welded together at their intersections. The heavier or main rods are of course so placed as to take the greater stresses. The transverse rods hold the main rods in position during construction, and afterward distribute their tension across the intervening conc. They thus offer a mechanical bond. The mesh must be large enough to pass the particles of the agg used in making the conc.

36. Jean Monier, of Paris, used such webbing in the reinforcement of arches.

37. Expanded metal. Fig 7. Sheet steel, slitted and opened out into diamond-shaped panels. In sheets, 12 to 72 ins wide, 8 to 12 ft long; mesh from ½" to 6"; metal, Stubs gage, No. 18 to No. 4.

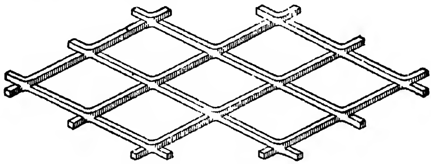

Fig 7. Expanded Metal.

38. When slab reinforcement is furnisht in short sheets, these must **overlap** sufficiently to transmit the tension from one sheet to the next. The lapping uses about 10 % of the area of the metal.

39. Clinton wire lath, in rolls of 100 or 200 ft or more, of drawn steel wires, crossing at right angles, 2½ inch mesh, electrically welded and reinfd by longitudinal reinfg warp strands, 6 ins apart, and made up each of two wires cross-looped and twisted over each crossing strand; and, when desired, by transverse V-shaped stiffeners of No. 24 gage steel, fastened to the wires at intervals of about 8 ins. Furnisht plain, japanned or galvd, in 36 inch width.

40. Clinton welded wire; No 3 to No. 10 drawn steel wire, plain or galvd; mesh, 3 × 8, 2 × 12, 3 × 12, 4 × 12 ins.

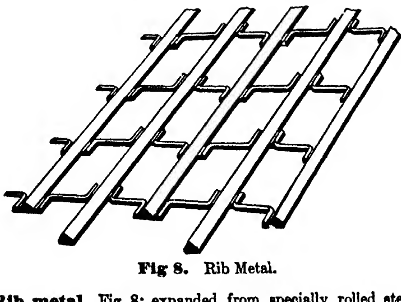

Fig 8. Rib Metal.

41. Rib metal, Fig 8; expanded from specially rolled steel plates, ribbed longitudinally. Mesh varying, by single inches, from 2 to 8 ins. Sheets up to 16 ft long

42. Rib lath, Fig 9.

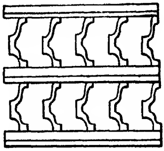

Fig 9. Rib-Lath.

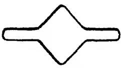
Trussed Reinforcement.

43. In general, trussed reinforcement is slightly more expensive than plain bar reinfmt; and, if shipped in rigid built-up units, it incurs higher freight charges and is more liable to damage en route; but it has the great advantage of holding the bars in position while the conc is being placed, and of obviating the omission or misplacement of stirrups, etc, either by accident or by design. The trusses may be made up of either plain or deformed bars. They should be provided with means for connecting them, over the supports.

44. In the **Kahn trussed bar,** Fig 10, the projecting side fins are slit away, in places, from the central portion, and bent up, as shown. The same bar, inverted, is used over the supports.



Cross sec at cen.

Fig 10. Kahn Bar.

45. Fig 11 shows the **collapsible Economy Unit frame.**

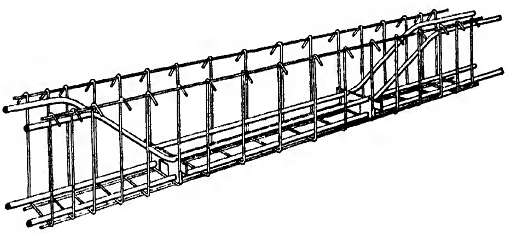


Fig 11. "Economy" Collapsible Truss.

Reinforcement with Structural Shapes.

46. The Melan system, invented by Joseph Melan, of Austria-Hungary, in 1892, and patented in the United States in 1893, comprises a concrete arch in which iron or steel beams are embedded. For small spans, the beams are usually rolled I-beams; while, for spans of considerable length, they usually consist of four angles latticed.

47. Where a structural shape, of considerable size, is imbedded in conc, to form a beam, so that **the steel predominates** and furnishes most of the strgth reqd, **the conc acts chiefly as a protecting cover** for the steel; and the case is hardly one of reinfmt properly so called.

48. It is **difficult to secure perfect filling,** with conc, of the spaces under the flanges of rolled or built-up shapes. In such cases, each day's work should be stopped either well above or well below the flange. Otherwise, shrinkage, under the flanges, will aggravate the difficulty.

Column Reinforcement.

49. Columns are reinfd by means of **vertical rods,** placed near the circumf and usually wired together at intervals, **or by circumferential** (hooped or spiral) **wrapping,** or both.

See Reinfd conc cols, pp 1280, etc.

50. In tall buildings, the column rods are often **faced at the ends** to give good bearing, and connected by loose sleeves, which keep the ends in proper contact; and an iron or steel plate is placed under the feet of the rods in the footing, to distribute the load more evenly over the conc of the foundation.

51. In Mr. C. A. P. Turner's **mushroom system** of columns and floors, the cols are splayed, at top, to increase their bearing area, and the floor reinfmt consists essentially of straight members (hor or nearly so) radiating from the cols, and joined, at intervals, by circular or polygonal members, which cross the radial members generally at right angles. Beams and ribs are dispensed with, and the floor is of uniform thickness. See E N, '09, Feb 18, p 178.

EXPERIMENT AND PRACTICE.

Directory of Selected Results, pp 1308, etc.

Words in **bold-face** type, preceding a semicolon, refer to one of two related matters; words in plain type, following the semicolon, to the other one. Numerals and letters refer to the records of experiment, etc.

Example. Under **SAND** (below), "**Sand, character;** density of mortar, 8*c*, *e*, 9*d*, 86*c*" refers to Experiments 8*c*, etc, which give information respecting the effect of (1) character of sand upon (2) density of mortar. Conversely, on p 1304, we find "**Mortar, density of —;** character of sand, 8*c*, *e*, 9*d*, 86*c*."

Selected Results.

See Directory, pp 1303, etc.

Order of arrangement.

The features entering into the manufacture and behavior of concrete are so numerous, and in the reports of experiments, etc, they are unavoidably so interlaced, that it has been found impracticable to group the several items in the body of the text in satisfactory order below.

Most of our "selected results" are therefore here placed approx in the order of their dates of publication, and furnisht with a directory, pp 1303, etc, by means of which any particular subject may be promptly found. The directory is arranged rationally (i e, not alphabetically), and, as far as practicable, in the order followed in the text (pp 1222–1250, 1252–1302), referring to cement, sand, mortar, aggregate and concrete, plain and reinforced. The items, covered by any one publisht statement, are given a common number, and, under this common number, the several paragraphs are indicated by letters. These letters usually distinguish also betw the several features covered by the common number.

Thus, under Expt 8, we have a number of conclusions reached by R. Feret: under 8 *a*, conclusions respecting strength of mortar as affected by proportion of cement and fineness of sand, under 8 *c*, conclusions respecting porosity and permeability as affected by fineness of sand and richness of mortar, etc, etc.

In the directory, semicolons, in general, are used to distinguish between two different but related ideas. Thus, "**Strength:** fineness of sand" and "**Sand, fineness of** —: strength," refer to items giving information respecting the effect of fineness of sand upon strength of mortar or conc.

6	Equal parts of Nos. 4 and 5, mixed	. 91¼	36.0

— 4 —

4. Eliot C. Clarke, A S C E Trans, Apr, '85, Vol 14, p 163. Expts for Boston Main Drainage Works.

Results.

4 a. Clay. The addition of not exceeding one part of clay to 2 of cem, gave a "much more **dense, plastic** and **water-tight** paste, convenient for plastering surfaces or stopping leaky joints." and, in general, had no markt effect upon the **strength** of Portland and natural cem. Mortars, made with sand containing 10% of loam, were of normal strgth at 6 and 12 mos, tho of only about half normal strgth up to 1 mo. Clay, in cem, is "an almost impalpable powder, with particles fine enough to fill the spaces between the particles of cem."

4 b. A year's saturation in **fresh or salt water,** and in contact with **oak, hard pine, white pine, spruce or ash,** did not affect the mortars.

4 c. Salt, either in the water used for mixing, or in that in which the cem is laid, retards **setting** somewhat, but has no important effect upon the **strength.**

4 d. Consistency. Excess of water retards **setting. Nat** cems need more water than **Port; fine-ground** more than coarse; **quick-setting** more than slow.

4 e. The finer the sand, the less the **strength.**

4 f. With sand, **fine-ground** cems are strongest; **coarse-ground** are strongest neat, especially with Portlands.

4 g. Port resisted **abrasion** best when mixt with 2 parts sand; nat with 1 part. Resistance diminished rapidly with slight variations from these proportions.

4 h. In setting, mortars expand ≯ 1 part in 1000.

— 7 —

7. Dr. Wilhelm Michaelis, Inst C E Procs, Vol 107, '92, pp 372, 375.

7 a. Disintegration of porous cem **in sea water** shown to be **due to** the action of sulfuric and hydrochloric (muriatic) acids, contained in the magnesium sulfates and chlorides of sea water. These acids leave the weaker base, magnesium (which is deposited as a hydrate), and combine with the lime of the cem, expanding and disintegrating the conc.

For Directory to Experiments, see pp 1303–7.

— 8 —

8. R. Feret. Annales des Ponts et Chaussées, 7e série, Tome IV, '92.

8 a. Results. Strength of mortar increases with proportion of cem, and, in general (especially at the beginning of hardening) with size of sand.

8 b. Mortars vary widely as to **porosity.** Compare 9 *d*, 9 *e*.

8 c. Porosity increases
with fineness of sand,
with richness of mortar

8 d. Permeability increases
with coarseness of sand,
with richness of mortar.

8 e. Mortars made with a mixture of **coarse and fine sands** are less porous and less permeable than others.

8 f. The **permeability** of mortars subjected to continuous percolation of fresh or sea water, **diminishes rapidly;** but, in certain cases, the mortar disintegrates or cracks.

8 g. To avoid disintegration in **sea water,** use coarse sand and plenty of cem. Mix wet.

8 h. Density of sand; moisture and tamping. Fig. 1.

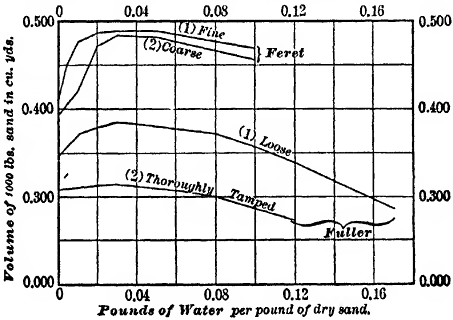

Fig 1. Moisture and Tamping.

M. Feret used (1) a very fine dune sand and (2) a coarser sea sand. Wm. B. Fuller, E N, '02, Jul 31, p 81, used a bank sand, (1) loose and (2) tamped. From these results, it appears that the addition of water affects the vol of the sand* in two opposite ways; (1) by insinuating itself betw the sand particles, thus *increasing* the vol for a given wt; (2) by decreasing the friction between the grains, allowing them more readily to take up the positions of closest contact, and thus *diminishing* the vol. When only small vols of water have been added, the first of these effects seems to prevail, the bulk increasing until the vol of water reaches from 2 to 5 % of the vol of dry sand.* With more water, the lubricating effect prevails, the vol diminishing.

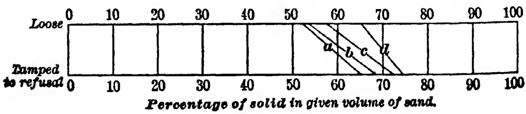

Fig 2. Compacting.

8 i. Shape of grain and tamping. Fig. 2.

* See foot-note *, p 1238.

For abbreviations, symbols and references, see p 1251.

Specimens. Four materials, as follows:
a. Granitic sand, rounded grains; *c.* Broken shells, flat grains;
b. Ground quartzite, angular grains; *d.* Residue from *b*, lamellar grains.
Each of the four materials screened to the same granulometric composition, viz: *c*, 0.5; *m*, 0.3; *f*, 0.2.† (See p 1238.)

Results. See Fig. 2.

8 j. Effect of size of grain. Fig. 3.

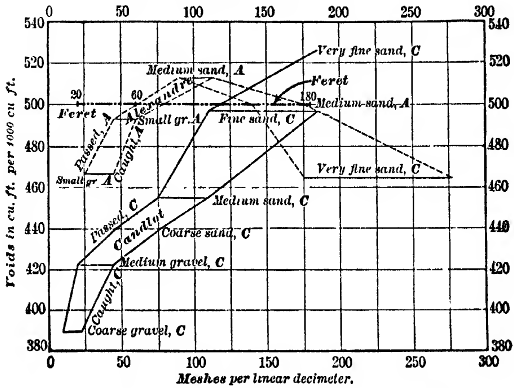

Fig 3. Size and Density. **A** = Alexandre; **C** = Candlot.

Theoretically, the density, in a sand* or gravel,* composed of grains of *uniform* size, should be independent of the *absolute* size (¶ 30, p 1241); but experimenters have obtained contradictory results, showing unimportant variations of density with size. Thus (T & T, p 170), if sand (except very fine sizes, such as pass a sieve with 74 meshes per linear inch) and broken stone, with irregular particles of approx uniform *shape*, be separated into portions containing particles of uniform *size*, these several portions will show approx equal percentages of voids. This agrees with R. Feret's experiments (T & T, pp 171 and 142), Fig 3, according to which each of the 3 sizes (coarse, medium and fine†) contained 50 % voids. M. Feret's results are represented by the hor line in Fig 3. On the other hand (Fig 3) M. Candlot (Feret, Ann des Ponts et Chaussées, 1892, 2e sem) found the voids increasing continuously, and M. Alexandre (*ibid*) found them first increasing and afterward decreasing as the size grew smaller.

8 k. Effect of sizes of grains, and shaking or tamping. Loose sand* shows densities ranging from 0.525 to 0.610, the max density occurring when 60 % of coarse sand† is mixed with 40 % of fine sand, without medium sand. In **sand shaken to refusal**, the densities range from 0.600 to 0.793, the max density occurring with a mixture of 55 % coarse with 45 % fine; no medium.

* See foot-note *, p 1238.
† Classification of sizes.

	Passed	Retained on	
c. Coarse	20	60	meshes per lineal decimeter.
m. Medium......	60	180	" " " "
f. Fine..........	180	...	" " " "

9. **Luigi Luiggi** and **Valentino Cardi,** "Esperimenti sulle Calci, etc;" Genio Civile, Rome, '93.

Porosity, permeability, etc. **Safe loads.** Twelve years' expts in connection with harbor works at Genoa, Italy.

Results.

9 a. In mortar, **voids are due** partly to air adhering to particles of sand and agg, partly to evaporation of the water used in mixing.

9 b. In mortar, **volume of voids** may vary from 12 to 46 % of vol of mortar.

9 c. Minimum voids (5 %) in conc formed with 700 lbs Port cem, 1 cu yd mixt sand, 1 ¼ cu yds small gravel.

9 d. Porosity increases
with fineness of sand;
" richness of mortar;
greatest with neat cem.
Compare 8 *c*, 8 *d*.

9 e. Permeability increases
with coarseness of sand;
" poorness of mortar;
least with neat cem.

9 f. Concrete of 1150 lbs Port cem, 1 cu yd mixt sand, 1 ¼ cu yds small gravel, carefully mixt with just enough water (about ⅛ cu yd) to work it up, was **impermeable** under 40 ft head (17.3 lbs/□").

9 g. Concrete of 700 lbs Port cem, 1 cu yd mixt sand, 1 ¼ cu yds small gravel, made into a hollow cyl with shell 2½" thick, was **impermeable** under 13 ft head (5.64 lbs/□") and barely permeable under 27 ft (11.7 lbs/□"). Similar cyls, of same mixture, **without the gravel,** leaked somewhat under 13 ft and easily under 27 ft.

9 h. Safe load in compression. In the floors of the graving docks, 1 : 2 : 3 conc of Port cem, sand and small gravel, safely carries 107 lbs/□" ; safety factor, 15.

1	3	6	91	3	788

— 16 —

16. Considère, Génie Civil, '99.

16 a. Ductility.

Specimens and results;

Conc cantilevers, 1 : 3, 6 cm sq, 60 cm long, tension side reinfd by 3 round iron bars 4¼ mm diam

Treatment. Loading such that bendg mom was the same for all cross secs. In one of the prisms, load increased until unit stretch = 0.002. Then loads, = 44 to 71 % of this original load, were applied 139,000 times; stress returning to 0 each time.

Results. Unit stretches, 0.000545 to 0.00125; strgth but little reduced. Similar tests of unreinfd specimens gave unit stretch, at rupture, only 0.0001 to 0.0002; the **reinforcement** apparently enabling the conc to endure far greater deformation than when not reinfd. But see Expts 36, 38.

For abbreviations, symbols and references, see p 1251.

— 17 —

17. C. E. Fowler, A S C E, Trans, '99, Vol 42, p 117.

17 a. Results. Proportions, assuming that
1 bbl Portland cem = 3.8 cu ft.
34 cu yds concrete = abt 27 cu yds after ramming.

Those concs, for which the vols of stone appear in bold-face type (as **1.00**), have their voids filled or more than filled; while, in those printed in plain type (as 1.04), the voids are not filled and the conc is porous and deficient in strgth.

	Quantities in 1 cu. yard of concrete:			
Proportions	Cement, Barrels	Sand, cu yds	Stone with 40 % voids, cu yds	Stone with 50 % voids, cu yds
1 : 2 : 3	1.77	0.51	**0.87**	1.05
1 : 2 : 4	1.59	0.47	**0.95**	1.15
1 : 2 : 5	1.39	0.42	1.04	1.26
1 : 3 : 4	1.30	0.57	**0.83**	**1.00**
1 : 3 : 5	1.16	0.52	**0.92**	1.11
1 : 3 : 6	1.04	0.48	**1.00**	1.20
1 : 4 : 6	1.00	0.55	**0.91**	1.09
1 : 4 : 7	0.92	0.51	**0.97**	1.17
1 : 4 : 8	0.83	0.47	1.03	1.25

The foregoing figures agreed well with the results of practice. The column for stone with 40 % voids closely represents broken limestone, which breaks into pieces of various sizes; while the column with 50 % voids represents trap rock, which breaks into pieces of more nearly uniform size.

21 b. Density of concrete: thoro **ramming.**

Vol of 1 : 1 mortar,	Vol of rammed conc, approx,
0.33 × vol of agg,	0.91 × vol of agg,
0.40 × " " "	0.93 × " " "

21 c. Density of aggregate; compacting. Portage stone, broken to pass a 2″ ring, and having 43.3 % voids when slightly shaken in the measure, had only 37.4 % voids, as a mean of 5 trials, after being packed in the measure with a tamping iron, used about as forcibly as in ordinary ramming of conc.

— 22 —

22. Tests of Metals, '00, pp 1109, &c. For Contractors Plant Co.

22 a. Specimens; Port cem, sand, crushed stone, 1 : 3 : 5. Stone passed thru a 2½″ ring; pieces passing a ⅛″ ring screened out.

A, hand-mixt; B and C mixt in a portable gravity mixer 8 ft long, consisting of a steel trough containing numerous rows of steel pins, staggered. Water from a spray pipe strikes the mixer about midway its length. Hence conc is mixt dry in the upper half, and wet in the lower.

Stone spread evenly on a platform in front of mixer
Sand " " " top of stone
Cem " " " " " sand.

Material then shoveled into mixer.

B. Allowed to form a cone-shaped pile, stones accumulating around edges.

C. Material, as discharged, levelled off with hoe.

12″ cubes; beams from 4″ × 6″ to 6″ × 6″ 30″ span. All, 2 days in air, 2 mos in water, 1 mo in air.

* Consistency: D = dry; P = plastic; E = excess

† Shrinkage = $\frac{100\ (A - C)}{A}$.

For Directory to Experiments, see pp 1303–7.

Atlas Port, 1 cem, 3 gravel (2 sand, 1 pebbles), 4 hard crusher run limestone; 8 cubes Louisv nat, 1 cem, 2 gravel, 3 stone.

Same as used in track elevation masonry by Chic, Mil and St P Ry.

Treatment. All the cubes made by same person in molds of 1" lumber, and left in molds until broken.

Results.

27. G. Y. Skeels, Asst City Engr, Sioux City, Iowa. E N, '02, Nov 6, p 382.

27 a. Avs of 2 and 4 briquets, 1 day in air, 14 ds in water. Port cem. Under **continuous mixing** for 8 or 10 hrs, neat cem mortar lost about ⅛ of its **tensile strength;** 1 : 2 lost about ⅙.

— 28 —

28. Thos. S. Clark, Resident Engr in Chg of Construction of Manhattan R R Power Station, New York. E N, '02, Jul 24, p 68.

28 a. Retempering; strength. Neat nat cem mortar mixed initially with 28 % water; sand nat cem mortar with 14 %. Retempered an hour after mixing, "enough water being added, as in practice, to bring the mass back to its original consistency." One day specimens 3 hours in air, the others 24 hours. Retempered specimens showed, in general, about half the normal strgth.

Similar results were obtained when the cem was moistened every 15 mins during the hour. In such cases, in practice, the strgth is sometimes increased by adding a little fresh cem.

Port cem mortars, retempered after standing an hour, failed to show marked deterioration, probably because Port cem sets more slowly than nat cem.

— 29 —

29. W. Purves Taylor, A S T M, Vol 3, p 376, '03.

29 a. Age; soundness. Ageing of finely ground cem permits hydration of the free lime, nearly always present, rendering it inert and preventing expansive action. Specimens, made with cem one wk old, were unsound; but, as the age of the cem increased, the soundness of the specimens improved until, when the cem was 5 wks old, the specimens were sound.

29 b. Fineness; soundness. The larger particles of coarsely ground cem are not readily hydrated. A cem, of which 33 % remained on a No 200 sieve and 13 % on No 100, checked and cracked in the boiling test; but became sound when reground until all passed the No 100 sieve and allowed to season for 2 weeks.

40. Prof Chas. L. Norton, E N, '02, Oct 23, '04, Jan 14.

Corrosion. Several hundred briquets of various mixes and consistencies with steel imbedded, subjected to air, steam and carbonic acid.

40 a. Steel clean when imbedded. 3 wks exposure.

Steel perfectly protected by neat cem in all cases, and where the mortar was mixt wet, so as to cover the steel with thin grout.

In conc, rust found only where voids or other defects existed.

40 b. Steel rusted when imbedded. 1 to 3 mos exposure. Changes, in size of steel, occurred only where conc had been poorly applied.

— **41** —

41. John S. Sewell, on **Baltimore fire,** E N, '04, Mar 24.

41 a. Results. "Concrete undergoes more or less **molecular change** in fire, subject to some **spalling.** Molecular change very slow. Calcined material does not spall off badly except at exposed square corners. **Efficiency,** on the whole, is high. Preferable to commercial hollow **tiles** for both floor arches or slabs, and col and girder coverings."

41 b. Reinfd conc cols, beams, girders, and floor slabs, at least as desirable as **steel work** protected with the best commercial hollow tiles.

41 c. "**Stone** conc spalls worse than any other kind, because the pieces of stone contain air and moisture cavities, and the contents of these rupture the stone, when hot. **Gravel** is stone that has had most of these cavities eliminated by splitting through them, during long ages of exposure to the weather. It is therefore better than stone for fire-resisting conc."

41 d. "**Broken bricks, broken slag, ashes and clinker** all make good fire-resisting conc."

41 e. "**Cinders** containing much partly burned coal, are unsafe, because these particles actually burn out and weaken the conc. Locomotive cinders kill the cem, besides being combustible. Cinder concrete is safe only when subjected to the most rigid and intelligent supervision; when made properly, of proper materials, however, it is doubtful whether even brickwork is much superior to it in fire-resisting qualities, and nothing is superior to it in lightness, other things being equal."

44. Edwin Thacher, A S C E, Trans, '05, Vol 54, pp 425, &c.

44 a. Effect of cold. Melan arch bridge, at Mishawaka, Ind, 3 spans, 110 ft each, built in temps ranging from 0° to 55° F. **Hot water** admitted to mixer. Conc laid at blood heat; warm enough to melt snow 48 hours later. Center arch completed with temp about 25° F. The next day, temp fell to 0° F. Two wks later, an ice jam carried out the centering and left the **arch unsupported.** No bad effects observed; settlement but little greater than with the other arches, centering under which was removed later and in the usual way.

44 b. Finish.

Bridge at Oconomowoc, Wis. Mortar face, 1 cem : 1 granite screenings : 1 torpedo sand. On the second day after completion, molds removed and surf rubbed with a soft stone and water.

Inman arch, Hohenzollern. 1 cem : 5 broken limestone. After setting 12 hrs, the loose cem was removed by water and brushes.

Pacific Borax Co's factory, Bayonne, N. J. Finished to represent coursed ashlar, by inserting wooden strips in the molds and dressing the faces with a pneumatic hammer. One man could dress from 300 to 600 sq ft in 10 hours by machine, 100 to 200 by hand. Good effect.

"Mr. Cummings produced a good finish by going over the surf with a wire brush while the cem was still green."

Utica & Mohawk Valley Ry viaduct, Herkimer, N. Y., and viaduct over rys at Jacksonville, Fla. "A very superior finish." For a hard wall, wet the surface and apply a thin 1 : 2 mortar with a brush. Rub surface with a piece of grindstone or carborundum, removing board marks, filling pores and producing a lather on the surf. Go over this lather, before it dries, with a brush dipped in water.

For a green wall (molds removed in less than 7 days,) use a thin grout of neat cem, instead of the 1 : 2 mortar. Remainder of process as above.

Use smooth molds, deposit wet conc directly against them. After removing molds, float the surf with a wooden float, using only sufficient mortar to fill the pores and give a smooth finish.

44 c. Corrosion.

Chicago. Iron rods, in limestone conc slabs which had covered sidewalk vaults for 8 or 10 yrs, rust-free. E. L. Ransome.

* See ¶ 4, p 1271. † Unreliable.

Steel perfectly protected by neat cem in all cases, and where the mortar was mixt wet, so as to cover the steel with thin grout.

In conc, rust found only where voids or other defects existed.

40 b. Steel rusted when imbedded. 1 to 3 mos exposure. Changes, in size of steel, occurred only where conc had been poorly applied.

— **41** —

41. John S. Sewell, on **Baltimore fire,** E N, '04, Mar 24.

41 a. Results. "Concrete undergoes more or less **molecular change** in fire, subject to some **spalling.** Molecular change very slow. Calcined material does not spall off badly except at exposed square corners. **Efficiency,** on the whole, is high. Preferable to commercial hollow **tiles** for both floor arches or slabs, and col and girder coverings."

41 b. Reinfd conc cols, beams, girders, and floor slabs, at least as desirable as **steel work** protected with the best commercial hollow tiles.

41 c. "**Stone** conc spalls worse than any other kind, because the pieces of stone contain air and moisture cavities, and the contents of these rupture the stone, when hot. **Gravel** is stone that has had most of these cavities eliminated by splitting through them, during long ages of exposure to the weather. It is therefore better than stone for fire-resisting conc."

41 d. "**Broken bricks, broken slag, ashes and clinker** all make good fire-resisting conc."

41 e. "**Cinders** containing much partly burned coal, are unsafe, because these particles actually burn out and weaken the conc. Locomotive cinders kill the cem, besides being combustible. Cinder concrete is safe only when subjected to the most rigid and intelligent supervision; when made properly, of proper materials, however, it is doubtful whether even brickwork is much superior to it in fire-resisting qualities, and nothing is superior to it in lightness, other things being equal."

— **43** —

43. Alex. B. Moncrieff, Engr in Chief, South Australian Govt Letter to authors, June 7, '04

43 a. Permeability.

Specimens. Conc blocks, 2 ft cubes (8 cu ft), for expts in connection with construction of **Barossa dam.** Ingredients same as used on dam. Agg ⅛" to 2", with varying voids. Preparation of aggs very carefully watched.

Treatment. Water brought to cen of block in ½" wrought iron pipe terminating in a T piece, wrapped with hemp which formed a bulb abt 4" diam.

Results. All the blocks became practically tight. Conc used in dam "was based upon the results of the expts principally with blocks

For abbreviations, symbols and references, see p 1251.

46 d. **Conc did not break or chip** under fire; but lost practically all strgth to a depth of 4″ from sides and bottom, and softened perceptibly thruout. The cem and most of the stone were thoroly calcined at surf, and, to a diminishing extent, to a depth of 4″. In all cases, a little **water appeared** in cracks running across the beams, especially with the richest mixtures and with temp at 212° F.

46 e. **Recommendations.** Materials should be well mixt, wet, by machine, and well tamped. Imbedment should be ≮ 2″; in important cases, 3″.

— 47 —

47. **John H. Quinton,** U. S. Geol Surv, "Expts on Steel-conc Pipes on a Working Scale," U. S. Water-Supply and Irrigation Paper 143, '05.

47 a. **Permeability.** To determine availability of such pipes under pres, for U. S. Reclamation Service.

Specimens. Seven reinforced hand-mixed conc pipes, 5 ft diam, 6″ thick, 20 ft long; each made in one section; one, same dimensions, in 4 secs. Skilled workmen. In 3 of the 7 pipes, and in 3 of the 4 secs of the 8th pipe, lime was used in the mixture.

The pipes varied greatly in texture. One of them "seemed to be of a crumbly nature, and it would have been easy to cut a hole through it." Another was "exceedingly hard."

Treatment. The pipes were tested with and without inside linings of cem and sand, etc, with and without lime paste. The Sylvester soap-and-alum wash (p 928), P and B waterproof paint, and other paints were tried: and clay was stirred up in the water within the pipes. Pressures up to 70 lbs/□″ = 161.5 ft. head.

Results.

47 b. In spite of all precautions, the pipes leaked, especially along tamping seams. **Leakage decreased greatly under pres,** as percolating water filled the pores with laitance; but in the mean time the leakage may be sufficient to damage foundations of pipe.

47 c. **Dry mixtures** gave the more permeable conc.

47 d. With carefully **graded gravels,** it was found difficult to secure uniform **distribution** of the diff sizes.

47 e. **Keep conc shaded** while mixing and placing.

47 f. Interruptions to work are least dangerous with **wet** mixtures. In tamping, avoid **displacement of reinforcement.**

47 g. Make **reinforcemt** strong enough to protect conc against tensile stress.

47 h. **Soap and alum** mixture of advantage in making conc; but ¾″ **plaster** found advisable on inside, in two coats, the first with lime paste, to retard setting; the second (applied when the first is dry) to be troweled smooth. When dry, apply thick neat cem wash.

47 i. Reinfd conc pipes not recommended for **heads** over 70 ft (30 lbs /□″). For short dists, special precautions may justify 100 ft (43 lbs/□″).

47 k. Conc pipes **liable to crack,** especially along tamping seams; but, even if cracked, probably drier and more durable than other kinds.

47 l. When the pipes were broken up, **rust appeared** upon only 1 rod, which was rusted all around for a length of about 1½″, where a large and long-continued leak had occurred. The pipe had been lined with a mortar containing sal ammoniac (ammonium chloride) and iron filings.

48. **Considère.** Beton und Eisen, '05, Vol 3

48 a. **Ductility.**

Specimens. Mixture, 400 kg Port cem, 0.4 cu m sand, 0.8 cu m limestone screenings. Beams 15 × 20 cm, 3 m long. Tension side reinfd with 2 iron bars 16 mm round, and 3, 12 mm rd. Bendg mom constant thruout measd length.

Treatment. One beam kept in water, one under damp sand, 6 mos

For Directory to Experiments, see pp 1303-7.

Results. Max unit stretches

kept under water	0.00107
" " damp sand	0.00050

No cracks discovered, altho the surf was smoothed with cem.

Strength unaffected.

— **49** —

49. R. Feret, "A Treatise on Concrete, Plain and Reinforced," by Taylor and Thompson, '05.

49 a. The injurious action of **sea water** is due chiefly to the **sulfuric acid** of the dissolved sulfates; hence, the cem should contain as little gypsum (lime sulfate) as possible. Port cem should be low in aluminum and in lime. The presence of puzzolanic material is advantageous. The conc should be dense and impervious.

— **50** —

50. Prof Ira H. Woolson, Report to Astoria Light, Heat and Power Co., '05.

50 a. Character; strength.

Strengths in lbs/□″

Port Cem, 1 : 2 : 4.	Tensile			Compressive		
	Max	Av	Min	Max	Av	Min
Sand & broken limestone	176	161	153	2000	1753	1441
Crushed* & broken limestone	282	194	138	3400	2449	2040

50 b. Sand contained < 1 % **loam;** all past ⅛″ sieve; 75 % past 20 mesh sieve. Hudson R bluestone (limestone) passing 1 ¼″ screen, retained on ⅜″ screen. Conc tampt wet in molds, 1 or 2 days in air, 5 or 6 in water. Air dried 4 to 7 wks. **Results,** see 50 a.

— **51** —

51. Prof R. C. Carpenter, Cornell Univ, Sibley Jour of Eng'g, Jan, '05.

51 a. Retardation of setting; gypsum (lime sulfate) $CaSO_4$, and **calcium chloride,** $CaCl_2$. Both ground dry with the clinker.

Initial set; paste bears a rod 1/12 inch diam, loaded with ¼ lb.
Final set; " " " " 1/24 " " " " 1 lb.

Time, in both cases, reckoned from time of mixing, and given in mins.

Results. Percentage by weight†

	0.0	0.5	1.0	1.5	2.0	2.5	3.0	3.5	4.0	5.0	6.0	7.0
	Time in minutes											
Initial $CaSO_4$	2	6	.	80	24	29	30	27	28	27	19	18
" $CaCl_2$	2	115	160	167	127	103	45	97	..	73	68	..
Final $CaSO_4$	52	87	.	157	114	79	69	72	45	59	37	59
" $CaCl_2$	52	274	272	234	212	180	182	185		160	145	..

51 b. E. Candlot (Ciments et Chaux Hydrauliques) found that **concentrated** solutions of $CaCl_2$ (such as 100 to 400 grams per liter) **accelerated** setting and hardening.

51 c. Addition of slaked lime to a cem containing gypsum which, with time, has lost its retarding effect.

	Initial, mins	Final, mins
2 % gypsum, no lime	12	15
" " + 5 % "	120	300

2 to 5 % of lime is useful in this respect, but not without the gypsum. The lime does not diminish the strgth.

— **52** —

52. Jas. C. Hain, Chic, Mil and St P Ry. E N, '04/Apr 28, p 413 E R, '05, Jan 28, p 103. **Sand; size and cleanliness.**

* ⅜″ crusher screenings; 87 % past ¼″ sieve, 40 % past ⅛″ sieve.
† 1 % = about 4 lbs $CaCl_2$ to a barrel of Port cem.

For abbreviations, symbols and references, see p 1251.

Specimens.

52 a. Impure sands.

1 3 Port cem mortars, made with

(a) sand of smooth rounded quartz grains, mixt with larger fragments of limestone shells. 92 % past No 24 sieve, 28 % past No 50;

(b) "St Paul standd sand," 54 % past No 24; 11 % past No 50;

(c) "Ottawa standd sand."

Results:

Relative tensile strgths (a) 100; (b) 137; (c) 107.5.

Sand (a) made excellent conc in a draw-span center pier.

1 : 3 Port cem mortars, with sand containing 3.2 to 15 % clay; strgths ≮ with clean sand With nat cem 1 : 3, and Port 1 : 2, the results were generally favorable to the cleaner sand.

Sand with 6 % clay gave stronger mortars before than after washing

Sands, to which 2 to 20 % rich loam had been artificially added, gave mortar testing somewhat irregularly but in general higher than those with clean sand.

52 b. Fine sand, with clay. A sand, all passing No. 100 sieve, 93.2 % passing No. 200 (therefore finer than most cem. See Specfs), and containing 12 % clay, gave a 1 : 3 Port cem mortar showing, at 6 mos and 1 yr, nearly the same tensile strgth as similar mortar made with "Ottawa standard sand," but the mortar was weaker at shorter periods.

— **53** —

53. Jas. C. Hain, Engr of Masonry Constn, Chic, Mil and St P Ry, E N, '05, Mar 16.

Oil. Tests by **Geo. J. Griesenauer.**

53 a. A neat Port cem briquet, 2 yrs old, exposed to occasional drippings of signal oil, began to disintegrate in 10 mos; but no recent conc structures were found perceptibly injured by oil. **A conc floor,** upon which lubricating and lighting oils had been stored for 6 yrs, was apparently unaffected Oil penetrated about 1/16". A piece of this floor, in oil 10 mos, still sound.

53 b. Port cem; neat; 1 : 3 sand; 1 : 3 limestone screengs; 18 briquets each; 4 days in air. Then saturated daily with signal oil; later less frequently. Cracks appeared in the 1 : 3 specimens in 2½ mos; in neat specimens in 5 mos. All the briquets disintegrated eventually.

53 c. Port cem; 54 briquets, neat; 36 briquets 1 : 3 sand. 7 d in air. Then saturated daily with oil; later, less frequently. Oils used; extract lard, whale, castor, boiled linseed, crude petroleum, signal. Cems made from limestone and clay, marl and clay, limest and slag. Lard oil disintegrated most of the briquets in from 2 wks to 2½ mos, but some remained sound for 9 mos. Signal oil (animal and mineral mixt) had nearly the same effect. Whale and castor oil affected only a few briquets; while petroleum and boiled linseed disintegrated no briquets. Petroleum diminished strgth somewhat. Boiled linseed formed a protective coating and did not affect strgth. As a rule, the neat briquets yielded first In general, briquets of limestone and slag yielded most; those of limestone and clay least.

53 d. Silica cem; neat, 1 : 1, 1 : 2, 1 : 3, sand. 1 briquet each. 2 yrs in water; 20 days in warm air. Signal oil 2 yrs. First 3 briquets sound; 1 briquet (1 : 3) disintegrating.

53 e. Linseed oil, Sylvester's process (p 1220), paraffine, and water glass (soda silicate) were applied, as **coatings,** to the briquets, but **all failed** to protect them against the action of the oils.

53 f. Rich conc, well made of good materials and well set and seasoned, is best for resisting oil. In practice, **conc structures** are rarely, if ever, saturated with oil, as were these specimens.

60. Wm. R. Baldwin-Wiseman, Instn C E Procs, '06, Vol 163, p 319.

60 a. Puddling effect of water flowing thru conc discs, 13″ diam, 6″ thick, 1 : 4 Port cem, crushed gravel passing 1″ ring. Sp gr of conc 2.23, 140 lbs/cu ft. In wooden molds 10 wks. Water, for pres, pumped from chalk formation, hardness reduced from 18° to 6°. Air temp 12° to 15° C = 54° to 59° F. Pressures, 24 to 60 lbs/□″ = 55 to 139 ft. Leakage as per Fig 4. Toward the close of the expts, small **stalactitic growths**

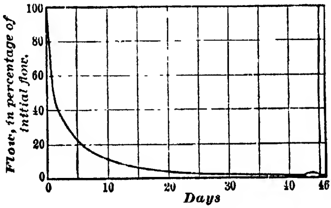

Fig 4. Puddling.

formed on bottom of test piece, and leakage was absorbed by evaporation. Near the surf, the water, under high pres, dissolved out some of the material, but deposited it in the pores farther on, where the pres had been reduced by passage thru the block.

— **61** —

61. Sanford E. Thompson. A S T M, Procs, Vol VI, 1906, p 379.

61 a. Consistency; effect upon density,* permeability and compressive strength.

Density and permeability specimens, 21 days old; comp strgth specimens 5¼ mos.

Specimens.

Atlas Portland cem; Newburyport sand, sp gr = 2.65; trap, sp gr = 2.78. 1 : 2.3 : 4.6 by vol; 1 : 2 : 4 by wt.

Consistencies used.	Water, % †
Dry. Like damp earth; water glistened on surf under hard ramming	5.4
Medium. Looked wet when mixed. Did not flow in mixing box. Slightly quaking	6.9
Wet	9.2
Very wet. Like thick soup. Settled to a level in mixing box. Required scoop shovels for handling. Slightly wetter than usual in building work	11.0
Extremely wet	13.7

* Density = vol of solid particles in unit vol of conc.
† Percentage of weight of cem, sand and stone.

For Directory to Experiments, see pp 1303-7.

Results. See Fig 5.

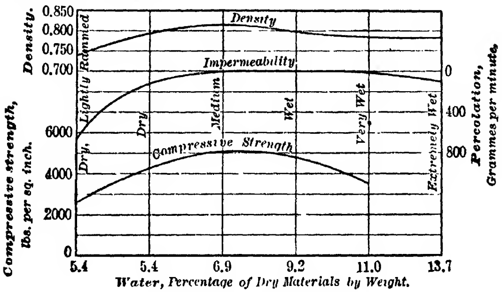

Fig 5. Consistency.

For a given consistency, the **percentage of water** depends upon the nature of the cem, and upon the size and dryness of the sand grains. A fine sand, or one with many fine grains, may require twice as much water as coarse sand requires.

61 b. Elastic modulus. Twelve 12″ cubes, deformations measd in 5″ gaged length. Averages of 4 specimens, 1 : 2 : 4; approx 1, 2, 6 and 17 mos old. Dry, 4,450,000 lbs/□″; medium, 4,200,000; very wet, 3,000,000 No appreciable increase of modulus with age.

61 c. Age; permeability. Blocks tested at 21 and 84 days, showed permeabilities abt as 2 : 1. Pressure, 80 lbs/sq in = 185 ft of water.

61 d. An excess of water washes out fine cem, forming **laitance,** reducing strgth and increasing permeability. **Thickness** of laitance formation, ⅛″ in very wet mixtures.

61 e. Mr. Thompson concludes that, in building and other reinfd work, the conc should be only wet enough "to flow sluggishly around and thoroly imbed the steel and permit smooth surfaces against the forms," and that medium or quaking conc is suitable for ordinary mass conc, such as foundations, heavy walls, large arches, piers and abuts.

— 62 —

62. A. Black, E N, '06, Aug 30, p 236.

62 a. Character of sand; strength and absorption.

Specimens.	Passing No 170 sieve.
A, crushed gneiss, screened thru ½″ mesh	90.8 %
B, Cowe Bay sand, much used in and about New York	95.8 %
C, fine clean silicious sand	95.5 %

Results. In 7 and 28 days, 1 : 2 and 1 : 3 mortars, A and B gave, in general, from 20 to 50 % greater tensile and comp **strengths** than C. In general, the **stronger** mortars showed the **higher absorptions.**

— 63 —

63. Alex. B. Moncrieff, E N, '06, Aug 30, p 227.

63 a. Briquets in water 2 yrs, in air 7 days and in oil 6 mos. In general, neat cem lost from 0 to 36 % strgth, while 3 : 1 gained from 0 to 65.5 %, by air drying and immersion in oil.

63 b. Briquets in air 7 days; then 6 mos in either oil or water. The neat cem briquets in oil were from 0 to 55 % weaker than the neat cem in water; the 3 : 1 briquets in oil were 49 to 79 % weaker than those in water.

For abbreviations, symbols and references, see p 1251.

63 c. Briquets in water 9 wks; others in water 4 wks, in air 1 wk and in oil 4 wks. With few exceptions, the neat cem briquets in oil were from abt 0 to 40 % stronger than like briquets in water, while the 3 : 1 briquets were from abt 0 to 63 % stronger than like briquets in water. Many of the oil-treated briquets "snapped like flint."

64. Prof Arthur N. Talbot, Univ of Ill. Bull, Vol IV No. 1, '06, Sept 1.

64 a. Adhesion and friction. '04.

Specimens and results.

Mix, 1 : 3 : 6.
Pull, in lbs/□" of net section;
Elastic limit, in lbs/□";
Adhesion, in lbs/□" of imbedded surf:

	Johnson bars		Round bars		Square bars		
	½"	¾"	⅜"	¾"	⅜"	½"	¾"
Pull............	71,412	34,500	31,500	21,500	35,656	26,510	20,860
Elas lim	60,000	58,300	42,500	40,500	45,000	33,300	35,000
Adhesion	595	420	249	315	297	286	325

With all the **Johnson bars**, the specimens split or broke. All the **plain rods** slipped. 6 of the 11 Johnson bars, and 4 of the 11 bars ⅜" square, were "struck 6 quarter-swing **blows** with a 10-lb sledge," reducing their adhesion by abt 5 to 20 %.

Specimens.

64 b. '05–6. Cylinders, 6" diam, 6" and 12" long; 60 days old Mixture of Am Port cems, tensile strgth, neat, 723 lb/□" at 7 days; 1 : 3, 354 at 7 ds, 533 at 75 ds, coarse mortar sand; broken limestone, screened thru 1" and over ¼" screen. Metal, elas lim, lbs/□"; Mild steel (M), Round 38,000; Flat, 45,000; Cold rolled shafting (C), 87,000; Tool steel (T) 53,000.

Results.

No. of tests	Steel	Size	Mix	Imbedded length, ins.	Lbs/□" imbedded surface: Adhesion a	Friction f	f/a
6	M	½" round	1 : 3 : 5.5	6	372	210	0.57
6	"	"	1 : 2 : 4	"	412	227	0.55
6	"	⅝" round	1 : 3 : 5.5	"	355	227	0.64
4	"	"	1 : 2 : 4	"	465	297	0.64
3	"	½" round	1 : 3 : 5.5	12	373	268	0.72
4	"	"	1 : 2 : 4	"	404	266	0.65
3	"	⅝" round	1 : 3 : 5.5	"	402	228	0.57
3	"	"	1 : 2 : 4	"	414	223	0.54
3	"	1½ × 5/16"	1 : 3 : 5.5	6	125	84	0.67
3	C	1" round	"	"	136	67	0.49
3	"	½" round	"	"	157	50	0.32
3	T	¾" round	1 : 3 : 6	"	147	...	...

Rich mixture generally superior. **Cold rolled** shaftg and **tool steel** generally inferior, owing to uniformity of sec and smoothness of surf.

Results. See Fig 5.

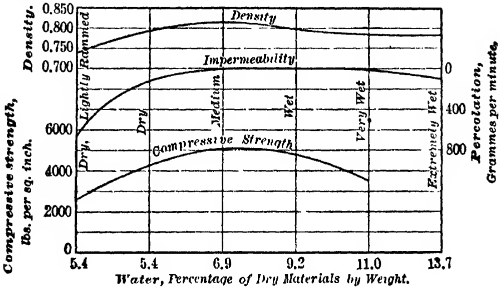

Fig 5. Consistency.

For a given consistency, the **percentage of water** depends upon the nature of the cem, and upon the size and dryness of the sand grains. A fine sand, or one with many fine grains, may require twice as much water as coarse sand requires.

61 b. Elastic modulus. Twelve 12″ cubes, deformations measd in 5″ gaged length. Averages of 4 specimens, 1 : 2 : 4; approx 1, 2, 6 and 17 mos old. Dry, 4,450,000 lbs/□″; medium, 4,200,000; very wet, 3,000,000 No appreciable increase of modulus with age.

61 c. Age; permeability. Blocks tested at 21 and 84 days, showed permeabilities abt as 2 : 1. Pressure, 80 lbs/sq in = 185 ft of water.

61 d. An excess of water washes out fine cem, forming **laitance,** reducing strgth and increasing permeability. **Thickness** of laitance formation, ⅛″ in very wet mixtures.

61 e. Mr. Thompson concludes that, in building and other reinfd work, the conc should be only wet enough "to flow sluggishly around and thoroly imbed the steel and permit smooth surfaces against the forms," and that medium or quaking conc is suitable for ordinary mass conc, such as foundations, heavy walls, large arches, piers and abuts.

62. A. Black, E N, '06, Aug 30, p 236.

62 a. Character of sand; strength and absorption.

Specimens.	Passing No 170 sieve.
A, crushed gneiss, screened thru ½″ mesh	90.8 %
B, Cowe Bay sand, much used in and about New York	95.8 %
C, fine clean silicious sand	95.5 %

Results. In 7 and 28 days, 1 : 2 and 1 : 3 mortars, A and B gave, in general, from 20 to 50 % greater tensile and comp **strengths** than C. In general, the **stronger** mortars showed the **higher absorptions.**

— 63 —

63. Alex. B. Moncrieff, E N, '06, Aug 30, p 227.

63 a. Briquets in water 2 yrs, in air 7 days and in *oil* 6 mos. *In general,* neat cem lost from 0 to 36 % strgth, while 3 : 1 gained from 0 to 65.5 %, by air drying and immersion in oil.

63 b. Briquets in air 7 days; then 6 mos in either oil or water. The neat cem briquets in oil were from 0 to 55 % weaker than the neat cem in water; the 3 : 1 briquets in oil were 49 to 79 % weaker than those in water.

For abbreviations, symbols and references, see p 1251.

68 b. Tensile strength.

Oil in mix	Tensile strength, lbs/□″		
	1 day	7 days	28 days
None	430	696	743
2 % linseed	180	493	572
2 % engine	332	689	696

72. Wm. B. Fuller, Natl Assn of Cem Users, Procs, '07, pp 95–7.

Grading and proportions.

72 a. Tests of 6 beams, 6″ square, 6 ft long; 1 cem to 8 of sand and stone; **rupture moduli** in lbs/□″: 1 : 2 . 6, 319; 1 : 3 : 5, 285; 1 : 4 : 4, 209; 1 5 : 3, 151; 1 : 6 : 2, 102; 1 : 8 : 0, 41.

72 b. With a given percentage of cem, the **densest** mixture of sand and agg gives the strongest, the least permeable and therefore the most durable conc, and that which works most easily and therefore best fills up voids and corners.

— 73 —

73. Commission du ciment armé, Paris, '07.

73 a. Shrinkage and expansion. Conc shrinks while hardening in air, and expands under water.

* Material, larger than 0.2″ diam (abt 62 to 68 % of total) graded in accordance with the recommendations of the authors. See Plain Concrete, ¶¶ 23 to 25, p 1257.

For Directory to Experiments, see pp 1303-7.

70 e. After cooling from 750° F, both trap and limestone prisms were covered with minute cracks. Under higher temps, these cracks increased in number and in size, and the prisms warped and disintegrated after cooling from 1500° F.

70 f. The **trap and cinder** conc specimens remained **sound**, while the **gravel** conc specimens **cracked** and crumbled in pieces, probably owing to high **expansion** coeff of quartz, and to the fact that this coeff in one direction, is double that in the perp direction.

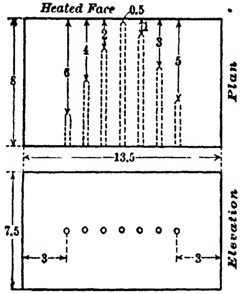

Fig 7. Thermal Conductivity. Dimensions in inches.

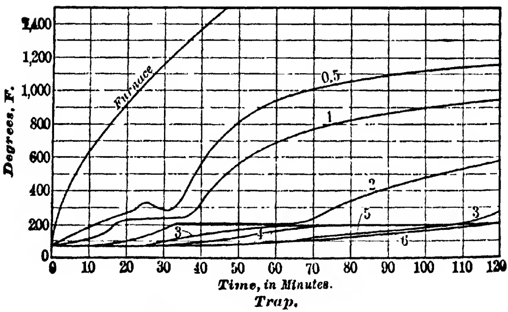

Fig 8. Thermal Conductivity.

70 g. Thermal conductivity, '07, p 404. Figs 7 and 8.

Specimens. Conc blocks, with holes as in Fig 7. Dimensions in inches. Thermo couple in each hole. Mixture as in **70 a.**

Treatment. Specimens in molds 24 hrs, in water 48 hrs, kept moist 2 or 3 wks, allowed to dry well. Age, at test, about 2 mos. Blocks placed in furnace doorway.

Results. Fig 8 shows, for one of the trap conc specimens, the **times**, in mins, reqd **to transmit the furnace temps** thru diff thicknesses of conc. Each curve is marked with this thickness in ins. Drop of curves, at and near 200° F, attributed to **steam generation.**

Louis, 80 to 95 lbs/cu ft, passing 1⅛" screen; abt half the stones larger than 1", about one-tenth of the stones less than ½"; voids 42 to 48 %. Voids, in 3 sand + 5 agg, 16 to 19 %.

Treatment. Comp specimens left in molds in air 1 day, beams 2 ds; then all in water 2 wks; then in air, protected from drafts, until tested. Comp specimens, 1 mo and 1 yr old, loaded 4 to 8 times per min; beams, 1 mo, 6 mos and 1 yr, loaded 2 to 4 times per min.

Results. Effect of rate of repetition insignificant; but believed to increase rapidly with rates above 10 per min.

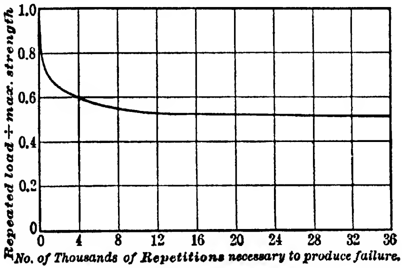

Fig 9. Fatigue.

Fatigue. The curve, Fig 9, fairly represents the results obtained under these varying conditions.

76 c. Conc, repeatedly stressed, below the fatigue limit (i. e., below about half max strgth, see Fig) "has imparted to it a **definite elastic limit,** within which stresses are proportional to strains" (i. e., within which the **elastic modulus,** E, is constant).

76 d. Fatigue and Adhesion.

Specimens. Plain ⅝" square steel bars imbedded in conc as above. Specimens made with great care and very thoroly tamped.

Treatment. In molds 2 days, in water 7 ds, in air 3 wks. 30 fatigue specimens subjected to "a combined blow, pressure and the accompanying vibration"; 150 blows per min, each blow = 740 inch-lbs. Av, 50,000 blows to each specimen.

Results. Av initial **adhesion,** 125 lbs/□" of imbedded surf; **friction** (after slip) 90 lbs/□". **Unfatigued specimens,** 150 and 100 lbs/□" respectively.

76 e. Fatigue under continued load. p 318. 2 conc prisms remained unaffected for a month under 90 % of their crushing strgth. "A few conc blocks failed in comp in a few hours under constant pres of higher %." A reinfd conc beam failed in 10 mos under 90 % of its breakg load.

Pres from 71 to 284 lbs/□"; Avge	0.554	0.044	0.159	0.294
After remaining under 284 lb/□" 2 hrs	0.349	0.034	0.133	0.278

78 c. Percolation "very nearly **proportional to pressure.**"

78 d. 3 blocks, 1 year old. Block	A	B	C
	Flow, in grams/min per lb/□"		
At 284 lb/sq in	0.067	0.111	0.108
Raised to 412 lb/□"	0.077	0.114	0.126
Reduced to 284 lb/□"	0.068	0.114	0.111

"as if the effect of the momentary increase of pres had been to open new passages for the water, or partly to clear out the passages already existing."

— 79 —

79. Wm. B. Fuller and S. E. Thompson, A S C E, Trans, '07, Dec, Vol. 59, p 67.

Strength, density and permeability, as affected by **proportions and character of sand and agg.** Expts at Jerome Park Reservoir, New York.

79 a. Specimens. Port cem, as received for use on the reservoir; agg (1) stone and screenings from crushers at reservoir, mica schist, 35 % mica, which, in mortar or conc, "does not form planes which affect the strgth seriously." (2) Cowe Bay gravel and sand, dredged from river ("water-worn rounded bank gravel and sand, thoroly clean, and consisting almost entirely of quartz particles." Sp gr abt 2.65). Max size of stone, 2¼", 1", ½".

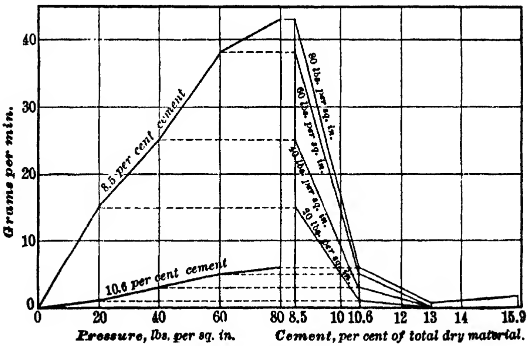

Fig 10. Permeability.

Tests were made with "**graded mix**" (proportions giving max density of agg) and "**natural mix**" (1 : 2.5 : 6.5, 1 : 3 : 6, 1 : 3.5 : 5.5).

Results.

79 b. Size of aggregate; strength and density.

Max stone size, inches	2¼	1	½
Relative strength.			
Compression	1.00	0.83	0.72
Transverse	1.00	0.91	0.75
Cem reqd for equal strgth, relative	1.00	1.17	1.32
Relative **density**	1.00	0.96	0.93

For abbreviations, symbols and references, see p 1251.

79 c. Kind of aggregate. Sand vs screenings. Relative strengths and densities.

	Comp strgth	Transv strgth	Density
Sand and stone	100	100	100
" " gravel	94	89	102
Screenings and stone	67	85	98

79 d. Graded mix gave **density** = 1.14 × density with natural mix; for equal strgth, graded mix reqd 0.88 × the **cem reqd** with nat mix.

(This means an **av saving** of about 25 cts **per cu yd** of conc. Allen Hazen, Trans, A S C E, Vol 59, p. 150, Dec, '07.)

79 e. An excess of fine or of medium **sand,** or a deficiency of fine sand in a lean conc, diminishes strgth and density.

79 f. Strength and density max when mortar just fills voids.

79 g. Permeability. See Fig 10. "Little is known of the action of conc in resisting the flow of water." As betwn "diff proportions and diff sizes of the same class of materials, the laws of watertightness are somewhat similar to those of strgth." With given percentage of cem, the **densest** specimens are usually **most watertight.** With equal densities, the **richest** specimens are **most watertight** (See Fig). The ratios, however, are very diff from those of either density or strgth, a slight diff in the composition producing a great effect upon the watertightness. "**Diff kinds of agg** produce very diff results in watertightness." Fig shows effect of **pressure** upon **permeability.**

79 h. Conc with Jerome Park stone and screenings gave very much higher rates of percolation thruout (max, 369 grams per min) than that with Cowe Bay sand and gravel. Conc with stone and sand gave about half the rates shown in Fig 10.

79 i. Permeability is sometimes greater with **large** and sometimes with **small stones.** Results especially erratic with the Jerome Park reservoir broken stone and screenings.

79 j. "**Permeability** decreases materially with **age;**" increases much more rapidly than the **thickness of the conc** decreases,

less with sand and gravel than with stone and screenings;
" " " " " " " " " sand;
" " " " stone " " " " screenings;

— 80 —

80. Richd H. Gaines, New York Board of Water Supply, A S C E, Trans, Vol 59, '07, Dec, p. 159.

80 a. Permeability and strength; Clay and alum.

Specimens. Mortar, 1 : 3, Portland, Cowe Bay sand. Tensile tests on standard briquets; comp and tensile tests on 2″ cubes. Age of specimens, 28 to 30 days. Pressures, 40 and 80 lbs/□″.

Results. (1) Replacing the mixing water with a 2.5 to 5 % (1 to 2 % sufficient) **alum** solution gave nearly complete **impermeability.**

(2) Replacing 5 to 10 % of the sand with dried and finely ground **clay,** and (3) combining (1) and (2), gave still better results.

The clay specimens (with and without alum) showed from 12 to 18 % gain in **strength** over those without clay.

The process is based upon a **theory of physico-chemical action** between ions of the electrolyte (alum) and the colloid (glue-like) molecules of the clay.

None of the **processes hitherto in use,** and examined, were found suitable for extensive use.

Slaked lime slightly decreases **permeability,** but this advantage is more than offset by loss of **strength.** There is no chemical reason why this should be otherwise.

For Directory to Experiments, see pp 1303–7.

Elastic relations, pp 27–32. **Specimens:** Square prisms; measured length, 35 cm (13¾"). 1 part Mannheim Port cem, with 3 parts of a mixture of Rhine sand and gravel consisting of 3 parts sand, 0–5 mm; 2 parts gravel, 5–20 mm. (0.197"–0.78"). Water, 14 %. Each stress maintained 3 mins. Some of the specimens tested in tension; the others in comp.

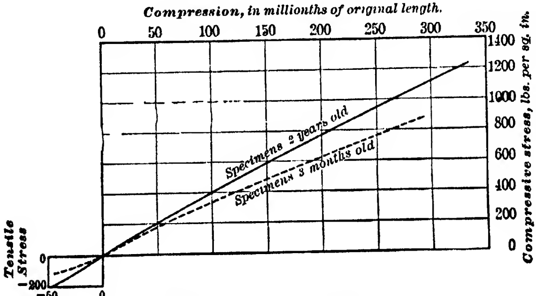

Fig 11. Stress and Stretch.

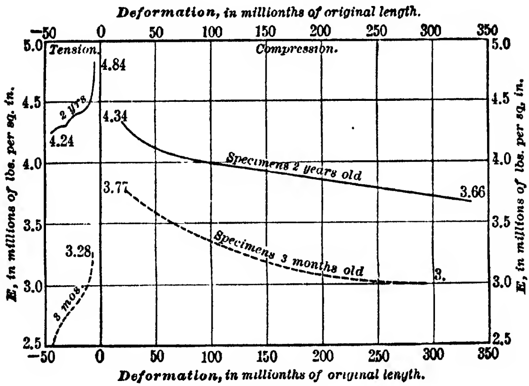

Fig 12. Elastic Modulus.

Results. **Unit stresses and stretches** as in Fig 11. Ult tensions, lbs/□" : 3 mos, 149; 2 yrs, 224.

Elastic Modulus, E, See Fig 12.

With mix 1 : 4, for a given stress in comp. **E** was in general from 15

For abbreviations, symbols and references, see p 1251.

to 20 % less than with 1 : 3. In tension, **E** was more nearly the same for both mixes.

With water 8 %, for a given stress, **E** was in general from 10 to 20 % higher than with water 14 %.

81 b. Shear. Fig 13. Dimensions in centimeters. Prisms, 18 cm square, 40 cm long, p 40. Mixture of sand and gravel as in Expt 81 *a*.

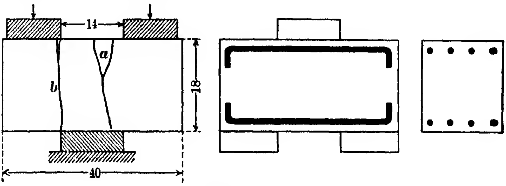

Fig 13. Shear.

Plain. Specimen first cracked, as beam, at *a*. Pres then increased until shearing crack, *b*, appeared.

Mix	Water %	Age	No. of Specimens	Ult av shear, lbs/□″* Observed	Calculated†
1 : 3	14	2 yr	3	936	980
1 : 4	14	1.5 m	3	530	550

Reinforced. The bars (1 cm diam) served merely to hold the specimens together, so that the pres could be increased as desired. The conc sheared first.

Mix	Water %	Age	No of specimens	Ult Av shear, lbs/□″ Concrete	Steel
1 : 4	14	1.5 m	2	522	46400
1 : 4	14	1.5 m	3	484	50800

81 c. Torsion, p 45. Mix, 1 : 4. **4 solid cylinders,** 79 to 98 days old; 26 cm diam; length under exp, 34 cm. Hexagonal heads. M = torsional moment; R = radius of cyl;

t = torsional stress in extreme fibers (see p 500, this book) = $2\ M/\pi R^3$
t, in lbs/□″; max, 275; mean, 243; min, 189.

3 hollow cyls, as above, 52 to 55 days old; inner diam abt 15 cm; r = inner radius.

$t = 2\ M\ R/\pi\ (R^4 - r^4)$,
t, in lbs/□″; max, 134; mean, 126; min, 112.

The much higher unit strength of the solid cylinders as given by the formulas, is attributed partly to their somewhat greater age, but chiefly to the increase in unit stress from the circumf inward, owing to which the material near the center transmits more than its share of the torsional stress, and thus relieves the outer portions.

* = ½ total force applied ÷ area of one shearing surf.

† From ult tensile strgth, t, and ult comp strgth, c, of test pieces of same mix and age, and formula, shear = $\sqrt{tc}$.

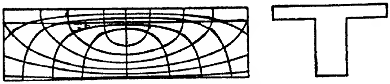

Fig 20. Diagonal Stresses.

— 82 —

82. Sanford E. Thompson. A S T M, Procs, '08, Vol 8, p 500.

82 a. Permeability. Effect of admixture of **slacked lime.**

Specimens. Cylindrical blocks, 20″ diam, 16″ thick; Lehigh cem, good av bank sand, conglomerate rock resembling trap in character; "a soft, mushy mix, such as would be adopted in construction." Pine Cone lime from Rockland, Me. Lime stated in % of wt of dry cem. Mixtures as follows.

1 : 2 : 4 conc with 0 %, 4 %, 7 % and 10 % lime; 8 % preferred;
1 : 2.5 : 4.5 " " 0 %, 6 %, 10 % " 14 % " ; 12 % " ;
1 : 3 : 5 " " 0 %, 8 %, 14 % " 20 % " ; 16 % " .

Treatment. Water, under pres, introduced into cen of block.

Results, 1 : 2 : 4 and 1 : 3 : 5, see Fig 21. 1 : 2.5 : 4 gave results intermediate betw the other two.

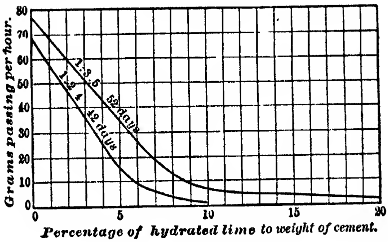

Fig 21. Permeability; Lime.

82 b. Coarser sand requires more lime, and vice versa.

82 c. If pressure is to be applied within a month, it will be better to use say 10 %, 15 % and 20 % respectively, instead of 8 %, 12 % and 16 % as recommended under Expt 82 a.

82 d. Lime paste occupies about $2\frac{1}{4}$ times the **bulk of paste** made with equal wt of Port cem, "and is therefore very efficient in void filling." The **cost of large waterproof work may be reduced** by using, with lime, a leaner conc than would otherwise be suitable.

— 83 —

83. Richard L. Humphrey, plain conc beams, cubes and cylinders, comp and transv strgths and the elas relations. "The Strgth of Conc Beams," U S G S Bull No. 344, '08. Tests to determine the effect, upon **transverse and compressive strength,** of (1) **age** of specimen, (2) **consistency** of mix, (3) character of **aggregate.**

83 a. Specimens. Unreinfd conc beams, cubes and cyls. Cem, a mix of 9 Port cems. Meramec R sand, "composed of flint grains having comparatively smooth surfs." "The granulometric analysis, p 1346, shows the sand to be rather finer than desirable."

Properties of sand and aggregates used.

	Sp gr	lbs/ cu ft	voids %	Meshes per inch of screen: 200	100	50	30	10	Size of mesh, ins: ¼	½	¾	1¼
				Percentage passing sieve or screen								
Cinders	1.53	47	51	2.84	4.17	6.5	10.5	21.1	37	60	81	100
Granite	2.59	95	41	1.59	2.29	3.2	4.4	8.5	20	58	99	100
Gravel	2.45	102	33	0	0	0	0	1.0	43	79	95	100
Limestone	2.49	98	37	2.96	3.48	4 2	5.2	10.7	29	61	96	100
Sand	2.60	101	38	0.20	1.30	13.9	64.0	97.0	100	..	..	...

Proportions. 1 : 2 : 4, by vol, except the cinder conc, which was nearer 1 : 2 : 5. All conc mixed in a mortar-driven cu-yd mixer, equipped with charging hopper. Mixed 2 mins dry, 3 mins wet, then dumped on cem floor, shoveled into barrows and wheeled to molding floor. Each batch sufficient for 2 beams, 8″ × 11″, 12 ft span, two 6″ cubes and 2 cyls, 8″ dia, 16″ long.

"**Wet:**" smooth and somewhat viscous immedy before dumping. Flows back from ascending side of mixer without tendency to break at top. When dumped, shows neither voids nor individual stones. Splashes when tamped. When finished, water stands ¼″ to ½″ deep over surf of mold.

"**Medium**": smooth, but tending to lump. Flows less smoothly than "wet," part flowing back smoothly and part breaking over in lumps. When dumped, looks somewhat lumpy, showing stones, but no voids. Stones evenly coated with mortar. No water collects on surf in mold. Surf easily finished with trowel.

"**Damp**"; granular. But little tendency to lump. Carried to top of mixer on ascending side; falls in individual stones and fragments of mortar. When dumped, shows stones and voids. Resists tamping. Compacts under hand tamping. Cannot be finished smooth with trowel.

Conc placed in oiled steel molds, in 3 nearly equal layers, and hand-tamped. "Great care was taken to tamp all the concs in the same manner."

Treatment. All molds were removed at end of 24 hrs, and pieces transferred to moist room. Sprinkled 3 times daily.

The beams were so supported, just prior to test, that the sums of moments and stresses, then existing in the measd length, were equalized, so that all fibers, in that length, then had same length as when unstressed, and the deformations, within the measd length, were thus measd from zero.

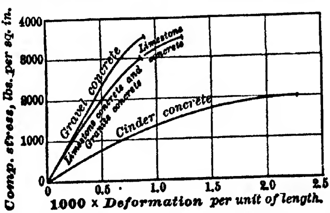

Fig 22. Stress-stretch curves for different aggregates.

Results.

Stretches and comp stresses as in Fig. 22. Medium consistency. Age, 26 weeks.

For abbreviations, symbols and references, see p 1251.

Strength of Concrete.

Results, in general, averages of 3 specimens.

— 84 —

84. R. G. Clark, Inst C E, Procs, Vol 171, '08, p 115.

84a. Time of setting increased by **aeration** and by **addition of agg.** A cem, which, neat, sets in an hr, will make a conc requiring 4 or 5 hrs to set.

— 85 —

85. Hanisch and Spitzer, Morsch, Der Eisenbetonbau, '08, pp 32–33.

85a. Rupture modulus, 6 $M / b d^2$, **and direct compressive and tensile strength.**

Specimens.

Conc, 1 : 3.5. Six plates, 268 days old, 60 cm (24″) wide, 7.8 to 11 cm (3 to 4.5″) thick; span, 150 cm (60″).

Treatment. Plate broken transversely; comp and tension test pieces made from the fragments.

Results. Stresses in lbs / □″.

	Rupture modulus	compression	tension
max	775	5000	412
mean	682	4380	356
min	614	3640	284

Comparison of the values for tension with the rupture modulus shows that the **formula,** rupture mod = 6 $M / b d^2$, is not applicable to materials in which, as in conc, the elas mod varies widely, and that the rupture moduli, obtained by means of the formula, are to be used only as a means of comparison.

— 86 —

86. Richard L. Humphrey and Wm. Jordan, Jr., U S G S, Bull No. 331, '08. Results of Tests made at the Structural-Materials Testing Laboratories, St. Louis, '05-7.

86 a. Gravel screenings. In general the tensile and comp strgths of mortars seem to increase with density of screenings.

* m = (depth of neut ax below top of beam) ÷ (total depth of beam).

† "Rupture modulus" = 6 $M / b d^2$, lbs / □″; M = moment under max load.

‡ Cylinder did not break.

For Directory to Experiments, see pp 1303–7.

86 b. Stone screenings. In general, strgth of mortar was greatest with screenings most nearly uniform in grading. The **strength of the stone** itself, from which the screenings are derived, has an important bearing on the strgth of the resulting mortar.

86 c. Density of mortars is greatest with densest **sand.**

86 d. Sand mortars. Tensile, compressive and transverse **strengths** were invariably much **greater with dense sands** than with those having a larger percentage of voids.

86 e. Greatest strgth obtained when sand is uniformly graded.

86 f. A "typical mix" of 7 Port cems, like the separate brands, reached max tensile **strength** in 90 days. Like the best of these, it maintained this max to 180 ds, and its subsequent loss, at one yr and later, was no greater than for the best of the separate brands.

86 g. Age of briquet. Tests after 180 days showed greater uniformity than at 90 days and shorter periods.

86 h. After the 180 and 360 day tests, the strgths of all the sand mortars were reasonably close to one another, showing that considerable variation in **early strength** does not seriously affect the **later strength.**

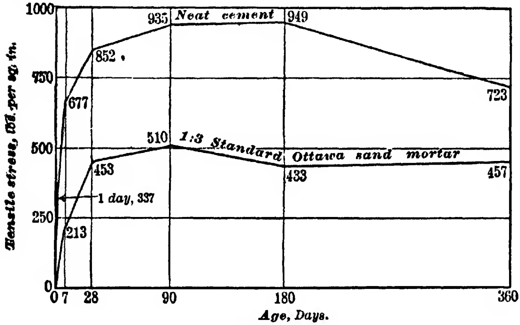

Fig 23.

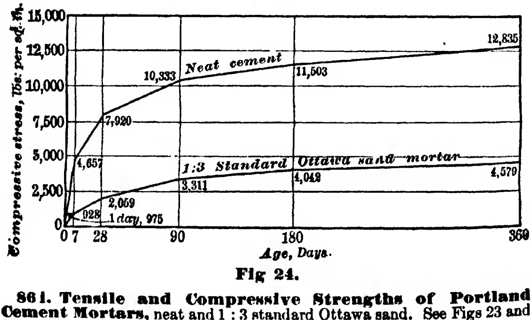

Fig 24.

86 i. Tensile and Compressive Strengths of Portland Cement Mortars, neat and 1 : 3 standard Ottawa sand. See Figs 23 and 24. Each curve represents an av of 10 tests.

For abbreviations, symbols and references, see p 1251.

Specimens. The cem was a mixture of equal parts of 7 diff brands. See Expts 86 f, 86 g and 86 h.

Test pieces, in molds, stored in moist closet 24 hrs; then kept in running water, abt 70° F, until tested. Tension briquets 1 sq inch section. Compression specimens, 2″ cubes.

Results as in Figs 23 and 24.

— 87 —

87. W. N. Willis, South & Western R. R. E R, '08, Jan 18; E N, '08, Feb 6, p 145.

87 a. Mica; water required; strength.

Specimens.

Sieve No	10	20	50	100
% of mica passing	100	29	10	4.5

Sand, Ottawa standd. Mortar 1 : 3 sand, or 1 : 3 sand and mica by wt.

Results.

Mica; % of weight of sand	0	5	10	15	20
Voids, % in Ottawa sand	37	...	...	...	67
Relative **sp gr** of Ottawa sand	100	...	...	...	80
Mixing Water required; relative	100	..	...	...	300
Tensile strength, 6 mos, relative	100	64	62	59	40

The smoothness of surf of the mica particles renders their adhesion low.

— 88 —

88. Prof J. L. Van Ornum, Washington Univ, St. Louis; for Reinforced Concrete Constr Co., St. Louis. E N, '08, Feb 6, p. 142.

88 a. Adhesion.

Specimens. Plain round steel rods, diams, ½ to 1¼″, imbedded in 12″ × 12″ prismatic blocks of 1 : 2 : 4 conc, 90 days old. Medium steel rods imbedded 25 diams; high carbon steel rods, 40 diams.

Results. See table below, in which.

for Steel:

s = Ult strgth, in thousands of lbs/□″;
s_e = Elastic limit, in thousands of lbs/□″;
e = Elongation, %;
E = Elastic mod, in millions of lbs/□″.

for Steel and concrete:

a = Area of imbedded surf, □″;
B = Adhesion, lbs/□″ of a;
F = Friction after slipping, lbs/□″.

Steel	Steel				Steel and Conc.			
	s	s_e	e	E	a	B	F	F/B
Medium								
Max	60 9	40.5	29.0	29.9	126.8	460	380	0.826
Av	58.6	39.1	26.1	29.5	62.1	408	342	0.838
Min	55.6	38.4	22.5	28.6	21.7	370	310	0.838
High Carbon								
Max	109.6	60.7	20.7	30.6	198.3	470	280	0.596
Av	92.6	56.1	17.6	29.8	92.1	392	240	0.613
Min	83.9	53.1	15.7	28.9	32.7	330	200	0.606

In all cases, the total pull which overcame the adhesion exceeded that which brought the steel to its elas lim.

— **90** —

90. Eng News, '08, Aug 27, p. 238.

90 a. Sea water. Charlestown, Mass, Navy Yard.

Nonreinforced arches, built '01, by Bureau of Yards and Docks **Tidal salt water**, not highly polluted, but often **freezing;** range of tide 10 ft. Specification called for "continuous construction from pier to pier of the arch rings." 3″ mortar face, 1 : 1. Mass conc 1 : 2 : 4 for 2 ft back from face, 1 : 3 : 6 interior; "a standd cem and a local gravel." Probably porous. No special effort toward density or waterproofing. Specfn provided: "The contractor must furnish satisfactory evidence of the durability in sea water of the brand of cem he proposes to furnish." The showing spandrel walls were built after completion of arch ring. Dry, well-tamped. Serious disintegration. Damage mainly betw H W and L W. Conc backing considerably affected.

— **91** —

91. U. James Nicholas, Melbourne, Victoria. E N, '08, Dec 24, p 710.

91 a. Electrolysis in cement mortars.

Specimens. 16 cylinders, 8″ diam, 8″ high. Standd Port cem; coarse sand, voids 51 %. Mortar tamped in 1½″ layers until a little water flushed to surf. Positive electrode, normally a 1″ steel pipe, 12″ long, lower end corked, immersed, in axis of cyl, to depth of 5″ in conc.

Treatment. Cyls set in fresh water ≮ 28 days. 8 cyls tested with **constant current** of about 0.1 ampere; 5 with **constant potential** of about 115 volts (higher currents, one with reversed current); 3 not subjected to current. For current, cyls placed in 3 % salt solution in separate metal pails (which normally formed the negative electrodes), and connected in series. Cyls from 29 to 57 days old at beginning of test.

Results.

All cylinders, under current, **cracked.** Cracks attributed to accumulation and pres of liberated gases. Cracks at first hair-like, exuding moisture, which dampened adjacent surf. Cracks widened under continued current. With constant current, cracks appeared when resistance reached max. Resistance in general inversely proportional to **percentage of sand.** Cyls Nos 1 and 2 easily pried open. In Nos 2 and 9, **steel pipe** was **rusted** and pitted on outside, adjacent to crack. With (const potential) reversed current (No 12), no rust or pitting.

Cyls not subjected to current were not cracked. They reqd about 20 blows, with heavy hammer and cold chisel, to break them. No rust.

	Constant Current, 0.1 ampère No of Specimen.								Constant Potential, 115 volts No of Specimen.

* To first crack. † Approximate maximum resistance.

For abbreviations, symbols and references, see p 1251.

— 92 —

92. "H," of Lafayette, Ind. *Letter in E N, '08, Dec 31, p. 751.*

92 a. **Clay.** In conc for cols, gravel contained 5 % clay, which floated to top in churning, and left 1 ½" of worthless material near top of col.

— 93 —

93. **A. Q. Campbell,** Ogden, Utah. E N, '08, Dec 31, p 751.

93 a. **Grading and impermeability. Finish.** 2 million gal rectangular reinfd conc water tank, 20 ft deep. Floor, 6" thick; walls 8 to 18". 1 cem, 2 ordinary sand, 4 stone (quartzite boulders, porphyry and flinty limestone) crushed to 1", with dust; "a heavy percentage of crushed dust and sand"; machine mixt; "consistency that would almost pour." Floor laid in blocks about 15 ft sq, "allowing a half-lap of 2 ft;" walls in continuous 20" layers. Finish of 1 : 1 cem and crusher dust, applied with ordinary broom trimmed short. Clear water. No perceptible checking in surf. Apparently no seepage.

— 94 —

94. **John C. Trautwine, Jr.** '09.

94 a. **Density of sand: shape of grain.** 100 measures of rounded sand grains, or of angular crushed quartz grains, poured very slowly into 60 measures of water. Exps Nos 1 and 2 were made with sand grains; Nos 3 and 4 with crushed quartz grains. The left side of each diagram, Fig 25, represents the bottom of the vessel; and the numerals, 94, 121, etc., show the elevations of the surfs of sand and of water respectively, after the sand grains had been poured into the water.

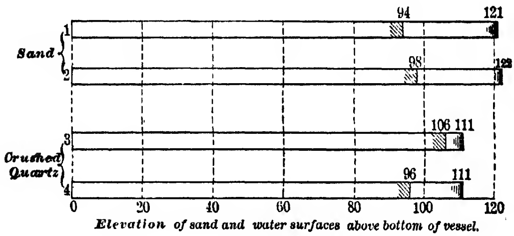

Fig 25.

In No 4, the crushed quartz, in the water, was stirred, from time to time, during the pouring, in order to liberate any air which, in spite of the slowness of pouring, might have been carried into the water with the sand grains. The fact that the water stands at practically the same ht in 4 as in 3, indicates that no more air was carried down in 3 than in 4, and that the stirring merely brought the grains into closer contact than when left to themselves.

Outline of Contents.

For lists of Specifications for Concrete, see pp 1352, 1353.

In order to compare intelligently the requirements of diff specfns, the character of the work involved must of course be taken into account.

DIGEST.

Cement.

1. Brand. Portland or natural, **NY**; Port just under lower miter sill, nat elsewhere in foundations, Port in lock walls except for a backing, 2 ft deep, at base, Port and nat bonded together, **IM**; for reinforced work, Portland, **G**; Am Port, **CS, BR, Hb, FW**; "Universal" Portland cement, **SE**; cem made by mfr of established reputation (in successful operation not less than 2 yrs, **F**), brand in continuous successful use (in America, **F**) for the last 5 yrs (3 yrs, **CS**) **G**; in satisfactoryuse in similar quantities by U.S. Engr Dept at Large, **TR**; of tried uniformity, in use not less than 3 yrs in similar climate, **CR, Hb**; only one brand to be used, **G**; except for good reasons, **F**; only one brand in any monolith, **FP**. Portld in reinfd work and where subject to shocks or vibrations or to stresses other than direct comp; nat in massive work where weight is more important than strgth, and where economy is the governing factor; puzzolan only for foundations underground, not exposed to air or to running water, **JC**.

2. Requirements. For Strengths, etc., see Digest of Specfn for cem, by A S T M, p 940, Report of Board of U. S. Engr Officers, Prof'l Papers No 28, Corps of Engrs, U.S.A., '01, p 937, and Digest of Specfn by Engng Standards Comm of Great Britain, p 940. **For tests,** see Digest of Specfn of A S C E, p 942. Slow setting, **FP**; must have been tested ≮ 6 mos, ≯ 12 mos, prior to issue of permit, **L**; must meet requirements of Prof'l Paper No. 28, Corps of Engrs, U.S.A., '01, p 940, **BR, AH, TR, CR, FW, Wv, FP, Hb.**

3. Shipment. Packages to "contain either 380 lbs or some even division of 380 lbs," **Lv**; in cooperage or in cloth bags, **NO**; bag, 93 lbs (94 lbs, **Co**) net, bbl = 4 bags, **NO**; in bbls, lined with paper, **CR, WH**; in cloth bags, **Ci**; may be delivered in paper bags, **Wv.**

4. Storage at site of work. In weather-tight bldg, with floor raised (≮ 6", **T & T**) above ground, **G**; and holding ≮ 2 wks' supply under av conditions of work, **Ci**; cem in bags may be used after 3 mos storage, rejected if it becomes lumpy or otherwise deteriorated within that time, **BR**; cem, kept over winter, re-tested before using, **Wv.**

Sand.

5. General. Silica, hard, clean, sharp, **G.** Reasonably clean, coarse, **F**; water worn, voids = 35 %, **SE.** "Sharpness" purposely omitted, **T & T.** River sand, **Ci, a.**

6. Size. Well graded, with fine, medium and coarse grains, **F, Lv, NO, Co.** Coarse, or coarse and fine, mixed, **CS, T & T.** Coarse predominating; coarse preferred at double or treble cost, **T & T.** Medium, **Ci, a.** Largest to pass screen of ¼" mesh, **G.** ≯ 10 % coarser than ⅛", **NO**; ≮ 50 % retained on No. 30 sieve (holes 0.022" □), **WH.** ≯ 40 % to pass No. 50 sieve (2500 meshes / □"), **Hb.** ≯ 3 % very fine, **NO, Co, Ci, a.** ≯ 5 % very fine, **Bu.**

Foreign matter (clay, loam, sticks). None, **CS, T & T**; ≯ 2 % **NO**, ≯ 3 %, **Co, Lv**; ≯ 5 %, **Wv, OD, TR, CR, Bu.** ≯ 10 % clayey, **AH.** ≯ 3 % clay, etc, ≯ 2 % mica, **FW**; ≯ 4 % free loam, **Hb**; sand may be moist, not wet, **TR**; stored on a board platform, **CR**; or in bins, **Wv.**

7. Screenings. Crusher dust, passing ¼" screen, from broken stone, may be substituted for part or all of the sand, **T & T**; "screenings & crusht stone may be substituted for sand and gravel under special conditions," **F**; screenings permitted, **BR, CR**; if passing ¼" screen, **TR**; screenings preferred to sand, **AH.**

Aggregate ("Ballast").

8. Kind. Sand grit, gravel or broken stone, **BB**; gravel or broken stone, **G**; or both, **BR**; gravel, **Lv**; (see Screenings); sea-washed gravel, **Lp**; water-worn pebbles of igneous rock, **SE**; clean stone, gravel, broken hard bricks, terra cotta, furnace slag or hard clean cinders, **Un**; broken stone preferred, gravel permitted for interior of piers, pedestals and abuts, **WH**; broken stone, **AH.**

For abbreviations, symbols and references, see p 1251

9. Requirements. Clean, hard, durable; free from dust, loam, clay and perishable matter; washed or screened if reqd, **G**: approx cubical, **CS**, **AH**; free from long thin pieces, **BR**, **NO**, **CS**; ≮ 125 lbs/cu ft, **FP**; ≮ 130 lbs/cu ft, **Hb**; voids = 31 %, **SE**; drenched before using, **G**; but not to carry water, **Wv**; kept thoroly sprinkled, **IM**, **Hb**.

10. Sizes, inches: min, ¼, **G**; ⅛, **FW**, **Mc**: max ¾, **Un**: 1½, **Bu**; 2, **G**; 2½, **Hb**; 3, **NO**, **Co**, **Ci**, **a**, **FP**, **SE**: gravel, 3, **F**; stone, run of crusher, **F**, **Mc**, **AH**; 1 to 2½, according to grade of work, **AH**; for foundations, 2; for superstructure, 1½; for beams, cols and girders, 1, **L**; gravel, ≮ 90 % over 1½, ≯ 10 % sand, **Hb**.

	1 cubic foot of stone, gravel or sand grit contained					
Agg	cu ft	lbs	cu ft	lbs	cu ft	lbs
Stone;.. . coarse,	0.63	53.8;	fine, 0.33	30.4;	dust, 0.11	11
Gravel;. . pebbles, ⅜″,	0.80	81.5;	sand, 0.29	29.2;	...	..
Sand grit; gravel, ⅛″ to ¼″,	0.47	47.2;	sand, 0.59	59.3;	.	..

BB.

11. Storage. Stored on wooden platforms, **CR**, **Wv**; or in bins, **Wv**.

12. Cinder concrete. Allowed only for floors, roofs and filling, **Ms**. Reinfd cinder conc to be used only upon special permit of Inspector of Bldgs, **L**.

13. "May be used for all bldgs in which fireproof construction is mandatory by this Chapter, or where ordinary constr, mill constr or slow burning constr may be used," not for cols, piers or walls. Clean, thoroly burnt steam-boiler cinders; mix, Port cem, not poorer than 1 : 7. Cinders must pass 1″ sq mesh, **Ch**.

14. "All other special requirements and methods of calculation for reinfd conc as reqd in this Chapter shall modify and regulate the use of cinder conc in bldgs," **Ch**.

15. Large Stones.
Hard, sound, durable, as large as can be conveniently handled; washed clean; placed wet; one dimension ≮ 12″; no dimension less than 4″; no stone less than 2″ from faces exposed in finished work, conc joggled into place with light rammers, **Co**.

16. ≯ 100 lbs, ≮ 3″ from forms or from other large stones. (From Specfn for a Soldiers' Home.)

17. Permitted in walls > than 18″ thick, diam ≯ quarter of the thickness of wall, vol of stone ≯ one-fifth vol of wall, **Yo**.

18. One-man stones and larger, roughly cubical; long flat pieces to be broken or rejected; stones somewhat uniformly scattered thruout the work; ≮ 8″ apart, ≮ 2 ft from crest or down-stream face; dropped separately into bed of wet conc, pounded down if necessary; if necessary, conc spaded under and around the stones; each stone to be covered with conc before other stones are deposited. Use as many stones as possible without violating these conditions, **Mc**.

19. "Plums." Stones, from one-man to several tons (sometimes from old masonry), aggregating abt 30 % of the finished work ≮ 1 ft from wall surf. Set in top layer of conc and so as to form bond with next layer by projecting upward into it, **Lp**.

20. Proportions, see pp 1254 to 1258.

Measurement of Ingredients.

21. Cem measd "as if compacted so that 380 lbs of dry Port shall have a vol of 3.8 cu ft," **Lv**; cem measd loose, **CS**, **WH**; 1 bag cem ≮ 93 lb = 1 cu ft, **NO**, **Ci**. Cem measd as packt by mfr, **OD**, **L**, **T & T**. Sand and agg measd as thrown loosely into measuring box, **G**. All measd loose, **CS**, **WH**; 100 lbs cem considered to occupy the vol of 1 cub ft, **F**.

Consistency.

22. In general, "very wet," **NO**; water to come to surf with moderate ramming, **CS**; without serious quaking, **OD**, **TR**; sufficiently fluid to require no ramming, **Mc**; little or no tamping, **Hb**.

For lists of Specifications for Concrete, see pp 1352, 1353.

In order to compare intelligently the requirements of diff specfns, the character of the work involved must of course be taken into account.

DIGEST.

Cement.

1. Brand. Portland or natural, **NY**; Port just under lower miter sill, nat elsewhere in foundations, Port in lock walls except for a backing, 2 ft deep, at base, Port and nat bonded together, **IM**; for reinforced work, Portland, **G**; Am Port, **CS, BR, Hb, FW**; "Universal" Portland cement, **SE**; cem made by mfr of established reputation (in successful operation not less than 2 yrs, **F**), brand in continuous successful use (in America, **F**) for the last 5 yrs (3 yrs, **CS**) **G**; in satisfactory use in similar quantities by U.S. Engr Dept at Large, **TR**; of tried uniformity, in use not less than 3 yrs in similar climate, **CR, Hb**: only one brand to be used, **G**; except for good reasons, **F**; only one brand in any monolith, **FP.** Portld in reinfd work and where subject to shocks or vibrations or to stresses other than direct comp; nat in massive work where weight is more important than strgth, and where economy is the governing factor; puzzolan only for foundations underground, not exposed to air or to running water, **JC.**

2. Requirements. For Strengths, etc., see Digest of Specfn for cem, by A S T M, p 940, Report of Board of U. S. Engr Officers, Prof'l Papers No 28, Corps of Engrs, U.S.A., '01, p 937, and Digest of Specfn by Engng Standards Comm of Great Britain, p 940. **For tests,** see Digest of Specfn of A S C E, p 942. Slow setting, **FP**; must have been tested ≮ 6 mos, ≯ 12 mos, prior to issue of permit, **L**; must meet requirements of Prof'l Paper No. 28, Corps of Engrs, U.S.A., '01, p 940, **BR, AH, TR, CR, FW, Wv, FP, Hb.**

3. Shipment. Packages to "contain either 380 lbs or some even division of 380 lbs," **Lv**; in cooperage or in cloth bags, **NO**; bag, 93 lbs (94 lbs, **Co**) net, bbl = 4 bags, **NO**; in bbls, lined with paper, **CR, WH**; in cloth bags, **Ci**; may be delivered in paper bags, **Wv.**

4. Storage at site of work. In weather-tight bldg, with floor raised (≮ 6", **T & T**) above ground, **G**; and holding ≮ 2 wks' supply under av conditions of work, **Ci**; cem in bags may be used after 3 mos storage, rejected if it becomes lumpy or otherwise deteriorated within that time, **BR**; cem, kept over winter, re-tested before using, **Wv.**

Sand.

5. General. Silica, hard, clean, sharp, **G.** Reasonably clean, coarse, **F**; water worn, voids = 35 %, **SE.** "Sharpness" purposely omitted, **T & T.** River sand, **Ci, a.**

6. Size. Well graded, with fine, medium and coarse grains, **F, Lv, NO, Co.** Coarse, or coarse and fine, mixed, **CS, T & T.** Coarse predominating; coarse preferred at double or treble cost, **T & T.** Medium, **Ci, a.** Largest to pass screen of ¼" mesh, **G.** ≯ 10 % coarser than ⅛", **NO**; ≮ 50 % retained on No. 30 sieve (holes 0.022" □), **WH.** ≯ 40 % to pass No. 50 sieve (2500 meshes / □"), **Hb.** ≯ 3 % very fine, **NO, Co, Ci, a.** ≯ 5 % very fine, **Bu.**

Foreign matter (clay, loam, sticks). None, **CS, T & T**; ≯ 2 % **NO**, ≯ 3 %, **Co, Lv**; ≯ 5 %, **Wv, OD, TR, CR, Bu.** ≯ 10 % clayey, **AH.** ≯ 3 % clay, etc, ≯ 2 % mica, **FW**; ≯ 4 % free loam, **Hb**; sand may be moist, not wet, **TR**; stored on a board platform, **CR**; or in bins, **Wv.**

7. Screenings. Crusher dust, passing ¼" screen, from broken stone, may be substituted for part or all of the sand, **T & T**; "screenings & crusht stone may be substituted for sand and gravel under special conditions," **F**; screenings permitted, **BR, CR**; if passing ¼" screen, **TR**; screenings preferred to sand, **AH.**

Aggregate ("Ballast").

8. Kind. Sand grit, gravel or broken stone, **BB**; gravel or broken stone, **G**; or both, **BR**; gravel, **Lv**; (see Screenings); sea-washed gravel, **Lp**; water-worn pebbles of igneous rock, **SE**; clean stone, gravel, broken hard bricks, terra cotta, furnace slag or hard clean cinders, **Un**; broken stone preferred, gravel permitted for interior of piers, pedestals and abuts, **WH**; broken stone, **AH.**

For abbreviations, symbols and references, see p 1251.

(2) Stone shoveled upon mixture of cem and sand. In (1) or (2), turn 3 times, adding water in first turning.

(3) Mixture of cem and sand made into mortar and spread upon stone. Mass of mortar and stone turned twice, **T & T.**

32. In any case, result must be a loose conc of uniform color and appearance, stones thoroly incorporated into mortar. Consistency uniform thruout, **T & T.**

33. "As the gravel box was being filled, the cement was added to it gradually, so that, when the gravel box was full, the cement box was empty. The box was then removed, and the heap leveled off to a uniform thickness of ≯ 1 ft, and was then mixed by casting backward and forward twice," water added at time of second casting, **Lp.**

Forms.

34. Lagging. Of well seasoned boards, 2″ thick, drest all over, tongued and grooved, **Co, b;** 2″ × 6″ pine, drest on all sides, **Hb:** boards planed on one side and two edges; one edge slightly beveled and placed against the square edge of the next plank, **Yo;** boards preferably 2″ × 6″, dressed-and-matched flooring, **WH;** forms for exposed faces, of planed lumber, tongued and grooved or beveled; wall forms to be braced, and, where possible, to have their sides wired together, **Ci;** butt joints square, and either on posts or reinfd, **Hb;** joints, showing spaces, to be filled with stiff clay immedy before placing conc, **Hb.**

Used lagging, if not scarred, may be used again; but, for exposed work, must be cleaned and oild, **Hb.**

Posts. Generally 3″ × 8″ pine, drest on both edges, of full height of wall, ≯ 4 ft apart, **Hb.**

Centers and forms to be wet, **IM;** if reqd, before laying, **NO, Ci, b;** or oiled, **NO.** According to circumstances, forms to be wetted (except in freezing weather) or greased with crude oil, before placing conc, **T & T;** oild just before use, **Hb:** painted or oild before re-using, **CR;** dampend just before placing conc and kept damp until work has hardened, **TR, Wv.**

For removal of forms, see p 1191.

35. On up-stream face of dam, molds need be only smooth enough to give good substantial work, free from voids. On crest and down-stream face, molds must have planed surfs, so as to leave the finished work smooth, **Mc.**

36. Tie rods, left in conc, must not come nearer to conc surf than 2″, **CR;** projecting ends of iron bolts and rods to be cut off smooth and flush with conc face, **BR, AH;** not chiseled, but sawn or otherwise removed without jarring the work, **AH;** aids for holding molds not to be inserted within 4 ft of top of walls, **BR;** no bolts, etc, to show in the completed work, **OD.**

Placing, Churning and Ramming.

37. Night work prohibited in general, **TR. Time of placing;** conc must be placed within 30 mins after mixing, **AH, NO, Ci, b;** ≯ 30 mins "betw wetting the cem and the undisturbed conc in final place," **F;** before initial set, **TR, OD, CR, Wv, FW, Hb, Bu;** after mixing, mass kept in motion until placed in vehicle for transportation, **TR.** No **retempering** or rehandling permitted, **TR, CR, NO, Bu, Co, Ci,b, JC.** Conc, in which the materials have separated, must be remixt (by hand mixing, **BR, AH**): before laying, **T & T.**

Manipulation. In very wet conc, air must be churned out, stones workt back from face, and conc workt **under rods,** etc., **G;** by means of thin steel or iron blades, about 4″ × 6″, with handles of adjustable length, so that workmen need not stand in conc, **NO, Ci,b.** Conc to be joggled or worked into place by light ramming, **Bu, Co;** ram until mortar comes to surface, **AH, BR;** until all voids are filled and water flushes to the surf, **CS;** one tamper to not more than 2 cu yds per hr, **BR;** rammers with striking area not less than 36□″, weighing not more than 10 lbs, **Co;** face 6″ sq, weight, with handle, about 20 lbs, **CR;** 30-lb iron-shod rammers, face area not more than 30□″, **IM;** 40-lb rammers, **SE;** conc placed without ramming, **FP.**

For lists of Specifications for Concrete, see pp 1352, 1353.

38. Dry conc moistend by sprinkling, not pouring, **CR.**

39. Conc must be continuously **worked around reinfmt,** with uitable tools, as put in place. Complete filling of forms, and subsequent uddling, prohibited. Partly set conc must not be subjected to shocks, **Ch.**

40. Placing, in layers. Care taken to remove all scum, arising rom the cem, before laying the next layer, **Lp, JC.**

41. Conc **dumped** from receiving box or car, or shoveled directly into lace, use of slides and shutes forbidden, **OD, Wv, FP, TR, CR;** not ropt further than 6 ft, **FP;** 3 ft, **Wv.**

42. No walking on finished wall until set, **OD, Co.**

43. Thickness of layers. Not over 6", **Wv, BR, OD;** about ", **CR;** about 6" after ramming, **TR;** 6 to 8", **CS;** ≯ 6", **F;** ≯ 4", **SE;** ith dry mix, on slopes, ≯ 4", **F;** ≯ 4" in foundations, about 6" in back alls, **IM;** ≯ 9", **Hb;** ≯ 12", **WH;** such that each layer can be incororated with the preceding one, **T & T.**

44. No layers permitted, **Bu, Co;** layers not run out to thin edge, **FP;** ach layer completed (rammed, **CR**) before the next is laid, **FP, CR;** ach layer of a day's work laid before the layer next below has set, **TR.**

45. On rock foundation. Rock cleaned and washed with wire rooms, roughened if reqd, covered with thick neat cem grout, **CR;** bed wet mortar, **FW;** ½" thick, **TR;** conc anchored to rock with steel rods, reqd, **CR.**

Joints.

46. Avoidance of horizontal joints. Walls, etc, built in alterate sections, so short that they can be constructed as monoliths; these ections keyed together by vertical tongue-and-groove joints, **G** for gov't pecfns; joints continuous from foundation to coping, **CR;** "joints shall be ormed betw adjoining sections of conc for 4 ft down from the deck, by a yer of tarred paper," **BR;** dovetailing to have a thin coat of mortar, 1 : 5 weaker, to set before new conc is placed against it, **Hb.**

47. Joints between old and new work. Exposed surfs shaded nd kept moist until work is resumed, **CR;** chipped or broken edges cut way, **CR;** old surf to be left stepped, to form bond, and to be cleaned and et before adding new work, **FW, G;** cleaned with stiff wire brush and ream of water, **FP, BR, Hb;** if reqd, **F, Lv;** roughed up with a pick, reqd, **BR;** wooden strips, 4 to 6" wide, with beveled sides, to be embedded 3", and removed before conc has thoroly hardened, **NO;** between old and ew work, bed of 1 : 3 cem mortar 1" thick, **NO, Co;** ½" layer of mortar, **P;** old surf covered with neat cem grout of molasses consistency, **BR;** or y cem, **OD;** dry cem, brushed in, **Hb;** with layer of mortar, **TR, W;** old surf mopped with 1 : 2 mortar, **CS;** with heavy neat cem grout orked into surf with brooms, **CR;** keyed as directed, **FW.**

48. In hor joints in thin walls, or in walls to sustain **water pres,** in other important locations, mortar joint may be reqd. Tanks, etc, ith thin walls to hold water, should be built as monoliths, without interption, the work proceeding, if necessary, night and day, **T & T.**

49. When work is suspended for more than an hour, the outer lges of the last layer are to be leveled, and the center portion of the surf to be left about 6" lower than the edges, **CR.**

50. Bond betw new conc and old wall. Dovetailed pockets, 24" wide at ce, 33" at back, 15" deep, cut vert in old masonry, 4 ft apart, **Lp.**

51. Last layer deposited to be left as rough as possible, imbedded boulds projecting. Surf to be cleaned, washed, and sprinkled with neat cem, **c.**

Placing under Water.

52. Under water. No conc to be laid under water (without explicit rmission, **F;** except to stop leaks and springs, **TR;**) water not allowed rise on new work until thoroly set, **IM, Wv, TR, OD;** not less than hrs after set, **Lv, NO, Co, Cl,b;** if placed under water before setg, mixture to be 1 : 2 : 3, **WH;** 80 % of work built in place below (fresh) ater level, **SE;** conc, placed in water, must be semi-dry, **Ph;** bags to be wered to within a few ins of surf on which conc is to be deposited, **FW.**

For abbreviations, symbols and references, see p 1251.

53. When forms extend down to below high water, leaks under forms to be stopped, in order to prevent undermining before set; bags, filled with sand, placed outside; or jute canvas, underlying the conc 12″, nailed along bottom of form on the inside, **FW.**

Rain.

54. Rain. During rain storms, no new work to be laid, **IM, Bu, CR, AH, FP;** freshly laid work to be protected by canvas, **Bu.**

Frost.

55. Freezing. No concrete or mortar to be made when temp is below 35° F. in shade; conc work stopped from Nov 20 until April 1; during freezing weather, no conc to be mixed or deposited without engineer's consent, **IM, Bu:** ice and frost to be removed, water and sand heated, gravel steamed, work covered and kept warm by steam pipes, **Lv:** conc not to be placed when frozen, if reinfd, must be kept above 32° F for $\nless$ 48 hours after placing, use of frozen sand and agg prohibited, **Ch.** No laying permitted when temp $\ngtr$ 32° F., **Un, AH, BR,** < 32° F, **OD:** < 30° F, **CR,** < 34° F., **TR, FP;** when likely to freeze before set, **Wv:** before final set, **OD;** before set sufficiently to prevent injury, **BR, CR.** Conc, frozen in place, to be removed, **Un.** No conc to be laid when temp is below 20° F; water to be heated when temp is below 35° F, **Mc.** Use of icy materials prohibited; placed conc must be protected against freezing, **Ph.**

56. Natural cement concrete must never be exposed to frost until thoroly hard and dry, **T & T.**

57. "No conc, except that laid in large masses, or heavy walls having faces whose appearance is of no consequence, shall be exposed to frost until hard and dry. Materials employed in mass conc in freezing weather shall contain no frost. Surfs shall be protected from frost Portions of surf conc, which have frozen, shall be removed before laying fresh conc upon them." **T & T.**

58. Forms, under conc placed in freezing weather, "**to remain** until all evidences of frost are absent from the conc, and the natural hardening of the conc has proceeded to the point of safety." **Ch, Ph.**

Moistening.

59. Moistening. Freshly laid conc to be protected from the sun (by boards or tarpaulins, **FP, Hb, IM;**) and kept wet, **Mc, IM;** $\nless$ two weeks, or until covered with earth, **F;** $\nless$ 10 days, **SE, AH;** 6 ds, **CR:** 3 ds, **FW;** 48 hrs, **BR;** until set, **Wv;** until hard set, **Hb;** unfinished surfs until work can be resumed, **CR;** with wet tarpaulins $\nless$ 3 days, **CR.** When a section of wall is completed, coping to be covered with a thick layer of wet sand, mass of wall kept sprinkled until conc is thoroly set, **IM;** conc to be drenched twice daily, Sundays included, for a week after placing, in hot weather, **Ch, Ph.**

60. Moisten by sprinkling with fine spray at short intervals or by covering with moistened burlap, or etc, **G.**

Removal of forms.

61. Forms must be left in place $\nless$ 4 days, **IM;** $\nless$ 7 ds; longer if reqd by engineer, **Lv;** 72 hrs, **OD;** 48 hrs, **AH, BR;** until conc has stood at least 36 hrs, **WH;** until removal is authorized by engineer, or until conc has become hard, **Cl,b;** until conc can carry its load safely, **Ms;** forms removed after 48 hrs, **SE.**

62. Props, under floors and roofs, to remain in place $\nless$ 2 weeks. Forms, for cols, $\nless$ 4 days; for slabs, beams and girders, $\nless$ 1 wk and at least until the floor can sustain its own weight. "No load or wt shall be placed on any portion of the constr where the said centers have been removed." **Ch, Ph.**

63. Time for removal of forms and centering, 24 hrs to 60 days, depending upon temp and other atmospheric conditions and upon the commissioner of bldgs, **Un.**

For lists of Specifications for Concrete, see pp 1352, 1353.

64. Not until conc is hard.

	Min time, days:	
	Apr 1 to Dec 1	Dec 1 to Apr 1
Slabs and lintels, cols and monolithic walls	10	15
Posts and bottom supports for joists, beams and girders	14	21 **L.**

65. Forms, under conc placed **in freezing weather,** "to remain until all evidences of frost are absent from the conc and the natural hardening of the conc has proceeded to the point of safety." **Ch, Ph.**

Surface finish, waterproofing, etc.

66. Finish kept smooth by manipulation during placing, not by subsequent plastering, etc. Conc, free from large agg, to be placed next the mold, and prest back from mold by means of a flat shovel, inserted betw conc and mold (mold sprinkled with water, **BR**), conc rammed with an iron rammer, lower face 2″ × 6″, **AH, BR**; finish by working gravel back from face by means of forks, **Hb**; or shovels, **FP**; faces rubbed smooth, **TR, Hb**; with a piece of wood or soft stone, **TR**; voids filled up with mortar, **Hb, TR, CR**; plastering permitted only for an occasional and accidental cavity where the plastering is not apt to be disturbed by frost, **CR.** See p 1361, ¶ 79. 1 : 3 Port cem mortar, placed simultaneously with backing, **CR.** For wall, 1 : 2 Port cem mortar, very dry, 1½″ thick, **TR.**

67. For exposed faces, forms to be removed before conc has hardened; surf (1) rubbed with mortar of 1 vol Port cem, 2 vols sand, applied with a burlap swab and brushed down with a plasterer's brush, or (2) rubbed with stiff wire brush and a thin coat of neat Port cem grout, brushed down with plasterer's brush, **NO, Co**; smooth finish of sides produced by thoro ramming against inside surfs of molds, **SE.**

68. Surfs, not built against forms, screeded and troweled to smoothness, **NO.**

69. Voids or other imperfections, appearing upon removal of forms, to be corrected at expense of contractor, who shall remove and replace unsatisfactory work if reqd, **F.**

70. For floors and roof of mixing tank. Stiff mortar, of 1 vol Port, 1 vol sharp stone screenings to pass ⅜″ ring, free from dust, loam, etc, 1″ deep, laid before conc has initial set. Screeded, floated and troweled to smooth surf. Covered and sprinkled 3 days, **Co.**

71. Promenades and tops of parapets finished with a layer of mortar $\ngtr$ ¼″ thick, consolidated with the conc "by superimposing heavy planks 4″ thick and ramming them with 40-lb cast iron rammers until their ends are in contact with the ends of the molds," **SE.**

72. For piers, pedestals, abutments. Surfs exposed to air or water, 1½″ Port cement mortar, 1 cement, 2 sand, carried up simultaneously with the conc, 10 or 11″ in depth at a time, by means of ¼″ steel plate forms, 12″ wide, 4 to 5 ft long, placed around the work, 1½″ from the forms, and blocked out every 12″ by wooden blocks, the ends of the plates lapping slightly, **WH.**

73. For inverts, 1 cem, 2 sand, not more than ½″ thick, laid at same time as conc, **Lv.**

74. Moldings, cornices, etc. Plastic mortar placed against finely constructed molds, as conc is being laid; no exterior plastering permitted, **SE, T & T**; no plastering to be done unless expressly permitted, **F.**

75. Top finish. Conc brought up to 3½″ from reqd elevation; while this is still unset and plastic, 3″ of finer conc added, tamped and kneaded to form a monolith with the underlying conc; then ½″ of 1 : 3 (1 : 2, **AH**) cem mortar added and worked down to reqd grade by rubbing with a long wooden straight-edge, **AH, BR.**

76. Coping. While conc base is still soft, unset and adhesive, mortar (to be 1″ thick when finished) spread, leveled off and beaten with wooden battens or mauls; floated with wooden float and smoothed with plasterer's trowel; covered with boards or tarpaulins until hard set; then covered with sand; to be kept damp several days, **FP**; mortar, $\nless$ 1″ thick, of 375 lbs Port cem to 10.5 cu ft sand; tamped in place on top of rammed conc before the latter has begun to set; raked with straight-edge, rubbed with wooden

For abbreviations, symbols and references, see p 1251.

floats and finished with plasterer's trowel, **CR**; 1 : 2 Port cem mortar, 1″ thick, **TR**; surf formed by working the stones back from face, **Hb.**

77. **Granitoid surface finish** for tops of piers, pedestals and abuts; 1 part Port, 2 parts clean coarse granite sand or fine granite screenings, 3 parts granite chips, passing ½″ iron ring. Finished with a floated surf. **WH.**

78. **Water-proofing.** Heavy coat of semi-liquid mortar 1 part cem, ¼ part slaked lime, 3 parts sand. This coat to be given a smooth finish. When this has set hard, add a heavy coat of pure cem grout, **CS.**

79. **Plastering with cement.** None permitted on exposed faces, **AH, CS.** Inside faces of spandrel walls, covered by fill, to be well dampened and plastered with mortar of 1 cem : 2.5 sand, **CS.** See p 1360, ¶ 66.

Artificial stone.

80. (a) **For fine moldings, etc.** Molds plastered with semi-liquid mortar, 1 cem, 2 fine sharp sand, backed with earth-damp conc 1 : 2 : 4, or 1 cem to 6 gravel passing ¾″ ring. Conc backing rammed in thin layers. (b) **For plain flat surfaces.** Conc rammed in mold. Mold removed. Exposed surfs floated to smooth finish with mortar as in (a). No body of mortar to be left on face. Use only enough to fill pores and give smooth finish, **CS.**

Strength, etc, required.

(Strengths, etc, in lbs / □″, unless otherwise stated.)

81. **Ultimate comp,** after hardening for 28 days, ≮ 2000, **Un, Mh.**

82. **Ult shear** corresponding to 2000 comp, 200, **Un.**

Maximum allowable loads.

83. **For static loads** upon a 1 : 6 Port cem conc.

	Max allowable load lbs / □″†	
Compressn, conc surface > loaded area	0.325.s*	= 650
" in columns, length ≯ 12 diams	0.225.s	= 450
" " " with longitudinal reinfmt only	0.225.s	= 450
" " " hooped	0.270.s	= 540
" " " " , with 1 to 4 % long'l bars	0.325.s	= 650
" " " with structural steel col units thoroly encasing conc core	0.325.s	= 650
Rupture modulus (elas mod, E, constant)	0.325.s	= 650
" " adjacent to supports, (E constant)	0.375.s	= 750
Pure shear (no comp normal to shearing surf; reinfmt taking the normal tension)	0.060.s	= 120
Shear, combined with equal comp	0.162.s	= 325
Adhesion, plain bars	0.040.s	= 80
" drawn wire	0.020.s	= 40

twisted. **Co**; Ransome twisted square preferred, **F**; Ransome or equal, **Hb**; Thacher bar, **CS**; square, twisted cold, or Johnson corrugated bar; in Johnson bar, net section = that reqd, by the plans, for twisted bars; plain bars to be used in comp only, **Cl.**

98. Twisted bars.

Size, ins	¼	⅜	½	⅝	¾	⅞	1	1⅛	1¼	
Twists per ft.....	12	8	5	3.5	2.5	2	1.75	1.5	1.5,	**NO, Co**;
	6	...	...	...	...	...	1.5	...	...,	**Cl.**

One turn in 5 to 7 times nominal size, **F.**

Twisted uniformly by machinery; min cross sec area to vary not more than 2.5 %, **NO, Co.**

99. Round, corrugated, etc, bars to have same agg net sec area as square or twisted bars, **NO.**

Requirements.

100. Iron and steel "to meet the 'Manufacturers' Standard Specfns,' revised Feb 3, '03," **Ph.** See pp 1154, 1155.

101. Steel. Mfr and hardness. Medium open-hearth, **NO, Bu, Co, Cl**; mild, **Lv**; soft or medium, **CS.**

102. Ultimate tensile strength, in thousands of lbs / □″. 52 to 62, **F**; 54 to 64, **Un, Mh**; medium, 50 to 65, **Cl,a**; medium, 60 to 68, **CS**; soft, 54 to 62, **CS**; 55 to 65, **Lv, T & T**; ≮ 55, **NO**; 57 to 65, **Co,a**; 60 to 70 before twisting, **Co,b**; 60 to 70, **Bu.**

103. Ult comp strength.

Mixture		1:1:2	1:1.5:3	1:2:4	1:2.5:5	1:3:6
lbs/□″	=	2900	2400	2000	1750	1500
$n = E_s / E_c$	=	10	12	15	18	20

Ch.

104. Fracture, silky, uniform in color and texture, **Co.**

105. Elastic limit ≮ half ult tensile strgth, **G.**

106. Elastic modulus, 30,000,000 lbs/□″, **CS.**

107. Ratio, n, of elastic moduli. $n = \frac{E_s}{E_c} = \frac{\text{elas mod for steel}}{\text{elas mod for conc}}$.

n = 12, **Mh.** "If not shown by direct tests," in beams and slabs, n = 15; in cols, n = 10, **Ms**; with ult comp strgth = 2000 lbs / □″, n = 18, **Un.** Stone or gravel conc, n = 12; slag, n = 15, **Ph**; cinder, n = 30, **Ph, Ch.**

108. Elongation. %, minimum, in 8″, 25, **F, Lv, NO, Co,a**; 22, **Co,b, Cl,a**; 20, **Un, Mh**; soft, 25; medium, 22, **CS**; $\frac{1,400,000}{\text{tensile strgth}}$, **T & T.**

109. Bending test. Cold, **F, Lv, Bu, CS**; hot, cold or quenched, **NO, Co,a**; 180° about a diam = the thickness of the bar, **F, NO, Bu, Co, CS**; (before deforming, **F**); about a diam = twice the thickness of the bar, **Lv**; (after deforming, **F**); soft steel, flat, **CS**; cold, 90° over a diam = twice the thickness of the bar in steel ≯ ¾″ diam; over a diam = 3 × thickness of bar in steel > ¾″ diam, **Ch.**

Maximum stresses allowed in steel.

Stresses in lbs / □″ unless otherwise stated.

110. Tension, 16,000, **Mh, Ph, JC**; (iron, 12,000, **Ph**); one-third elas lim, but not over 18,000, **Ch**; mild, 12,000; medium, 15,000; high-carbon, 18,000, **L.**

111. Shear, 10,000, **Mh**; 12,000, **Ch.**

112. Comp = comp in conc × $\frac{\text{elas mod in steel}}{\text{elas mod in conc}}$, **Ch.**

"In arches, the steel ribs under a stress not exceeding 18,000 lbs per square inch must be capable of taking the entire bending moment of the arch without aid from the conc, and have flange areas of ≮ the 150th part of the total area of the arch at crown. The actual stress when imbedded in and acting in combination with conc shall not exceed 20 times the allowed stress on the conc."

For lists of Specifications for Concrete, see pp 1352, 1353.

"In slabs, girders, beams, floors, and walls, subjected to transv stress, the steel shall be assumed to take the entire tensile stress without aid from the conc, and shall have an area sufficient to equal the comp strgth of conc composed of 1 part Port cem, 3 parts sand, and 6 parts of broken stone, of the age of 6 mos."

"In walls or posts subjected to comp only, no allowance will be made for the strgth of imbedded steel, which will be used only as a precaution against cracks due to shrinkage or changes of temp."

"In tanks, the imbedded steel under a stress not exceeding 15,000 lbs / □" shall be capable of taking the entire water pres without aid from the conc," **CS.**

Elongation in service not more than 0.2 %, **Ch.**

113. Adhesion between steel and concrete. Assumed ⋟ allowed shear on conc, **Mh, Ms;** ⋞ shear on conc, **Un;** in stone or gravel conc, 50 lbs / □"; slag, 40; cinder, 15, **Ph.**

114. In 1 : 2 : 4 conc, max, lbs / □":

on plain round or square bars, structural steel	70	
high carbon steel	50	
on plain flat bars, ratio of sides ⋟ 2 : 1	50	
on twisted bars, ⋞ 1 twist in 8 diams	80	
on specially formed bars, 0.25 × ult adhesion as determined by test; max	= 100	**Ch.**

115. When the allowed adhesion is exceeded, "provision must be made for transmitting the strgth of the steel to the conc," **Un, Mh, Ph.**

116. Length and lapping.

Longitudinal bars **not less than 30 ft,** if possible, **Lv.**

In beams, rods of **single length,** if possible, **NO, Co, Ci.**

If lapped

Size of rod, ins	¼	⅜	½	⅝	¾	⅞	1	1⅛	1¼	
Lap, ins	6	10	13	18	20	22	26	30	32	**NO.**
	6	9	12	15	18	20	22	24	27	**Co.**

Lap = 25 diams of rod, **Bu.**

Lap ⋞ 20 × diam of rod, ⋞ 1 foot, **Ci.**

In parallel rods, **joints staggered, Bu, Ci.**

Ends, not less than 2" from any surf, **Lv.**

Rods extend to extreme edges of unfinished surfs.

" " " within 1" of finished surfs. **Co.**

Floor rods extend 4" beyond face of wall supporting the floor;

Beam " " ⋞ 8" beyond face of wall supporting the floor, **NO, Ci.** See Clearance, below.

117. Protection. If work is interrupted, bars, already placed, must be protected, as with canvas or tarred paper. Ends, projecting for a considerable time, to be painted with heavy coat of neat cem grout, **F, Lv.**

Permit.

118. Complete detailed plans and specfns, giving composition of conc, to be filed with the Commissioner of Bldgs, **Ch, Un, Mh, Ph.**

Issue of permit does not involve acceptance of constr, **Ch.** For tests required, see pp 1362–3.

Clearance. See also ¶¶ 116, 134, 144, 149.

Distance, t, between steel and surf of conc.

119. In cols, beams and girders, t ⋞ 1½", **Ch, Ms;** in slabs, t ⋞ ½" ⋞ diam of bar, **Ch;** t ⋞ ¾", **Ms;** t ⋞ 1.5 × diam of bar, **JC.**

Axis of rods dist from outside of conc ⋞ diam of rod, **CS.**

For fireproof buildings, see ¶¶ 120–128.

Clear dist betw bars ⋞ 1.5 × max sectional dimension of bar, **Ch, JC. Clear dist betw two layers of bars,** ⋞ ½", **JC.**

120. For fireproof buildings (¶¶ 120–128), reinfd conc constr not approved "unless satisfactory fire and water tests shall have been made under the supervision of this Bureau," **Mh.**

May be accepted if designed as prescribed in code, provided that:

(1) Agg shall be "hard-burned broken bricks, or terra-cotta, clean furnace

For abbreviations, symbols and references, see p 1251.

clinkers entirely free of combustible matter, clean broken stone, or furnace slag, or clean gravel, together with clean siliceous sand, if sand is reqd to produce a close and dense mixture;" **Un.** (The other codes quoted specify fewer permissible varieties of agg.) Agg to pass ¾ in sq mesh, **Ch**; 1" ring, and 25 % of agg ≯ half max size, **Ph.**

(2) Min thickness, t, of conc, surrounding the reinfg members, shall be as follows, where d = diam parallel to t:

121. When $d \not> \frac{1}{4}''$, $t = 1''$; when $d > \frac{1}{4}''$, $t = 4\,d$. In any case $t \not> 4''$; $t \not< $ thickness required for structural purposes plus a, $a = 1''$ in cols and girders, $a = \frac{3}{4}''$ in floor slabs "but this shall not be construed as increasing the total thickness of protecting conc as herein specified." **Un.**

122. In girders and columns, $t = 2''$; in beams, $t = 1\frac{1}{2}''$; in floor slabs, $t = 1''$, **JC.**

123. In monolithic cols, the outer 1½" to be considered as protective covering, and not included in effective section, **JC.**

124. For beams and girders; on bottom, $t = 2''$; on sides, $t = 1\frac{1}{2}''$. Under slab rods, $t = 1''$. In cols, $t = 2''$, **Ch, Ph.**

125. "If a supplementary metal fabric is placed in the conc surrounding the reinfg, simply for holding the conc, the thickness of conc under the reinfg may be reduced by ½", such fabric shall not be considered as reinforcg metal," **Ch.**

126. On floor and roof beams, $t = 1''$; on floor and roof girders, and on beams carrying masonry, on top, $t = 1''$; elsewhere, 2", on cols, carrying only floors, $t = 3''$, on cols built into or carrying walls, 4", **Ms.**

127. Cinder concrete, for fireproof constr, t same as for stone conc; for slow-burning or mill constr, on cols, $t = 2''$; "on beams, girders and other structural steel or iron members," $t = 1\frac{1}{2}''$. Covering to have "metal binders or wire fabric imbedded in and around" such members; binders, if of wire, not less than No. 8, not less than 16" apart, **Ch.**

128. Corners of cols, beams and girders, to be beveled or rounded, **JC.**

Columns.

129. Columns must be allowed ≮ 2 hrs for settlement and shrinkage before girders are constructed over them, **JC.**

130. "**Rules** for the computation of reinfd conc cols may be **formulated from time to time** by the bldg commissioner with the approval of the board of appeal," **Ms.**

131. Concrete and steel assumed to shorten "in the same proportion", **Ms.**

132. Conc and steel stressed in ratio, n, of their elastic moduli, **JC.**

133. Rods tied together at intervals sufficiently short to prevent buckling, **Ms.** See ¶ 136.

134. Outer 1½" to be considered as protective covering and not included in effective section, **JC.**

Reinforced columns.

L = length; d = diameter or least side.

135. Reinfd conc may be used for cols when $L \not> 12\,d$, **Ch, Un, Mh;** $\not> 15\,d$, **JC;** and where cross section area ≮ 64 □", **Ch.** If $L > 15\,d$, allowable stress to be decreased proportionally, **Ph.**

136. Requirements. Rods to be tied together at intervals not more than d, **Un, Mh, Ph;** not more than 12 d, not more than 18", **Ch.** See ¶ 133.

137. Longitudinal rods not considered as taking **direct compression, Ph.**

138. Combined **cross section area** of comp rods ≯ 3 % of cross sec area of col, **Ch.**

139. When comp rods are not reqd, combined cross sec area of rods to be ≮ 0.5 % of cross sec area of col; not less than 1 □", **Ch.**

140. Least dimension of smallest rod to be not less than ½", **Ch.**

For lists of Specifications for Concrete, see pp 1352, 1353.

141. Rods to extend into the col above or below, lapping the rods there sufficiently to develop the stress in the rod by the allowed unit for adhesion, **Ch.**

142. Eccentric or transverse loading. Max fiber stress, including (1) direct comp, (2) bending due to direct comp, (3) eccentricity and (4) transverse load, not more than allowable comp stress. Eccentric load "shall be considered to affect eccentrically only the length of col extending to the next point below at which the col is held securely in the direction of the eccentricity," **Ms.**

143. A column, monolithic with or rigidly **attached to a beam or girder,** must resist, in addition to direct loads, a moment = max unbalanced moment in the beam or girder at the col, **Ch.**

144. Hooped columns. Conc may be stressed to 25 % of ult strgth, provided

(1) Cross sec area of vert reinfmt ≮ area of spiral reinfmt, ≯ 5 % of area within hooping;
(2) Percentage of spiral hooping ≮ 0.5, ≯ 1.5;
(3) Pitch of spiral hooping uniform and ≯ 0.1 × diam of col, ≯ 3″;
(4) Spirals so secured to verticals, at every intersection, as to maintain form and position;
(5) Spacing of verticals ≯ 9″, ≯ 1/8 circumference of col within hooping.

Hooping "may be assumed to increase the resistance of the conc equivalent to 2.5 × the amount of the spiral hooping figured as vert reinfmt." Conc, outside of hooping, not considered as part of effective col sec, **Ch.**

145. "The working stresses will be a subject for special consideration by the Commissioner of Bldgs," **Un.**

146. Allowed unit compression = 1000 lbs/□″ of area within hooping, **Ph.**

147. Percentage of long'l rods and spacing of hoops to be such that the conc may develop this stress with a safety factor of 4, **Ph.**

148. "Hoops or bands not to be counted upon directly as adding to the strgth of the col," **JC.**

149. Clear spacing of bands and hoops ≯ 0.25 × diam of enclosed col, **JC.**

150. Structural steel reinforced columns. Conc may be subjected to 1/4 ult stress, provided (1) cross sec area of steel is not less than 1 □″; (2) spacing of lacing or battens not more than least width of col, **Ch.**

Beams and floors.

151. The common theory of beams is applicable. **Un, Ch, Mh, Ph.**

152. The steel is assumed to take all the direct tensile stresses, **L, Un, Ch, Ms, Mh, Ph.** Tensile stress in conc to be considered in calculating deflections, **JC.**

153. The stress-stretch curve of conc in comp is assumed to be a straight line, **Ch, Ph.** $n, = E_s/E_c, = 15$; for deflections, $n = 8$ to 12, **JC.**

154. At 2000 lbs/□″ extreme fiber stress, this curve may be taken as (a) a straight line; (b) a parabola, with axis vert, and vertex on neutral axis of beam; or (c) an empirical curve, enclosing an area 1/4 greater than if curve were a straight line, and with cen of grav at same height as that of area in (b), **Un.**

155. Stresses. A load, = 4 × the total working load, stresses the steel to its elas lim, and the conc to 2000 lbs/□″, **Un.** Design "based on the assumption of a load 4 times as great as the total load, **Ph.** (Total load = ordinary dead load plus ordinary live load, **Un, Ph.**)

156. The adhesion, betw conc and steel, is assumed to be sufficient to make them act unitedly, **Un, Ch, Mh, Ph.**

157. Exposed metal not considered in figuring strgth, **Un, Ch, Ph.**

158. Span = dist c to c of bed plates or other bearings, **Ms, JC.** If beam is fastened to side of a col, span is measured to cen of col, **Ms.** Span ≯ (clear span + depth of beam or slab), **JC.**

For abbreviations, symbols and references, see p 1251.

159. Shrinkage and thermal stresses to be provided for by introduction of steel, **Ch, Ph.** "Initial stress in the reinfmt, due to contraction or expansion in the conc, may be neglected," **JC.**

160. When the **shear** developed exceeds the allowed limit for conc, steel must be introduced to take the excess, **Un, Mh, Ph, JC.**

161. Allowable values for shearing stresses:

	lbs/□"
(a) With horizontal bars only	40;
(b) With part of the hor reinfmt in the form of bent-up bars, "arranged with due respect to the shearing stresses"	≯60;
(c) With thoro reinfmt for shear	≯120, **JC.**

Under (c), conc may be taken as carrying ⅓ of the shear; the remaining ⅔ being carried by bent rods or stirrups (preferably both) carrying their share within a hor dist = depth of beam, **JC.**

162. Longitudinal spacing of stirrups or bent rods ≯ 0.75 × depth of beam, **JC.**

163. Cement finish, added to the tops of slabs, beams and girders, **not to be included** in figuring strgth "unless laid integrally with the rough conc," and to be allowed no greater unit stress than that on the rough conc, **Ch.**

164. Web reinforcement. "Where the vertical shear, measured on the sec of a beam or girder, betw the centers of action of the hor stresses, > 0.02 × the ult direct comp stress/□", web reinfmt shall be supplied, sufficient to carry the excess. The web reinfmt shall extend from top to bottom of beam and loop or connect to the hor reinfmt. The hor reinfmt, carrying the direct stresses, shall not be considered as web reinfmt," **Ch.**

165. Steel in the compression sides of beams and girders. "When steel is used in the comp side of beams and girders, the rods shall be tied in accordance with requirements of vert reinfd cols with stirrups connecting with the tension rods of the beams or girders," **Ch.**

166. "When steel or iron is in the comp sides of beams the proportion of stress taken by the steel or iron shall be in the ratio of the mod of elas of the steel or iron to the mod of elas of the conc; provided, that the rods are well tied with stirrups connecting with the lower rods of the beams;" **Ph.**

167. Where slabs are used with girders and beams, the girders and beams are treated as T-beams, a portion of the slab acting as flange; **G.**

168. Portion, F, of width of slab, acting as flange.

t = thickness of slab; L = span of beam or girder;
b = breadth of beam or girder; S = dist c to c betw beams or girders.

F to be "determined by assuming that, in any hor-plane sec of the flange, the stresses are distributed as the ordinates of a parabola, with its vertex in the stress-stretch curve and with its axis in a longitudinal vert plane thru the cen of the rib of the T." Said portion to be reinforced with bars near the top, at right angles to the girder. **Un.**

169. F dependent upon hor shearing stress, $F \ngtr 20t$, **Ph**; $F \ngtr 10b$, **Mh.**

170. F governed by shearing resistce betw slab and rib; $F \ngtr S\left(1 - \frac{S^2}{L^2}\right)$ $\ngtr L/3$, $\ngtr \frac{3}{4}S$. To be assumed as thus acting, slab must be cast at same time with rib, **Ch.**

$F \ngtr L/3$, $\ngtr S$, **Ms**; $\ngtr L/4$, $\ngtr 8t + b$, **JC.**

171. T-beams to be reinfd against shear along plane of junction between rib and flange, **Un, Ph**; using stirrups thruout length of beam, **Ph.**

172. Ribs of girders and beams to be **monolithic** with floor slabs **Un, Ph.**

173. "Where reinfd conc girders carry reinfd conc beams, the portion of the floor slab acting as flange to the girder must be reinfd with bars near

For lists of Specifications for Concrete, see pp 1352, 1353

the top, at right angles to the girder, to enable it to transmit local load directly to the girder and not thru the beams, thus avoiding an integration of comp stresses due to simultaneous action as floor slab and girder flange **Un. Ph.**

Moment, M. See also ¶¶ 178, 179

174. W = load per sq ft, L = span, in ft In freely supported slabs L = free opening + depth, in continuous slabs, L = distance bet n centers of supports.

175. With concentrated or special loadings, calculate and provide for moments and shears for critical condition of loading, **Ch.**

For dead load, M obtained from the actual dead load covering all
" live load, over supports, M obtained from the actual live load spans at same time
" " " between supports M may obtain from live load covering 2 consecutive or 2 alternate spans at same time

When all spans are equal, let M_c = mom live load moment at middle of span. Then,

$$\text{for intermediate spans, } M_c = \frac{W L^2}{12}$$

$$\text{for end spans, } M_c = \frac{W L^2}{10}$$

Sum of live load moments over one support and at cen of span, $\nless \frac{W L^2}{6}$, **Ch.**

Continuity. See also ¶ 175.

176. Beams and girders considered as simply supported at ends, no allowance made for continuity, **Un. Mh.**

177. Beams, etc, calculated as simply supported, or as continuous, according to the facts, **Ch. Ms.**

178. Continuous **floor plates**, reinfd at top over supports, may be treated as continuous beams Under uniformly distributed loads, mom, M, taken at not less than $0.1\ W\ L$, $0.05\ W\ L$ with square floor plates, reinfd in both directions and supported on all sides, **Un. Mh. Ph.**

179. In floor slabs adjoining walls: if slab is reinfd in one direction, $M = \frac{W L}{8}$; if square and reinfd in both directions, $M = \frac{W L}{16}$, **Ph.**

180. Floor slabs designed and reinfd as continuous over the supports. If length of slab > 1.5 × its width, the entire load should be carried by transverse reinfmt. "Square slabs may well be reinfd in both directions." **JC.**

181. For beams and slabs continuous for > 2 spans, bending moms at cen and at support, for both live and dead loads, as follows:

In floor slabs and in interior spans of continuous beams, $M = w\ L^2/12$,
in end spans of continuous beams, ... $M = w\ L^2/10$
w = load per unit of span, L = span, **JC.**

182. In continuous spans, provide, at supports, for

negative mom = 0.8 positive mom at cen of a simply supported span.

Pos mom, at cen of continuous span, may be taken = neg mom at support, **Ms.**

Tests.

183. Bldg Commissioner may require tests of materials before or after incorporated into bldg, **Ms.** Contractor must be prepared to make load tests in any portion of bldg within a reasonable time after erection, and as often as may be reqd by engineer, **Ch, Ph, Mh, Un.** Tests must show that the constr will sustain loads as follows:

For abbreviations, symbols and references, see p 1251.

load = 2 × sum of proposed dead and live loads, **Ch**;
" = 2 × proposed live load, **Ph**;
" = 3 × proposed load, **Mh**.

184. Construction may be considered as part of the test load, **Ch.**

185. Each test load shall cover 2 or more panels, and remain in place not less than 24 hrs, **Ch.**

186. Deflection of slabs not more than $\frac{\text{span}}{800}$.

Deflection of girders $\frac{\text{span}}{800}$ × ratio of slab depth to girder depth, **Ch.**

187. Test, 45 days after completion.
Load 1.5 live load + 1.5 × dead load of finished area.
Deflection ≯ 0.001 × length of member, **Ci,b.**

CONCRETE SIDEWALKS.

Abstract of Specification

Adopted by

National Association of Cement Users

Philadelphia, January, 1908.

1. Cement. Portland, to meet specification of A S T M, adopted Jan, 1906. See p 940.

2. Sand. To pass No. 4 screen. May contain ≯ 5 % loam and clay, if these do not coat the sand grains.

∢ 60 % of the sand to pass No 10 sieve, or
35 % to pass No 10 20 30 40 sieve,
and remain on No 20 30 40 50 " , respectively.

≯ 20 % of the sand to pass No 50 sieve, or
70 % to pass No 10 20 sieve,
and remain on No 40 50 " , respectively.

3. Screenings, from crushed stone as below, and meeting sand requirements, may be substituted for sand.

4. Aggregate. Stone, crushed from clean, sound, hard, durable rock, screened dry thru ¾″ mesh, retained on ¼″ mesh.

5. Gravel, clean, hard, ranging from that retained on ¼″ mesh, to that passing ¾″ mesh.

6. Unscreened gravel, clean, hard. No particles larger than ¾″. Proportion of fine and coarse particles to conform to requirements below for conc.

7. Water, "reasonably clean, free from oil, sulfuric acid and strong alkalies."

Sub-base.

8. Sub-base to be **thoroly rammed. Soft spots** removed and replaced by hard material.

9. Fills > 1 ft thick, to be thoroly compacted by flooding and tamping in layers ≯ 6″ thick, "and shall have a slope of ∢ 1 : 1.5." "The top of all fills shall extend ∢ 12″ beyond the sidewalk."

10. "While compacting, the sub-base shall be **thoroly wetted** and shall be maintained in that condition until the conc is deposited."

Base.

11. Voids. Cem must overfill voids in sand by ∢ 5 %.

12. Mortar must overfill voids in agg, by ∢ 10 %. Proportions 1 : ≯ 8 sand and agg.

13. When the voids are not determined, 1 : 3 sand or screenings : 5 stone or gravel. "A sack of cem, 94 lbs, shall be considered to have a vol of 1 cu ft."

Mixing.

14. Hand. Sand evenly spread on a level water-tight platform, cem spread on sand. Mix dry to uniform color. Water sprayed and mass turned until homogeneous and of uniform consistency. Drenched agg added and all mixed until agg is thoroly coated with mortar.

15. Hand. With unscreened gravel. Cem and gravel "mixed dry, until no streaks of cem are visible." Water sprayed and mixed. Mortar must be equivalent to that specified above.

16. Water may be added while mixing, but conc must be turned ≮ once immediately afterward.

17. "Machine mixing will be acceptable when a conc equivalent in quality to that specified above is obtained."

18. Retempering prohibited.

Grade.

19. Grade of sidewalk ≮ sufficient for drainage, ≯ ¼"/ft, "except where such rise shall parallel the length of the walk."

Forms.

20. Lumber. clean, free from warp, ≮ 1¾" thick.

21. Upper edges to conform with finished grade of sidewalk.

22. Cross forms. "At each block division, cross forms shall be put in the full width of the walk and at right angles to the side forms," except as in ¶ 23.

23. Expansion joint. A metal parting strip ½" thick to replace a cross form ≮ once in 50 ft. "When the sidewalk has become sufficiently hard, this parting strip shall be removed and the joint filled with suitable material prior to opening the walk to traffic. Similar joints shall be provided where new sidewalks abut curbing or other artificial stone sidewalk."

24. "All forms shall be thoroly wetted before any material is deposited against them."

25. Dimensions of blocks.

Size, feet	6 × 6	5 × 5	4.5 × 4.5	4 × 4	3 × 3
Thickness, ins:					
In business districts,	6	5.5	5	4	...
In residence districts,	6	5	...	4	3

In residence sidewalks, edges may be 25 % thinner than center; min = 3".

26. Separating tool ≯ 6" wide, ¼" thick. Groove cut thru into sub-base; groove filled with dry sand before the top coat is spread; top coat cut thru to the sand after floating and troweling, "and a jointer run in the groove"; trowel then drawn thru groove again "so as to insure a complete separation of the block."

Depositing.

27. Conc carried to forms in watertight wheelbarrows. Conc must not slop over. Barrows must not be run over freshly laid conc.

28. Conc must be deposited within 1 hour after mixing, spread evenly, and tamped until water flushes to the top.

Protection.

29. Workmen must not walk on freshly laid conc.

30. Sand or dust, collecting on the base, to be "carefully removed before the wearing surface is applied."

Wearing surface.

31. Minimum thickness, ¾".

32. Mortar, 1 : 2 sand or screenings, mixed as for base, but wet enough not to require tamping, and so as to be readily floated with a straight-edge. "A thin coat of mortar shall be floated on to the base before spreading the wearing surf." Mortar spread on base within 30 mins after mixing, and floated within 50 mins after base conc is mixed.

33. Marking. "After being worked to an approximately true surf, the block markings shall be made directly over the joints in the base with a tool which shall cut clear through to the base and completely separate the wearing courses of adjacent blocks."

34. Surface edges rounded to a radius $\nless$ ¼".

35. "When partially set, the surf shall be **troweled smooth.**"

36. On grades > 5 %, surf to be **roughened** by a suitable tool "or by working coarse sand or screenings into the surf."

37. Only mineral colors shall be used, and these shall be **incorporated** with the entire wearing surf.

Single coat work.

38. Proportions, 1 : 2 sand . 4 gravel or crushed stone. **Blocks separated** as in two-coat work. Conc to be firmly **compacted** by tamping, and evenly **struck off and smoothed** to the top of the mold. "Then, with a suitably grooved tool, the coarser particles of the conc tamped to the necessary depth so as to finish the same as two-coat work."

Protection.

39. "When completed, the sidewalk shall be **kept moist and protected** from traffic and the elements for at least 3 days. The forms shall be removed with great care, and upon their removal **earth shall be banked** against the edges of the walk."

Grading adjacent to sidewalk.

40. On curb side, 1½" below sidewalk, slope $\nless$ ¼"/ft. On property side, "the ground should be graded back $\nless$ 2 ft and not lower than the walk."

CONCRETE BLOCKS.

1. Buffalo harbor. Blocks 6 ft long, abt 4 ft sq, 88.75 cu ft = 3.3 cu yds, made in wooden molds. ½ bbl Port, 2.5 cu ft sand, 7.5 cu ft pebbles, 7.5 cu ft broken stone, made a layer of conc, in mold, about 6" thick. Faces, 6" thick, of blocks on lake-face of breakwater, of finer material. Face placed first; backing placed before face had set. (Emile Low, A S C E, Trans, June '04, Vol LII, p 96.)

2. Zeebrugge breakwater, Belgium. Blocks 25 m (82 ft) long, 9 m (29.5 ft) wide, 8.75 m (28.7 ft) high, 2000 cu m (2616 cu yds), 4500 tons each. Outer conc shell, with cutting lower edge, three compartments, formed in iron framework and floated to place; placed between guides and block last sunk; sunk by admission of water, and filled up with conc, 1 cem. 2.5 sand : 6.1 broken porphyry, by means of skips of 10 cu m (13 cu yds). Top meter, rich in cem, placed above water at low tide. Seaward toe immediately protected by rubble rip-rap.

Superstructure of 55-ton blocks, laid above water; these surmounted by conc blocks, formed in place.

3. Molds for isolated monolithic sub-aqueous concrete blocks, from 150 to 222 cu yds, forming pier of trapezoidal cross-sec. The molds are bottomless boxes of trapezoidal cross-sec, composed of two sides and two end pieces, held together by 1¼" turnbuckle tie-rods acting on beams placed outside of the mold. The tie rods have, at each end, eyes in which wedge-bolts are inserted at time of erection. To remove the molds, the wedge-bolts are removed by turning up a nut on the rods which form an integral part of the wedge-bolts. This pulls the wedge-bolt from the eyes of the tie-rods and releases the walls of the molds, which are then picked up by the mold traveller, and re-assembled on the traveller ready for re-setting. Weight of mold, 40 tons. Time reqd for removing mold from a block and re-assembling for re-setting, from 45 to 60 mins. Buoyancy of timber overcome by cast iron ballast wts. Alternate blocks placed first. For intermediate blocks only the two side pieces of a mold are used. These are held in place and at their proper batter by six turnbuckle tie-rods, each passing thru a hollow square box of one-inch plank, acting as a strut. (South Pier at Superior Entry, Wisconsin. Report of Clarence Coleman, Asst. Engr Report Chf Engr, U S A, 1904, Part IV, page 3781.)

4. "Lewis holes should be cast in the blocks where practicable" and so "as not to bring excessive pres on the conc, particularly near the mortar facing or near the arrises of the block." Lewises and dogs may pull out of green blocks. Provide wooden blocks and rag cushions for use in turning over the blocks, otherwise the corners may be damaged.

5. Casting position. Blocks should be cast with the most important face down, their showing faces as nearly vert as practicable, and the back of the block on top, so that laitance, etc, rising to the surf, may appear there.

HOLLOW CONCRETE BUILDING BLOCKS.

Abstract of Specification

Adopted by

National Association of Cement Users,

Philadelphia, January, 1908.

1. Cement, Portland, to meet specification of A S T M, adopted Jan, 1906. See p 1232.

2. Sand, silicious, clean, gritty, to pass ¼" mesh sieve.

3. Aggregate, clean broken stone, free from dust, or clean screened gravel, passing ¾" mesh sieve, refused by ¼".

4. Unit of measurement for cem. Bbl = 380 lbs net; cu ft $\not>$ 100 lbs. Cem either measd in original package, or weighed; not measd loose in bulk.

5. Proportions. For exposed exterior or bearing walls.
(a) Machine-made. Semi-wet, 1 : $\not>$ 3 sand : $\not>$ 4 agg.
(b) Slush (or wet) conc (quaking or flowing), made in individual molds and allowed to harden in them, 1 : $\not>$ 3 sand : $\not>$ 5 agg.
If stone is omitted, proportion of sand may be increased if tests show no increase in voids or in absorption, and no loss of strength.

6. Water enough to perfect the crystallization of the cem.

7. Mixing. "Thoro and vigorous mixing is of the utmost importance."
(a) Hand. Cem and sand mixt dry. Water added slowly and workt in. Moistened agg spread upon mortar, or mortar upon agg. Mix.
(b) Machine preferred. Cem and sand, or cem, sand and agg, mixt dry. Water added and workt in. With wet conc, "this procedure may be varied with the consent of the bureau, etc."

8. Molding. Top surf of tampt blocks, after striking off, to be "troweled or otherwise finisht to secure density and a sharp and true arris."

9. Curing. After molding, blocks to be "carefully protected from wind currents, sunlight, dry heat or freezing for at least 5 days," and supplied with additional moisture during that time "and occasionally thereafter until ready for use."

10. Minimum age before using. 1 : 3 sand, 3 weeks; 1 : 2 sand, 2 weeks "with the special consent of the bureau, etc"; special blocks, for closures, 7 days "with the special consent of the bureau, etc."

11. Marking. All blocks to be markt with maker's name or brand, day, month and year of mfr, and proportions, as "1 : 2 : 3," etc.

12. Mortar. "All walls, where blocks are used, shall be laid up with Portland cem mortar."

13. Maximum load, including wt of wall, 8 tons per sq ft of area of blocks.

14. Thicknesses of walls. Bearing walls "may be 10 % less than is reqd by law for brick walls." In curtain or partition walls same as for hollow tile, terra cotta or plaster blocks.

15. Offsets. "Wherever walls are decreased in thickness, the top course of the thicker wall shall afford a full solid bearing for the webs or walls of the course of blocks above."

16. Under girders or joists, blocks to be made solid for $\not<$ 8" *from inside face.* If concentrated load, W, on block, > 2 tons, this applies to the blocks supporting the girder, etc; if $W > 5$ tons, it applies to blocks for $\not<$ 3 courses below, and to a dist of $\not<$ 18" each side of girder, etc.

17. In party walls, blocks must be filled solid.

18. Bond. "Where the walls are made entirely of conc blocks, but where said blocks have not the same width as the wall, every 5th course shall extend thru the wall, forming a secure bond, when not otherwise sufficiently bonded."

19. Block facing, on brick backing, "must be strongly bonded to the brick, either with headers projecting 4″ into the brick work, every 4th course being a header course, or with approved ties, no brick backing to be less than 8″."

20. Thickness of web of block (in bearing walls) $\nless$ 0.25 × ht of block.

21. Hollow space. In bearing walls, min percentage of hollow space:

Buildings of	1st	2d	3d	4th	5th	6th story
1 & 2 stories..............	33	33				
3 & 4 "	25	33	33	33		
5 & 6 "	20	25	25	33	33	33

22. Sills and lintels to be "reinforced by iron or steel rods in a manner satisfactory to the bureau, etc." When span > 54″, lintel "shall rest on block solid for $\nless$ 8″ from face next the opening and for $\nless$ 3 courses below bottom of lintel."

23. Prior to use, **application must be filed** with bureau or with chief of proper department, giving "a description of the material and a brief outline of its manufacture and proportions used," with "name of the firm or corporation, and the responsible officers thereof," "and changes in same thereafter promptly reported."

24. Certificate of approval to remain in force $\ngtr$ 4 mos, "unless there be filed with the bureau of building inspection, at least once every 4 mos following, a certificate from some reliable physical testing laboratory showing that the av" of $\nless$ 3 comp tests and $\nless$ 3 transverse tests comply with requirements; "the said samples to be selected by a building inspector or by the laboratory from blocks actually going into construction work."

25. Preliminary test. Maker to submit product to tests required, and file certificate, from a reliable testing laboratory, giving in detail the results of the tests made. Results of all tests, satisfactory or otherwise, to be filed in the bureau, open to inspection, but not necessarily for publication.

26. Additional tests. Maker or user or both "shall, at any and all times, have made such tests of the cems used in making such blocks, or such further tests of the completed blocks, or of each of these, at their own expense and under the supervision of the bureau of building inspection, as the chief of said bureau may require."

Failure to stand these tests involves immediate revocation of the certificate issued to maker.

27. Test requirements. Blocks must be subjected to transverse, compression and absorption tests, "and may be subjected to the freezing and fire tests." Freezing and fire tests not at cost of mfr.

28. Approval tests made at expense of applicant.

29. Not less than 12 samples to be selected by bureau, etc.

30. "Samples must represent the **ordinary commercial product,** of the regular size and shape used in construction. The samples may be tested as soon as desired by applicant" but $\ngtr$ 60 days after mfr.

31. Blocks, failing to stand tests, to be marked "condemned" by mfr or user, and destroyed.

32. "Tests shall be made in **series** of at least 3, except that in the fire tests a series of 2 (4 samples) are sufficient."

33. "Half samples may be used for the crushing, freezing and fire tests. The remaining samples are kept in reserve, in case duplicate or confirmatory tests be reqd "

4. "Lewis holes should be cast in the blocks where practicable" and so "as not to bring excessive pres on the conc, particularly near the mortar facing or near the arrises of the block." Lewises and dogs may pull out of green blocks. Provide wooden blocks and rag cushions for use in turning over the blocks, otherwise the corners may be damaged.

5. Casting position. Blocks should be cast with the most important face down, their showing faces as nearly vert as practicable, and the back of the block on top, so that laitance, etc, rising to the surf, may appear there.

HOLLOW CONCRETE BUILDING BLOCKS.

Abstract of Specification

Adopted by

National Association of Cement Users,

Philadelphia, January, 1908.

1. Cement, Portland, to meet specification of A S T M, adopted Jan, 1906. See p 1232.

2. Sand, silicious, clean, gritty, to pass ¼″ mesh sieve.

3. Aggregate, clean broken stone, free from dust, or clean screened gravel, passing ¾″ mesh sieve, refused by ¼″.

4. Unit of measurement for cem. Bbl = 380 lbs net; cu ft $\not>$ 100 lbs. Cem either measd in original package, or weighed; not measd loose in bulk.

5. Proportions. For exposed exterior or bearing walls.
(a) Machine-made. Semi-wet, 1 : $\not>$ 3 sand : $\not>$ 4 agg.
(b) Slush (or wet) conc (quaking or flowing), made in individual molds and allowed to harden in them, 1 : $\not>$ 3 sand : $\not>$ 5 agg.
If stone is omitted, proportion of sand may be increased if tests show no increase in voids or in absorption, and no loss of strength.

6. Water enough to perfect the crystallization of the cem.

7. Mixing. "Thoro and vigorous mixing is of the utmost importance."
(a) Hand. Cem and sand mixt dry. Water added slowly and workt in. Moistened agg spread upon mortar, or mortar upon agg. Mix.
(b) Machine preferred. Cem and sand, or cem, sand and agg, mixt dry. Water added and workt in. With wet conc, "this procedure may be varied with the consent of the bureau, etc."

8. Molding. Top surf of tampt blocks, after striking off, to be "troweled or otherwise finisht to secure density and a sharp and true arris."

9. Curing. After molding, blocks to be "carefully protected from wind currents, sunlight, dry heat or freezing for at least 5 days," and supplied with additional moisture during that time "and occasionally thereafter until ready for use."

10. Minimum age before using. 1 : 3 sand, 3 weeks; 1 : 2 sand, 2 weeks "with the special consent of the bureau, etc"; special blocks, for closures, 7 days "with the special consent of the bureau, etc."

11. Marking. All blocks to be markt with maker's name or brand, day, month and year of mfr, and proportions, as "1 : 2 : 3," etc.

12. Mortar. "All walls, where blocks are used, shall be laid up with Portland cem mortar."

13. Maximum load, including wt of wall, 8 tons per sq ft of area of blocks.

14. Thicknesses of walls. Bearing walls "may be 10 % less than is reqd by law for brick walls." In curtain or partition walls same as for hollow tile, terra cotta or plaster blocks.

15. Offsets. "Wherever walls are decreased in thickness, the top course of the thicker wall shall afford a full solid bearing for the webs or walls of the course of blocks above."

16. Under girders or joists, blocks to be made solid for $\not<$ 8″ *from inside face.* If concentrated load, W, on block, > 2 tons, this applies to the blocks supporting the girder, etc; if $W > 5$ tons, it applies to blocks for $\not<$ 3 courses below, and to a dist of $\not<$ 18″ each side of girder, etc.

COST.

1. The following data respecting prices and costs are compiled from records of actual construction as carried out by men presumably skilled in the art, and employing labor at about the usual rates. They afford only approx estimates of what may ordinarily be expected The cost of materials, transportation, and especially of labor, varies from time to time and from place to place.

2. Not only does the rate per hour for labor vary; but the amt of work turned out in a given time varies much more widely. A well matcht gang, presided over by an efficient foreman, will produce usually from two to four times the output of an indifferent gang. Even a well-meaning worker will frequently let his efficiency drop to 75 % of what may reasonably be expected; indifferent workers will produce only 30 or 20 %. The methods of payment, the character of superintendence, and the way in which the work is arranged and handled, are all very important; and a bungler, or one unfamiliar with conc operations, would probably find difficulty in keeping the total costs within double those given.

3. The **principal items**, making up the cost of conc (plain and reinfd) may be classified as follows:

Materials; Cem, sand, gravel, stone, reinfmt
Transportation to storage; Hauling, freight
Storage.
Screening, washing.
Mixing; Loading and transporting to mixer, mixing machine and power, labor and depreciation connected with it, auxiliary apparatus as mixing board, barrows, shovels, etc., and transporting conc to forms.
Forms; Erection, shifting, depreciation, material, labor.
Depositing; Dumping, spreading and ramming.
Finishing; plastering, brushing, etc.
Inspection and superintendence.
Plant (besides mixer and forms); Interest, depreciation, repairs, insurance.

Cost of Materials.

4. For *prices* of cem, sand, etc, see "Price List," under **1**, and its subdivisions, pp 1401, etc.

5. The cost of any one material, *per cu yd of conc*, varies greatly in diff cases, due to wide variations in the percentages employed for diff grades of conc, and can therefore be approximated only betw wide limits.

6. Roughly stated, the **total** cost, for **materials** alone, may be expected to fall somewhere between \$2.50 and \$7.50/cu yd of conc. The av would probably be \$4 or a little more, exclusive of reinfmt.

7. Cement. For prices, see "Price List," **1.34**, p 1403. Per cu yd of conc, betw \$1.50 and \$4, \$2 and \$3 being the more usual limits; affected chiefly by grade of cem and richness of mixture.

8. Sand. For prices, see "Price List," under **1.32**, p 1402. Per cu yd of conc, betw 15 cts and \$1, usually below 25; affected chiefly by grade, dist from bank, natural monopoly, and proportion used in mixture.

9. Gravel. In the pit, exclusive of screening, loading and hauling, from 20 cts to 75 cts per team load; affected chiefly by quality, and natural monopoly.

10. Stone. For prices, see "Price List," under **1.32**, p 1402. Av price for stone, broken to reqd size, at quarry, exclusive of cartage, about \$1 or \$1.50 / cu yd stone. Per cu yd conc, betw 50 cts and \$1. Affected chiefly by quality, dist from quarry, natural monopoly, and proportion of mixture.

11. Reinforcement. Cost will vary with the design and type employed. For iron and steel bars, see "Price List," **1.43**, p 1404.

Plain rods, 50 ton lots, at mill, cts per lb, approx:

∢ ¾", 1½; ∢ ½", 1¾; ∢ ⅜", 2; ∢ ¼", 2¼.

Ransome twisted rods, about ⅙ ct per lb more.

Other deformed bars, ¼ to ½ ct per lb more.

12. The percentage of reinfmt usually varies from about ½ % to 1½ % of the cross-sec of a beam or slab.

Cost of Transportation to Storage.

13. Freight. Cem, by rail. Freight rates vary greatly in diff localities, often due to no other apparent reason than arbitrary discrimination, running as low as ½ ct / ton-mile, and above 2 cts; in general, 1 to 2 cts.

14. By Canal. Boat loads of 100 tons of 2000 lbs each, cem, 1 to 2 cts/ ton-mile, according to dist; stone and sand, ¾ to 1½.

15. Coastwise freight. In carload lots, 0.4 to 0.6 ct / ton-mile, approx.

Cost of Storage, etc.

16. Storage. Ordinary cem barrels may be stored about 5 layers high, which requires about 1½ □ ft floor space per bbl.

17. Screening. Cost, by hand, betw 10 and 25 cts or more / cu yd of material handled. Machine screening, betw 4 and 8 cts / cu yd. To obtain the cost per cu yd of the screened material, multiply cost per cu yd by the ratio of total quantity handled to quantity accepted.

18. Washing. Cost of washing sand, gravel and crusht stone may be 5 cts or more / cu yd of material handled, for mechanical washers, handling large quantities. For small quantities, washt under unfavorable conditions, as high as 40 cts.

Cost of Mixing and Placing.

19. Mixing and placing. Total cost, exclusive of forms, from $1 to $2.50 / cu yd of conc.

20. Labor required, for fairly large quantities, on an av, one man for each 2 or 3 cu yds mixt and placed per day. On small jobs, each man will turn out much less.

21. Dry conc costs about $1 more per cu yd to mix and place than wet conc. Herman Conrow, Jr, A S C E, Trans, Vol 42, 1899, p 124.

22. Loading. From 12 to 24 cu yds of sand loaded into carts per man per day. 12 appears to be usual, but 24 not unreasonable.

23. Transportation. Av load broken stone, gravel or sand.

Wooden wheelbarrows.......2¼ to 2½ cu ft = 0.09 cu yd.
Iron wheelbarrows ... . 1.9 cu ft = 0.07 cu yd.

Cost of transportation per cu yd conc ordinarily betw 11 and 25 cts, depending largely upon the length of haul and the industry of the laborers.

Cost of Mixing.

24. Mixing (only). Much depends upon the diligence of the laborers, and the size of the mixer. Several examples indicate costs less than 10 cts / cu yd, counting labor only, while others indicate, quite regularly, about 25 cts. Sabin says "The cost of mixing conc in large quantities is seldom less than 30 cts / cu yd if allowance is made for plant."

25. As far as practicable, the course of the material should be downward; the mixer being kept above the work if possible. If an elevator is used for the conc, its entrance should be below the mixer. In subway or sewer work, the mixer can sometimes be placed below the street level and yet above the level of the work, so that it becomes unnecessary to raise the materials again after dumping them onto the street from the wagons. Much may be lost if the supply of materials and the demand for conc are not kept nearly equal, or if the conditions are such that the men cannot keep out of each other's way.

26. Ordinarily, more than half a dozen men cannot be disposed about a mixer to operate it to advantage, measuring materials, cleaning up platforms, etc (besides those actually engaged in getting the materials to and from the mixer). Cost, for labor only, should not be much over 15 cts per cu yd of conc, even with small machines.

27. Mixers, turning out from 10 to 40 cu ft of concrete per batch (or, assuming one batch every 2 mins, 10 to 40 cu yds per hour) will cost from $500 to $1000, and will require from 5 to 10 HP. to operate. Hand power machines, with a capacity of 5 cu ft per batch, about $250.

28. Cost of **setting up** a mixer, and taking it down, including carting a few miles, and depreciation, betw $50 and $100.

Up to 100 or 200 cu yds of conc, hand mixing is usually more economical than machine mixing.

29. The first cost of a **hand mixing plant,** to be operated by 8 or 10 men, estimated as follows:

8 square-pointed shovels, size No. 3	$10
3 iron wheelbarrows	35
2 rammers	5
1 mixing platform, 15 × 15 ft	10
Total	$60

30. Performance. When material is promptly delivered, batch mixers turn out, on an av, one batch in from 2 to 3 mins. A batch in one min is extremely fast working. Sometimes 4 or 5 mins are reqd. For capacities and power reqd, see under "Mixers," ¶ 27.

31. The cost of a mixing plant for conc work is variously estimated at from 3 to 5 % or more of the cost of the work.

32. The life of a mixer, under av conditions, is from 30,000 to 40,000 batches. Thus, a mixer, turning out 120 batches per day, will require renewal in about a year. A new drum will generally be needed after turning out two-thirds the total quantity.

33. Mixer to forms. Time to fill a barrow from a mixer, about 10 secs; to discharge the entire mixer at one operation, 15 to 20 secs.

34. Av barrow load of mixt conc, 1½ to 1¾ cu ft = 0.06 cu yd. One-horse carts hold about ½ cu yd; two-horse, 1 to 2 cu yds. To compute costs of hauling, etc., see Art 4 under "Cost of Earthwork," p **1025.**

35. About 10 or 15 cu yds of conc per man per 10 hour day can be loaded by shoveling.

Cost of Forms.

36. Cost, including material and labor, varies chiefly with the character of the structure; simple forms for mass work being relatively cheap, while those for detailing walls and floors of bldgs, especially in reinfd conc, are about the most expensive.

37. Material for forms betw 10 and 80 cts / cu yd of conc in place.

38. Fabrication and erection will cost from $4 to $10 **per 1000 ft B.M.** for the simpler forms of construction, in buildings, from $10 to $20.

39. The cost of forms may be as low as 10 and as high as 50 **per cent** of the total cost of the conc in place; 25 to 35 % for forms for ordinary reinfd work, 50 % or over for detailed building work.

40. The cost, **per sq ft of surface** (as one side of a wall) can be best computed for the work in hand, given the cost of the lumber and labor available; but will usually be betw 4 cts and 20 cts.

41. The cost of forms, **per cu yd of concrete,** in building constr, is stated betw $3 and $10, from $4 to $6 being sufficient for floor construction, and $5 to $7 being more usual limits for forms for reinfd work.

42. Shifting and depreciation. The figures given for cost of forms assume that the material is not used again. For special work, involving difficult and unusual details, the forms are practically worthless after they have been used. Ordinarily the lumber can be used 2 or 3 times before it is discarded. On large buildings, the forms for which are carefully designed, and where the detailing is similar thruout, forms may be used a half dozen times.

43. The labor of shifting forms will be not much less than the labor of first erecting them.

44. Cost of **labor, for placing** forms, betw 3 or 4 % and 20 % of the cost of conc in place.

Cost of Placing.

45. Cost of **fabricating** (bending, framing, &c) **and placing reinfmt,** from about ½ to 1½ cts / lb of reinfmt. Unit systems, 33 to 50 % more.

46. Depositing. The actual labor required, for depositing only, seldom amounts to more than an extra man to help dump carts, move shutes, etc; not more than a few cts per cu yd of conc placed. Records indicate from 7 cts up, but these probably include transportation from mixer to forms.

47. Spreading and ramming. Cost varies greatly with the character of the work; being as low as 15 cts / cu yd in fairly rough mass work (5 cts if the mixture is very wet); and as high as $1 or more where much care is taken in placing, tamping, ramming and spading. Less if conc is dumpt from carts or buckets in large quantities.

48. For ramming alone, from 5 to 15 or 20 cts / cu yd; seldom over 40 cts.

Miscellaneous Costs.

49. Inspection and superintendence, as usually done, about 1 to 3 % of the cost of the work. In view of the gross inefficiencies that are likely to result if the work is not well arranged or the men not kept up to standard, it may pay to expend as much as 5 or 10 %, or more.

50. Finishing. Data very variable, due probably to diff in method.

51. Washing with brush, ⅓ ct to 7 cts / sq ft of surf; with dilute hydrochloric acid, to remove efflorescence, about 20 cts / sq ft.

52. Bush hammering; 3 to 26 cts / sq ft. Pneumatic, less than 1 ct. Pointing up and brush coating, 25 cts / sq ft or more.

Total Costs.

53. Plain. For total costs, see "Mass," etc, ¶ 56.

54. Dry conc, about $1 more per cu yd than wet, due to additional labor of ramming.

55. Gravel conc $1 to $2 / cu yd cheaper than stone conc, given the same ratio of (sand + stone) to cem, the greater diff obtaining in mixtures low in cem.

56. Mass. Breakwaters, fortifications, etc, cost betw $5 and $7 / cu yd of conc in place, the av being very close to $6. Extremes as low as $1 and as high as $8.

57. Reinforced. Where work is well organized, reinfd buildings may be built for as low as $10 / cu yd of conc in place; but the general av is nearer $18, while some builders estimate roughly on $1 / cu foot ($27 / cu yd) altho few records run so high.

58. The cost depends chiefly upon the forms (see "Forms," ¶ 36). If these are well designed, so that they are easily shifted and can be used repeatedly, the cost is low; as compared with special jobs, where refinements in designing would not pay.

59. Retaining walls, foundation walls, abutments, locks, piers, etc, vary greatly, apparently owing to the widely varying difficulties of construction likely to be encountered. The extremes run from $4 to $16 / cu yd of conc in place. Quite often, however, the price will be betw $6 and $9. Reinfd walls from $3 to $10 more.

60. Arches of moderate span, say up to 30 ft, for culvert work, etc, from $5 to $10 / cu yd.

61. Buildings. Cost may be expected to fall betw $6 and $12 / cu yd of conc in place, with the av about $8 for plain, and $10 to $15 or $20 for reinfd construction.

62. For any given type of constr, all portions of a building (except foundations), such as the floors, walls, and columns, cost practically the same per cu yd.

63. Mr. L. C. Wason (E R, '09, Feb 27, p 233) gives, as **cost of buildings:**

	$ per cu ft of space enclosed			$ per sq ft of floor

PLASTERING.

THE plastering of the inside walls of buildings, whether done on laths, bricks, or stone, generally consists of three separate coats of mortar. The first of these is called by workmen the *rough* or *scratch coat;* and consists of about 1 measure of quicklime, to 4 of sand; (which latter need not be of the purest kind;) and ⅓ measure of bullock or horse hair; the last of which is for making the mortar more cohesive, and less liable to split off in spots. This coat is about ⅜ to ½ inch thick; is put on roughly; and should be pressed by the trowel with sufficient force to enter perfectly between and behind the laths; which for facilitating this should not be nailed nearer together than ½ an inch. In rude buildings, or in cellars, &c, this is often the only coat used. When this first coat has been left for one or more days, according to the dryness of the air, to dry slightly, it is roughly *scored*, or *scratched*, (hence its name,) with a pointed stick, or a lath, nearly through its thickness, by lines running diagonally across each other, and about 2 to 4 ins apart. This gives a better hold to the second coat, which might otherwise peel off. If the first coat has become too dry, it is well also to dampen it slightly as the second one is put on.

The second coat is put on about ¼ to ⅜ inch thick, of the same hair mortar, or *coarse stuff.* Before it becomes hard, it is roughed over by a hickory broom, or some substitute, to make the third coat adhere to it better.

The third coat, about ⅛ inch thick, contains no hair. and for giving it a still whiter and neater appearance, more lime is used, say 1 of lime, to 2 of sand; and the purest sand is used. This mortar is by plasterers called **stucco;** a name also applied to mortar when used for plastering the outsides of buildings. Or instead of stucco, the third coat may be, and usually is, of *hard finish*, or *gauge stuff;* which consists of 1 measure of ground plaster of Paris, to about 2 of quicklime, without sand. Hard finish works easier; but is not as good as stucco, for walls intended to be painted in oil. The plaster of Paris is for hastening the hardening.

Either of these third coats is smoothed or polished to a greater or less extent, according to whether it is to show, or to be papered, painted, &c. The polishing tools are merely, the trowel; the hand-float, (a kind of wooden trowel,) and the water-brush, (a short-handled brush for wetting the surface part at a time with water, in order to polish more freely.) For finer polishing, a float made of cork is used. The smooth piece of board about 10 to 12 ins square, with a handle beneath, on which the plasterer holds his mortar until he puts it on to the wall with his trowel, is called a *hawk.*

The more thoroughly each coat is gone over with the water-brush and trowel, (which process is called *hand floating,*) the firmer and stronger will it be. Frequently only two coats of plastering are put on in inferior rooms; or where great neatness of appearance is not needed. The first is of hair mortar, or coarse stuff; this is scratched with the broom, and then covered by the finishing coat of finer mortar, (stucco.) If this last is nearly all lime, or with but very little sand, to make it work easier, it is called a *slipped coat.* Without any sand it is called *fine stuff.* Neither is as good as stucco, if the wall is to be papered. When this is the case, the third coat also may have a little hair, to give it more strength; but this is not absolutely necessary.

A very good effect may be produced in station houses, churches, &c, by only two coats of plaster in which fine clean screened gravel is used instead of sand. When lined into regular courses, it resembles a buff-colored sandstone, very agreeable to the eye.

In purchasing plastering hair, care must be taken that it has not been taken from salted hides, inasmuch as the salt will make the walls damp. For the same cause sea-shore sand should not be used. It is almost impossible to wash it entirely free from salt.

In brick walls intended to be plastered, the mortar joints should be left very rough, to let the plaster adhere. If it is put on smooth walls, without first raking out the mortar to the depth of nearly an inch, it is very apt to fall off; especially from outside walls; as can be seen daily in any of our cities. As this raking out of brick joints is tedious and expensive, it would generally be better to use paint rather than plaster. The walls should also be washed clean from all dust; and should be slightly dampened as the plaster is put on.

To imitate granite on outer walls: after the second or smooth coat of plaster is dry, it receives a coat of lime wash, slightly tinted by a little umber, or ochre, &c. After this is dry, in case it appears too dark, or too light, another may be applied with more or less of the coloring matter in it. Finally, a wash of lime and mineral-black is *sprinkled* on from a flat brush, to imitate the black specks of granite. By this simple means, a skillful workman can produce excellent imitations. The horizontal and vertical joints of the imitation masonry, may be ruled in by a small brush, using the same black wash, and a long straight-edge.

The rough surfaces of all walls are more or less warped, or out of line; and it is not possible for the plasterer to rectify this perfectly by eye, as may be seen in almost every house. Even in what are called first-class ones, a quick eye can generally detect unsightly undulations of the plastered surfaces.

To prevent this, the process of **screeding** is resorted to. Screeds are a kind of gauge or guide formed by applying to the first rough coat, when partly dried, horizontal strips of the plastering mortar, about 8 ins wide, and from 2 to 4 ft apart all around the room. These are made to project from the first coat, out to the intended face of the second one; and while soft are carefully made perfectly straight, and out of wind with each other, by means of the plumb-line, straight-edge, &c. When they become dry, the second coat is put on, filling up the broad horizontal spaces between them; and is readily brought to a perfectly flat surface, corresponding with that of the screeds, by means of long straight-edges extending over two or more of the latter.

A day's work at plastering.

A plasterer, aided by one or two laborers to mix his mortar, and to keep his hawk supplied, can average from 100 to 200 square yards a day, of first coat; about ⅔ as much of second; and half as

47. Spreading and ramming. Cost varies greatly with the character of the work; being as low as 15 cts / cu yd in fairly rough mass work (5 cts if the mixture is very wet); and as high as $1 or more where much care is taken in placing, tamping, ramming and spading. Less if conc is dumpt from carts or buckets in large quantities.

48. For ramming alone, from 5 to 15 or 20 cts / cu yd; seldom over 40 cts.

Miscellaneous Costs.

49. Inspection and superintendence, as usually done, about 1 to 3 % of the cost of the work. In view of the gross inefficiencies that are likely to result if the work is not well arranged or the men not kept up to standard, it may pay to expend as much as 5 or 10 % or more.

50. Finishing. Data very variable, due probably to diff in method.

51. Washing with brush, ⅓ ct to 7 cts / sq ft of surf; with dilute hydrochloric acid, to remove efflorescence, about 20 cts / sq ft.

52. Bush hammering; 3 to 26 cts / sq ft. Pneumatic, less than 1 ct. Pointing up and brush coating, 25 cts / sq ft or more.

Total Costs.

53. Plain. For total costs, see "Mass," etc, ¶ 56.

54. Dry conc, about $1 more per cu yd than wet, due to additional labor of ramming.

55. Gravel conc $1 to $2 / cu yd cheaper than stone conc, given the same ratio of (sand + stone) to cem, the greater diff obtaining in mixtures low in cem.

56. Mass. Breakwaters, fortifications, etc, cost betw $5 and $7 / cu yd of conc in place, the av being very close to $6. Extremes as low as $1 and as high as $8.

57. Reinforced. Where work is well organized, reinfd buildings may be built for as low as $10 / cu yd of conc in place; but the general av is nearer $18, while some builders estimate roughly on $1 / cu foot ($27 / cu yd) altho few records run so high.

58. The cost depends chiefly upon the forms (see "Forms," ¶ 36). If these are well designed, so that they are easily shifted and can be used repeatedly, the cost is low; as compared with special jobs, where refinements in designing would not pay.

59. Retaining walls, foundation walls, abutments, locks, piers, etc, vary greatly, apparently owing to the widely varying difficulties of construction likely to be encountered. The extremes run from $4 to $16 / cu yd of conc in place. Quite often, however, the price will be betw $6 and $9. Reinfd walls from $3 to $10 more.

60. Arches of moderate span, say up to 30 ft, for culvert work, etc, from $5 to $10 / cu yd.

61. Buildings. Cost may be expected to fall betw $6 and $12 / cu yd of conc in place, with the av about $8 for plain, and $10 to $15 or $20 for reinfd construction.

62. For any given type of constr, all portions of a building (except foundations), such as the floors, walls, and columns, cost practically the same per cu yd.

63. Mr. L. C. Wason (E R, '09, Feb 27, p 233) gives, as **cost of buildings:**

	$ per cu ft of space enclosed			$ per sq ft of floor		
	max	av	min	max	av	min
Offices and stores	0.197	0.131	0.084	2.42	1.77	1.12
Factories	0.129	0.102	0.060	1.70	1.34	0.90

Mills, etc, 2d class	0.122	0.069	0.045	1.51	0.90	0.54

laid horizontally from rafter to rafter; or sloping, from purlin to purlin as the case may be; or to stout laths *t t t* about 2 to 3 ins wide, and from 1 to 1¼ thick, nailed to the rafters at distances apart to suit the gauges of the slates. Two nails are used to each slate; one near each upper corner. They may be either of copper, (which is the most durable, but most expensive,) of zinc, or of either galvanized or tinned iron. The last two are generally used; or in inferior work, merely plain iron ones, previously boiled in linseed oil, as a partial preservative from rust. Rust, however, sometimes weakens them so much that they break; and the slates are blown off in high winds, to the danger of passers by. Since good slate endures for a long series of years, it is true economy to use nails that are equally durable. In iron roofs, the slates, instead of being nailed to boards, are sometimes tied directly to the iron purlins, by wire **A square** of slating, shingling, &c, is 100 sq ft.

In laboratories, chemical factories, &c, subject to **acid fumes**, it is difficult to provide a metal fastening that will not be eaten away In such cases it is best to depend chiefly upon a layer of mortar between the slates. This will harden before the metal fastenings give way; and will hold the slates in place, while new fastenings are being inserted.

The **least pitch** considered advisable for a roof, to prevent rain or snow from being driven through the interstices between the slates, is about 26½°; or 1 vert to 2 hor; which corresponds to a rise of ¼ the span in a common double pitched roof But even at steeper pitches, rain, and more particularly snow, will be forced through the roof by violent winds; especially if laths alone be used, or even boarding alone. To avoid this, a layer of mortar about ¼ inch thick, may be spread over the touching surfaces of the slates if on laths. If on boards, the same process may be adopted; or the more common one of first covering the boards with a layer of what is called *slating felt*, but which in reality is merely thick brown paper, soaked in tar. This is sold in long continuous rolls, 28 ins wide, and weighing from 40 to 50 lbs. A 50 lb roll will cover about 300 sq ft of roof. With proper precautions against the admission of rain and snow, a pitch as flat as 1 in 2½, or even 1 in 3 may be adopted.

The thickness of slate on a roof is double; except at the *laps i s, i s*, &c, where it is triple. The lap is measured from the nail hole (under *i*) of the lower slate, to the lower edge or *tail*, *s*, of the upper one, and is usually about 3 ins In order that the showing lower edges of the slates shall, when laid, form regular straight lines along the roof, the nail holes are made at equal distances from said *lower* edges, so that any irregularity of length is concealed from view at the hidden *heads* of the slates. The slater estimates the length of his slate from the nail hole to the tail; discarding the narrow strip between the nail hole and the head If from this reduced length the lap be deducted, then one-half of the remainder will be the *gauge*, *weathering*, or *margin*, of the slating, or, in other words, the *showing* or *exposed* width of the courses of slates. The gauge in ins multiplied by the width of a slate in ins, gives the area in sq ins of finished roof covered by a single slate; and if 144 (the sq ins in a sq foot) be divided by this area, the quotient will be the number of slates required per sq ft of roof. The upper side of a slate is called its *back*, the lower one, its *bed*.

Slating, like shingling, must evidently be commenced at the eaves, and extended upward Since the beds of the slates are not exactly parallel to the boarding, and consequently do not rest flat upon it, those at the lower edge *w* would easily be broken. To prevent this, a *tilting strip* (a stout wide lath, with its upper side planed a little bevelling, to suit the slope of the slates) is first nailed around near the eaves, for the tails of the lowest course of slates to rest on. This is shown on a larger scale at T.

Slate of the best quality has a glistening semi-metallic appearance, somewhat like that of a surface of paper rubbed with black-lead pencil. That of a dull earthy aspect, is softer, more absorbent, and consequently more liable to yield to atmospheric influences, rain, frost, &c. Iron pyrites frequently occurs in slate, and since it always decomposes and leaves holes, should never be admitted on a roof. Of two qualities of slate, that which absorbs the least weight of water, when pieces of equal size are soaked for an hour or two, is generally the best; being least liable to split by frost, and become weather-worn. This test is easily applied.

In England the **different sizes** are distinguished by absurd names of no meaning. In the United States they are called 6 by 12's; 16 by 24's, &c, according to their measures in inches. They may be cut to order, of almost any prescribed dimensions, or shape. Those in common use vary from about 7 by 14, to 12 by 18. The first forms about 5 to 6 inch courses; and the last about 7 to 8 inch; depending upon how far from the head the nail holes are pierced. The farther this is, the firmer will the slating be.

Slate roofs, like iron ones, heat the rooms immediately below them very much. This is somewhat diminished when the slates are on boards, instead of laths; and still more by a coat of plaster beneath They are also liable to break when walked on; less so when bedded in mortar.

Weight of slate roofs. Slate weighs about 175 lbs. per cub foot; therefore, a sq ft, ⅛ inch thick, weighs about 1.8 lbs, $\frac{3}{16}$, 2.7 lbs; and ¼ thick, 3.6 lbs. But owing to the overlapping, a square foot of roof requires about 2¼ sq ft of slate of ordinary sizes; and if the slate is laid on boards an inch thick, the weight per sq ft of roof will be increased about 2¼ lbs; or with 1¼ inch boards, 2.8 lbs. Laths will weigh about ¼ lb per sq ft of roof.

Hence,

			Approx Weight of one sq ft of Slating, in lbs.
Slate	⅛ inch thick	on laths	4.75
"	"	on 1 inch boards	6.75
"	"	on 1¼ " "	7.30
"	3-16 "	on laths	7.00
"	" "	on 1 inch boards	9.00
"	" "	on 1¼ " "	9.55
"	¼ "	on laths	9.25
"	" "	on 1 inch boards	11.25
"	" "	on 1¼ " "	11.80

If slating felt is used, add ⅓ lb; or if the slates are bedded in ¼ inch of mortar, add 3 lbs

For the total weight borne by the *roof trusses*, that of the purlins also must be added. This will not vary much from the limits of 1½ to 3 lbs per sq ft in roofs of moderate span. Add for wind and snow, say 20 lbs per sq ft; and finally add the weight of the truss itself.

For stopping the joints between slates (or shingles, &c) and chimneys, dormer windows, &c, a mixture of stiff white lead paint, as sold by the keg, with sand enough to prevent it from running, is very good; especially if protected by a covering of strips of lead, or copper tin, &c, nailed to the mortar-joints of the chimneys, after being bent so as to enter said joints; which should be scraped out for an inch in depth, and afterward refilled. Mortar protected in the same way, or even unprotected, is often used for the purpose; but is not equal to the paint and sand. Mortar a few days old, (to allow refractory particles of lime to slack,) mixed with blacksmith's cinders, and molasses, is much used for this purpose, and becomes very hard, and effective.

SHINGLES.

White cedar shingles are the best in use; and when of good quality will last 40 or 50 years in our Northern States. They are usually 27 ins long; by from 6 to 7 ins wide; about ¼ inch thick at upper end; and about ⅝ at lower end or butt; and are laid in courses about 8⅛ ins wide; so that not quite ⅓ of a shingle is exposed to the weather.

They are usually laid in three thicknesses; except for an inch or two at the upper ends, where there are four. They are nailed to sawed shingling-laths of oak or yellow pine; about 16 ft long; 2½ ins wide, and 1 inch thick; placed in horizontal rows about 8⅛ ins apart. These are nailed to the rafters, or purlins; which, for laths of the foregoing size, should not be more than 2 ft apart from center to center. Two nails are used to each shingle, near its upper end. They should not be of less size than 400 to a lb. Wrought nails being the strongest, are the best; cut ones are apt to break by the warping of the shingles. Two pounds of such nails will suffice for 100 sq ft of roof, including waste. An average shingle 7½ ins wide, in 8⅛ inch courses, exposes 63¾ sq ins; making 2¼ shingles to a sq ft of roof, but to allow for waste, and narrow shingles, it is better in practice to allow about 3 shingles to a sq ft.

Shingling like slating, must plainly be begun at the eaves; and extended upward. For closing the joints between the shingles, and chimneys, dormer windows, &c, see at end of Slating.

Cypress and white pine are also much used for shingles, being much cheaper, but scarcely half as durable. All shingles wear quite thin in time by rain and exposure In warm damp climates they all decay within 6 to 12 years

PAINTING.

The principal material used in house-painting, is either white lead, or oxide of zinc, ground in raw (unboiled) linseed oil, by a mill, to the consistency of a thick paste. In this condition, it is sold by the manufacturers in kegs of 25, 50, and 100 lbs. To prepare it for actual use, merely requires the addition of more linseed oil, say 3 or 4 pints to 10 lbs of the keg paint, for thinning it sufficiently to flow readily under the brush.

Good painting requires 4 or 5 coats; but usually only 4 are used in principal rooms; and 3 in inferior ones. Each coat must be allowed to dry perfectly before the next one is put on. One lb of the keg paint will, after being thinned, cover about 2 sq yds of first coat; 3 yds of second, and 4 yds of each subsequent coat; or 1 sq yd of 3 coats will require in all, 1.08 lbs; of 4 coats, 1¼ lbs; of 5 coats, 1.58 lbs. The reason why the first coats require so much more than the subsequent ones, is that the bare surface of the wood absorbs it more.

When, as is usual, *raw* or unboiled oil is used for thinning, *dryers* must be added to it; otherwise the paint might require several weeks to harden; whereas, with dryers, from 1 to 3 days, according to the weather, suffice for each coat to become hard enough to receive the next one. The dryers most commonly used, are powdered litharge, in the proportion of one heaped teaspoonful; or Japan varnish, 1 table-spoonful, to 10 lbs of the keg paint. Either sugar of lead, or sulphate of zinc, may also be used instead of litharge; and in the same proportion. Although both litharge and Japan varnish are dark-colored, yet the quantity is so small as not to appreciably affect the whiteness of the paint. If the varnish is used in excess, as is often done in the hurry to have work finished, it produces cracks all over the surface. No dryer is necessary if painters' boiled oil be used for thinning. Mere boiling will not cause oil to harden more rapidly; but that intended for painters, has litharge added to it previously to boiling, in the proportion of 1½ lbs to each 10 gallons of raw oil In some works written for the use of house painters, it is asserted that boiling renders the oil too thick for any but coarse outdoor work. But this is entirely a mistake; for if the boiling be properly done, the oil will be quite thin enough for the best inside work; and will moreover be clearer than while raw; and

will impart to the painted surface a more shining appearance. The heat should be barely sufficient to produce boiling, or about 600° Fah. The boiling should continue about 1½ hours; the oil being thoroughly stirred at short intervals, to prevent the litharge from settling at the bottom. The fire may then be allowed to subside; when the operation will be completed. A sediment will then form at the bottom; which must be left behind when the oil is poured off. Although no dryer is necessary with this oil, still a little litharge may be added when great expedition demands it. Painters rarely use this oil, on account of its trifling increase of cost.

Another substance much used with the thinning oil, (except for the first coat,) is spirits of turpentine, called "turp" by the workmen. The quantity of oil may be diminished, to the extent of the added turp. This being more fluid than oil, causes the paint to work more pleasantly under the brush. It moreover diminishes the tendency of the paint to become yellow, especially in rooms kept closed for some time. It is also much cheaper than oil. It should not be used, or but sparingly, for exposed outdoor work; inasmuch as its tendency is to impair the firmness of the paint, and although its effects are scarcely appreciable indoors, they are quite apparent when the work has to resist the weather. As the fashions change in house-painting, the surface is at times required to present a *shining* or *glossy* finish, at other times a *dead* one is in vogue. The glossy one is that which the paint will naturally have, provided that no more turp than oil be used in the thinning. The dead finish is obtained by using no oil, but turp alone, for the last coat, which in that case is called a *flatting coat*. Although turp is not properly a dryer, still, as it evaporates quickly, it facilitates the hardening of the paint.

In outdoor work it is usually advisable to use more dryer than inside, so that the paint may sooner become hard enough not to be injured by dust or rain. Otherwise less would be better.

When, instead of a white finish, one of some other color is required the coloring ingredient is mixed with the white paint to be used in the last coat only; although two coloring coats are sometimes found to be necessary before a satisfactory effect is produced. The coloring ingredients may be indigo, lampblack, terra sienna, umber, ochre, chrome yellow, venetian red, red lead, &c, &c, which are ground in oil, ready for sale, by the manufacturers of the white-lead and zinc paints. They are simply well stirred into the white paint.

All surfaces to be painted, should first be thoroughly dry, and free from dust. If on wood, all plane marks, and other slight irregularities, should first be smoothed off by sand-paper when the neatest finish is required. Also, all heads of nails must be punched to about ⅛ inch below the surface. To prevent knots from showing through the finished work, (as those in white or yellow pine would do, on account of the contained turpentine,) they must first be *killed* as it is termed. A usual and effective way of doing this, is by covering them with two coats of shellac varnish, which, when dry, should be smoothed by sand paper. Another mode, not quite so certain, is by one or two coats of white lead mixed with thin glue water, or *size*, as it is called.

After these preparations, the first, or *priming* coat, is put on; in which there should be no turp; because it would sink at once into the bare wood, leaving the white lead behind it, in a nearly dry friable condition. After this the nail holes, cracks, &c, must be filled with common glaziers' putty, made of whiting (fine clean washed chalk) and raw linseed oil, boiled oil will not answer; the putty would be friable. The putty would be apt to fall out, if put in before priming, because the wood would absorb the oil, and the putty would then shrink. After the first coat is perfectly dry, the second one is put on; and for it about 1 measure of turp may be mixed with 3 measures of the thinning oil. In the third, and any subsequent coats, equal measures of turp and oil, may be used for thinning, if the work is required to dry *with a gloss*, but if it is to finish *dead*, the last coat must be a *flatting* one; or one in which the thinning oil is entirely omitted, and turp alone substituted for it.

Painters generally clean their brushes by merely pressing out most of the paint with a knife; and then keep them in water until further use. If to be put away for some time, they may be thoroughly cleaned by turp; or by soap and water. To prevent a hard skin from forming on the top of their paint when not used for some days, they pour on a little oil.

The best paints for preserving iron exposed to the weather, appear to be pulverized oxides of iron such as yellow and red iron ochres; or brown hematite iron ores finely ground, and simply mixed with linseed oil and a dryer. White lead applied directly to the iron, requires incessant renewal; and indeed probably exerts a corrosive effect. It may, however, be applied over the more durable colors, when appearance requires it. Red lead is said to be very durable, when pure. An instance is recorded of pump-rods, in a well 200 ft deep near London, which, having first been thus painted, were in use for 45 years; and at the expiration of that time their weight was found to be precisely the same as when new; thus showing that rust had not affected them.

When the size of the exposed iron admits of it, its freedom from rust may be very much promoted by first heating it thoroughly, and then dipping it into, or washing it well with, hot linseed oil, which will then penetrate into the interior of the iron. For tinned iron exposed to the weather, on roofs, rain pipes, &c, Spanish brown is a very durable color. The tin is frequently found perfectly bright and protected, when this color has been used, after an exposure of 40 or 50 years. White paint washes off in a few years by rain.

Plastered walls should if possible be allowed to dry for at least a year, before being painted in oil; otherwise the paint will be liable to blister. They may, if preferred, be frescoed (water color mixed with size) to the desired tint during the interval.

The painting of unseasoned wood hastens its decay. If the surface to be painted is greasy, the grease must first be removed by water in which is dissolved some lime.

Washes for outside work. Downing, in his work on country houses, recommends the following: *For wood work:* in a tight bushel, slack half a bushel of fresh lime, by pouring over it boiling water sufficient to cover it 4 or 5 ins deep, stirring it until slacked. Add 2 lbs of sulphate of zinc (white vitriol) dissolved in water. Add water enough to bring all to the consistence of thick whitewash. Apply with a whitewash brush. This wash is white; but it may be colored by adding powdered ochre, Indian red, umber, &c. If lampblack is added to water-colors, it

should first be thoroughly dissolved in alcohol. The sulphate of zinc causes the wash to become hard in a few weeks.

For brick, masonry, or rough-cast. Slack ½ a bushel of lime as before; then fill the barrel ⅔ full of water, and add a bushel of hydraulic cement. Add 3 lbs of sulphate of zinc, previously dissolved in water. The whole should be of the thickness of paint; and may be put on with a whitewash brush. The wash is improved by stirring in a peck of white sand, just before using it. It may be colored, if desired like the preceding.

He also gives the following cheap oil-paint for outside work on wood, brick, stone, &c; and says it becomes far harder and more durable than common paint. One measure of *ground* fresh quicklime; add the same quantity of fine white sand, or fine coal ashes; and twice as much fresh wood ashes; all the foregoing to be passed through a fine sieve. Mix well together dry. Mix with as much raw linseed oil as will make the mixture as thin as paint. Apply with a painter's brush. It may be colored like the foregoing, taking care to mix the colors well with oil before adding them. It is best to put on two coats; the first thin, and the second thick.

Also, another, said to stand 15 to 20 years: 50 lbs best white lead; 10 quarts raw linseed oil; ½ lb dryer: 50 lbs finely sifted sharp clean sand; 2 lbs raw umber. Add very little, say ½ pint of turpentine. Apply with a *large* brush.

Cement for stopping joints, such as around chimneys, &c, &c. White lead ground in oil, as sold by the keg; mixed with enough pure sand to make a stiff paste that will not run. It grows hard by exposure, and resists heat, cold, and water. Pieces of stone may be strongly cemented together by it, allowing a few months for proper hardening.

Whitewash for inside work, according to Mr. Downing, "is made more fixed and permanent, by adding 2 quarts of thin *size* to a pailful of the wash, just before using. The best size for this purpose is made of shreds of glove leather; but any clean size of good quality will answer," as thin glue-water. We will add, that the common practice of mixing salt with whitewash, should not be permitted. Paper pasted on a wall which has previously been covered with salt whitewash, is very apt to become wet, and loose, and to fall off during damp weather. The whitewash should be scraped off, and the wall or partition covered with a coat or two of thin size, to protect the paper from the effect of the salt that may still adhere to the plaster.

GLASS, AND GLAZING.

WINDOW glass is sold by the box. Whatever may be the size of the panes, a box contains as nearly 50 sq ft of glass as the dimensions of the panes will admit of.

Panes of any size may be made to order by the manufacturers. The sizes given in the following table, as well as many others, are generally to be had ready made. Ordinary window glass of all the sizes in the table, is about one-sixteenth of an inch thick, and this is the thickness supposed to be intended when a greater one is not specified. *Double-thick* glass is nearly ⅛ inch; and its price is 50 per ct more than the *single* thick. It is of course much stronger than the single.

The panes are confined to the sash by glaziers' putty, made of whiting (powdered chalk) and raw linseed oil; and by small triangular pieces of thin tin, about ⅛ inch on a side, which uphold the glass while the putty is being put on; and are allowed to remain afterward, as a protection while the putty continues soft.

30	20								

The best qualities of American glass made in the vicinity of Philadelphia, Boston, Pittsburg, &c, are for most purely *useful* purposes, as good as those from foreign countries; but when the highest degree of *beauty* is required, as in the lower front windows of first-class dwellings, fancy stores, &c, polished plate-glass of England, France, or Germany, must be used, although the price for moderate sized panes is from 5 to 8 times as great as that of the best quality single-thick American. Its perfectly *smooth* surface, free from distorted reflections, also makes it the best for covering pictures; still, if carefully selected American panes be used for this purpose, few except critics in glass will detect the difference.

A thick glass is made expressly for flooring, up to 1 inch thick, and up to 50 inches by 9 feet dimensions. Also, for skylights, from ¼ to ½ inch thick. This can be furnished to order of any size up to 40 inches by 8 or 10 feet. The smaller sizes can also be had *ground*. Grinding prevents the entrance of the full glare of the sun; and, moreover, diffuses the light over a much greater width of space below.

Strength of glass. Tensile 2500 to 9000 lbs per square inch. Boston rods by author, 3500 to 5200. Crushing strength, 6000 to 10000 lbs per square inch. Transversely, (by the writer's trials) flooring glass, 1 inch square, and 1 foot between the end supports, breaks under a center load of about 170 lbs; consequently, it is considerably stronger than granite, except as regards crushing; in which the two are about equal.

REMARK. Window and other glass which contains an excess of potash or of soda is very liable to become dull in time, owing to the decomposition of those ingredients by atmospheric influences.

ROPE.

The strength of rope varies greatly. Pieces from the same coil may vary 25 per cent. The table below supposes an average quality **Manila.** Good **Italian hemp** is considerably stronger. The **tarring** of ropes is said to lessen their strength; and, when exposed to weather, their durability also. We believe that its use in standing rigging is partly to diminish contraction and expansion by alternate wet and drying weather. A few months of **exposed work** weakens ropes 20 to 50 per cent.

Table of Manilla rope.

1.75	5½	.998	9.80	21952	4.45	14	6.47	37.0	82880

Working loads. For manila ropes from 1 to 1¾ ins diam, running at different speeds over sheaves of the diams stated, Mr. C W. Hunt (Trans Am Soc Mechl Engrs, Vol. XXIII, 1901) gives a table embodying approximately the following results of experience. Working load = C × ultimate strength of new rope. D = minimum diam of sheave, in ins.

Speed	ft per min	as for work on	C	1″ rope D	1¾″ rope D
Slow	50 to 100	derrick, crane, quarry	0.140	8	14
Medium	150 to 300	wharf, cargo	0.056	12	18
Rapid	400 to 800		0.028	40	70

Such ropes wear out rapidly. A rope 1½ ins diam wears out in lifting from 7,000 to 10,000 tons of coal. On the other hand, 1½ inch transmission ropes, running 5000 ft per min and carrying 1000 H. P. over sheaves 5 ft and 17 ft in diam, last for years.

Mr. Hunt's figures for ultimate strength, based upon tests of full-sized specimens of manila rope made by three independent rope-walks and purchased in open market, are practically identical with those given in our table above, as are also those of Prof. B. Kirsch, of the Imperial Royal Technological Industrial Museum, Vienna, quoted by Mr. Hunt.

WEIGHTS AND STRENGTHS OF WIRE ROPES.

Wire Rope manufactured by **John A. Roebling's Sons Co., Trenton, N. J.,** and others. See price list The prices and weights given are for ropes with *hemp* centers When made with *wire* centers, the prices per foot are 10 per cent. higher, and the weights 10 per cent. greater. **A. Leschen & Sons Rope Co., St. Louis, Mo.** "Hercules" rope; strengths and prices average about 50 per cent. higher than for cast steel rope.†

Notes on the Use of Wire Rope, by the Roebling's Company.

The ropes with 19 wires per strand are the more pliable, and therefore best adapted for **hoisting** and **running** rope. The others are stiffer and better adapted for **guys,** &c. Ropes of iron or steel, up to 3 inches diameter, made to order. Hemp center rope is more pliable than wire center. Wire rope **must not be coiled or uncoiled** like hemp rope. When on a reel, the reel should be mounted on a spindle or flat turn-table in order to pay off the rope. When forwarded in a small coil without a reel, roll the coil on the ground like a wheel, and thus run off the rope. Avoid untwisting and short bends. **To preserve wire rope,** apply raw linseed oil (which may be mixed with an

* **For the safe working load,** take one-fifth to one-seventh of the breaking load, according to speed.

† For discounts, see price list

equal quantity of Spanish brown or lamp-black) with a piece of sheepskin, keeping the wool against the rope. **If for use in water or underground,** add 1 bushel of fresh-slacked lime and some sawdust to 1 barrel of tar. Boil the mixture well and saturate the rope with it while hot.

Galvanized wire rope for rigging is cheaper and more durable than hemp rope; and does not stretch permanently under great strains. Its bulk is one-sixth and its weight one-half that of hemp rope. Crucible cast-steel wire ropes are much more durable than iron ones. They should be kept well lubricated.

PAPER.

24 sheets 1 quire. 20 quires 1 ream.

Sizes of drawing papers.

	Ins. Ins.		Ins Ins
Antiquarian	31 × 52	Super Royal	19 × 27
Double Elephant	26 × 40	Royal	19 × 24
Atlas	26 × 34	Medium	17 × 22
Imperial	21 × 30	Demy	15 × 20
		Cap	13 × 17

The English drawing-papers are stronger and superior to the American. Those by Whatman have a high reputation; they are, however, of different qualities. When paper is pasted on muslin, the difference in quality is not so important. Of paper in rolls, the German makes are the best. There is but little of other makes imported.

Both white and tinted papers, for the use of engineers, are made in continuous rolls, without seams. Widths 36, 42, 54, 58, and 62 ins; usual lengths 40 yds; but can be had to order to 400 yds or more. These may also be had mounted on muslin, in rolls 10 to 40 yds long.

Cartridge or **pattern** paper is furnished in long rolls, of same lengths as white paper, mounted or not; widths up to 54 ins. Color, a light buff.

Tracing paper. Most of that sold, whether domestic or foreign, tears so readily as to be of comparatively little service. Parchment paper, 37 and 38 ins wide, rolls of 20 and 33 yds, is better, but does not take ink perfectly.

Tracing cloth, usually called *tracing muslin*, and sometimes *vellum cloth*, is altogether preferable to tracing paper, on account of its great strength. Widths 18, 30, 36, and 42 ins; lengths to 24 yds.

Profile paper is made in widths of 9 ins and 20 ins, and in single sheets or in long, continuous rolls.

Cross section paper, mounted or unmounted, tracing paper and cloth, are furnished in sheets and in rolls, ruled in quarters, fifths, eighths, tenths, twelfths, and sixteenths of an inch, or in millimeters.

Colors. Since the introduction of blue printing, tinted drawings are seldom made, except for architectural effect; but colors may be used to advantage on black-line prints from tracings, p 1390. A good draughtsman needs but few colors; say India ink, Prussian blue, lake, or carmine, light red, burnt umber, burnt sienna, raw sienna, gamboge, Roman ochre, sap green. Winsor & Newton's colors are among the best in use. Purchase none but the very best India ink. Cakes of colors should always be wiped dry on paper, after being rubbed in water; and but little water should be used while rubbing; more being added afterward.

Lead pencils. *Genuine* A. W. Faber's Nos. 2, 3, and 4, are very good. The hardness increases with the number. Nos. 3 and 4 are good for field-book use: which to prefer, will depend on the character of the paper; No. 3 for smooth, and No. 4 for the coarser or more granular papers. His *lettered* pencils are of a higher grade and better suited for draughting. "H" stands for "hard," "B" for "soft." The degree of hardness or of softness is indicated by the number of H's or of B's. "F" (intermediate) corresponds with No. 3. Dixon's American pencils are good. The office draughtsman should have a flat file, or a piece of fine emery paper glued to a strip of wood, upon which to rub his lead to a fine point readily, after using the knife.

BLUE-PRINTS, ETC.*

Art. 1. (a) In order to obtain the best results, all **unnecessary exposure**, either of the sensitized paper or of the solutions, to sunlight or to other white light should be avoided.

(b) **Cleanliness** is of the first importance. The vessels in which the solutions are made and mixed must be scrupulously clean, and, if washed with soap, must be carefully rinsed with clean water. They should be left full of water when not in use. The presence of free alkali of any kind is fatal to good results, and immediately destroys the blue color of a finished print. See Art. 19 (b). The solutions must not be allowed to come in contact with iron.

Art. 2. (a) **The Solution** used in sensitizing the paper for blue-prints is usually that of *ferri*cyanide of potassium (*red* prussiate of potash) † and ammoniocitrate of iron (citrate of iron and ammonia) in water.

(b) The two salts are usually **dissolved separately** and the two solutions then mixed. The potassium salt should be broken up fine. The iron salt is usually quite pure and dissolves very rapidly. It may be kept indefinitely in a solid state if perfectly dry, but it readily absorbs moisture, and then becomes sticky and unfit for use; and the solution is apt to become mouldy after a few days, either alone or when mixed with the potassium solution. Hence, it should be prepared (in a dark room) in small quantities as required.

Art. 3. (a) The following is an average of several **recipes** that give excellent results:

Solution A. 1 ounce of red prussiate of potash to 6 ounces of water, or 2½ ounces of the salt to a pint of water.

Dissolve thoroughly and filter. The solutions may be sufficiently filtered through raw cotton, and much more rapidly than through paper.

Solution B. 1½ ounces of ammoniocitrate of iron to 6 ounces of water, or 4 ounces of the salt to 1 pint of water.

Dissolve thoroughly. Filter, unless the solution is perfectly clear.

(b) Keep the two solutions in separate glass-stoppered bottles in a dark place until they are to be used. Then mix them in equal parts, and filter the mixture. Take care that no undissolved particles of the red prussiate get into the double solution. It must be rejected when its brown color changes to bluish green.

(c) The combined solution will **cost** amateurs from 1 to 2 cents per ounce to make. About 4 ounces **will suffice for** coating 100 square feet of paper.

(d) If a few drops of strong ammonia solution be added to the citrate solution, B, until the odor is quite perceptible, the addition of a saturated solution **of oxalic acid** in water to the double solution **will hasten the printing in cloudy weather.** 10 per cent of the oxalic-acid solution will increase the rapidity of printing about 2½ times; 20 per cent., 5 times; 30 per cent., 10 times; but with more than 20 per cent., it is difficult to get clear white lines. In sunlight the difference is much less marked. (*Engineering News*, Dec. 15, 1892.)

Art. 4. (a) Where fine work is not essential, any well-sized **paper**, sufficiently tough to bear the washing, will answer. For important work use paper of fine uniform texture and smooth hard surface, free from injurious chemical substances. If the solution penetrates below the surface, a portion of the chemicals may remain in the paper in spite of the washing, and damage the result. Many papers are made especially for this purpose. The Saxe (German) and Rives (French) papers are considered among the best. Johannot and Steinbach papers give good prints, but are not very strong. Weston's and Scotch linen papers are stronger, and the latter gives excellent prints. Before sensitizing a large quantity of paper of a new kind, try a small sheet of it. **Linen** for sensitizing is also sold by dealers in photographic material and engineers' supplies.

Art. 5. (a) **The solution is applied** (in the dark room of course) to one side only of the paper. This is sometimes done by "**floating**" the paper upon the solution, taking care that none gets upon the *back* of the sheet.

"Modern Reproductive Graphic Processes," by Lieut. J. S. Pettit, D. Van Nostrand Co., Science Series, No. 76, 50 cents, deals chiefly with artistic photography, lithography, etc.

See also paper by Benj. H. Thwaite, Proc's, Inst'n Civ. Eng'rs, Vol. lxxxvi, p. 312, reprinted in Engineering News, Nov. 27, 1886.

† *Not* the *ferro*cyanide or *yellow* prussiate.

The paper is held by two diagonally opposite corners, and the diagonal joining the other two corners is then allowed to touch the surface of the liquid. Then the two corners held in the hand are dropped first one and then the other. The paper should then be lifted, one half at a time, to see whether any air bubbles have been formed under it. If so, they may be removed by drawing over the solution that half of the sheet under which they occur, while the other half is held up from the liquid. One or two minutes suffice for floating, and the paper is then drawn out over an edge of the bath draining off the surplus liquid. This process requires a tray larger than the sheet, and the inner surface of the tray must be not only water proof, but also proof against chemical action from the solution. Considerable care is required in the manipulation.

Art. 6. (a) The solution is usually applied by means of a soft wide **brush** (such, for instance as those used for wetting the leaves in letter-copying books) or a large soft **sponge** entirely free from sand or other grit.

Art. 7. (a) In applying the solution, the paper may be laid upon a board covered with soft smooth **oil-cloth,** which, after each sheet is sensitized, should be wiped off, to avoid smearing the back of the next sheet.

(b) **The operation** must be quickly performed, so that no portion of a sheet may become dry before its entire surface has been coated. For very large sheets it may be necessary, for this reason, to employ two persons. First cover the sheet by strokes of the wet sponge or brush, moved in the direction of the length of the paper, and then, immediately, by light strokes at right angles to these and with the sponge or brush squeezed out, so that the solution may be uniformly and thinly distributed over the entire surface. Wash out the sponge immediately in the dark room.

Art. 8. (a) The paper is then hung up **to dry** in the dark room, by means of clips, of any convenient form and free from iron. Small sheets may be hung by one corner; larger sheets by two adjacent corners, or by three or more places (according to size) along one edge, taking care to buckle this edge slightly, so that the paper may not be stretched in drying. If the sheets are hung over a rod or rail the solution will dry unevenly at the bend. In order that the whites in the print may be clear, the air should be warm, so that the paper may dry quickly and the solution be thus prevented from penetrating it deeply.

Art. 9. (a) Make sure that the paper is **perfectly dry** before it is used or put away, and see that it is kept both *dry* and *dark* until it is wanted for use. If carefully prepared and preserved it will retain sensitiveness for a long time, but the best results are obtained with fresh paper, and it is best not to keep it more than a month or two.

Art. 10. (a) **The tracing paper** or tracing cloth should be of a bluish cast (a yellow paper delays printing), thin (see Art. 15,), and as nearly transparent as possible. It should be preserved, both before and after drawing, from long exposure to light, which tends to render it opaque.

(b) Both before and after drawing, it should be kept either flat or rolled, and not folded, because folds render it difficult to bring the drawing into perfect contact with the sensitive paper in printing.

Art. 11. (a) **The drawing** or tracing should be made with the best India ink, rubbed very black. The addition of a little gamboge or chrome yellow increases the opacity. Lines drawn in chrome yellow and in gamboge print well; but Prussian blue or carmine should be rendered more opaque by the addition of a little Chinese white or flake white. Hold the tracing up to a strong light, in order to detect any weak places in the lines.

Art. 12. (a) **Printing** consists in exposing the sensitive paper to the action of light, the drawing being placed between the light and the sensitive surface. The arc **electric light** prints more slowly than direct sunlight, but has the advantage of constancy in all weathers and at all hours, and of fixedness of position. See Art. 16 (a).

(b) Place the frame with its face perpendicular to the rays of light, as nearly as may be, and see that no shadows, as of trees, buildings, etc., are allowed to fall upon a portion of the drawing.

(c) All handling of the paper, such as cutting it to size or placing it in the frame, should be done in a weak light.

Art. 13. (a) To secure close contact between the tracing and the sensitive paper (see Art. 15,) they are usually placed in a **printing-frame.** The essential parts of an ordinary frame are: the frame proper, a plate of clear glass for the passage of the light, and a padded back, which, by means of clamps and springs, presses the two sheets closely together and against the glass.

(b) The tracing is laid in the frame, with its drawn side next to the glass (but see Art. 16 b), and then the sensitive paper, with the sensitive side next to the tracing. Finally, the padded back is placed in the frame.

(c) The back is often made in two halves, hinged together and each provided with a spring, so that one half may be raised to permit examination of the progress of the exposure, while the other half, remaining clamped, holds the tracing and the sensitive paper in position.

(d) By using a frame left open at both ends long strips of sensitive paper may be used, a part at a time, the rest being rolled up at the ends of the frame and wrapped for protection from light.

(e) In any frame it is important that the glass be sufficiently thick to withstand the pressure required in order to secure close contact between the two papers (see Art. 15, below), of excellent quality, and free from defects which would obstruct or unequally refract the light. The glass should be carefully cleaned before printing.

(f) Improved forms of printing-frames have rubber air-cushions in place of flannel pads. In others the necessary pressure is secured by means of a vacuum produced between the tracing and the glass by means of a pump.

(g) Printing-frames are supplied by dealers. The prices, including glass, vary from about $2 for frames 10 x 12 inches, to $30 or $45 for frames 36 x 60 inches. Frames running on rollers, with fittings for exposing them outside of windows, are also furnished, at prices varying with the dimensions and the requirements.

(h) For large blue-prints, Prof E C. Cleaves, of Cornell University, uses, instead of a frame, a wooden cylinder covered with felt and revolving on its axis. Upon this cylinder the tracing and sensitive paper are stretched by means of a suitable clamping device, and the cylinder is then revolved in the sunlight. This method dispenses with the use of glass. It of course requires a longer exposure than the ordinary method. (*Trans Am. Soc. Mech. Eng*, vol. viii p. 722.)

(i) For still larger prints, Prof. R H Thurston stretches the two papers upon a thin board, which is then sprung into a curve and held in that shape, keeping the papers in tension upon the convex side This method also dispenses with the use of glass, and, the curvature of the board and the papers being but slight the whole of the paper is exposed to the light at one and the same time (*Trans. Am. Soc. Mech. Eng.*, vol. ix, p. 696)

Art. 14. (a) **The time required for exposure** varies with the color, directness, and intensity of the light, with the thickness and opacity of the tracing paper, with the blackness of the drawing, with the materials and the care used in sensitizing the paper, and with the freshness of the latter, from two or three minutes to hours or even days. Roughly, we may say that in full sunlight, in Philadelphia, about three minutes ordinarily suffice from noon to 2 P. M., and ten minutes at 10 A. M. or 4 P M , in the shade, thirty to forty-five minutes at noon; but no fixed rules can be given Experience must decide in each case. A preliminary experiment may be made with a small frame. If the back of the frame is in two or more pieces, the process may be inspected from time to time.

(b) If perfectly opaque ink be properly used, the blue background may be printed very dark without spoiling the lines, but over-exposure in printing renders the background first blackish and then of a dingy shade See Art 17 (c) and (d). Drawings in pale ink must be printed very lightly, in order that the lines may remain white and it is best to use with them a weak light, or to protect them by tissue paper or ground glass. See Art. 18 (a).

Art. 15. (a) To obtain perfectly sharp impressions, the side of the tracing upon which the drawing is made should be in **immediate contact** with the sensitized surface of the blue-print paper, especially if, as with sunlight, the direction of the light is variable; for, if any appreciable distance intervenes between the two, as in printing through cardboard (see Art. 16, below), the shadows cast by the lines of the tracing will move over the sensitized surface as the direction of the light changes, and thus give a blurred impression. In most cases, however, it is practically out of the question to place the two surfaces in this way, because that position gives a reversed impression as regards right and left.* Hence a thin tracing paper or linen is recommended in Art. 10 (a). For the same reason it is imperative that the two papers be firmly and evenly pressed against the glass.

Art. 16. (a) By using a light which is constant in position relatively to the surface of the tracing, such as an arc electric light, it is possible, by prolonging the exposure for hours or even days, to obtain blue-prints **from drawings made upon stout drawing paper** or even upon **bristol board.**

(b) With sunlight the same object may be accomplished. either by placing the original with its back to the glass, and the sensitive paper (which should be very

* A print, thus reversed in position, may of course be easily read by means of a mirror. This is commonly done with Patent Office drawings.

thin) with its back to the sunlight, or by placing the printing frame in the bottom of a deep and narrow box, so that the light can shine directly upon the frame only when approximately parallel with the long sides of the box To print rapidly, the sunlight must be kept full upon the frame by frequently moving the box.

Art. 17. (**a**) The print, when sufficiently exposed, is taken from the frame, and both its face and back are **washed thoroughly** in clean water until the characteristic blue color is perfectly developed.

(**b**) The washing should be done in a tray with a flat bottom larger than the largest print to be washed, and care should be taken not to injure the surface of the prints by hard rubbing or by sharp bending, or otherwise. It is better to have a circulation of water in the tray, not only to keep the water clean, but also to bring about the necessary agitation of the prints without handling them.

(**c**) The washing may be hastened, and dark or "over-exposed" prints may be lightened somewhat, by having the water warm, say at 90° or 100° Fahrenheit.

(**d**) Over-exposed prints may also be lightened by immersing them in water rendered slightly alkaline by ammonia. In this bath they at once assume a purple tint, which soon becomes weaker. At the proper moment, which must be learned by experience, the alkaline action must be stopped by drawing the print rapidly through a solution of 1 part of hydrochloric ("muriatic") acid (H. Cl) in 100 parts of water.

(**e**) Continue washing until the water has for some time come off perfectly clear. Then hang the prints up smoothly to dry.

Art. 18. (**a**) After washing, the application of a solution of from 1 to 5 per cent. of hydrochloric acid, or of oxalic acid, in water, intensifies the blue color, and is therefore useful in bringing out pale or "under-exposed" prints; but the prints must then be afterward washed again in pure water Hydrochloric acid applied *before* washing, or to imperfectly washed prints, will make the *lines* show blue.

Art. 19. (**a**) **To erase** a (white) line on a blue-print, go over the line with the sensitizing solution applied with a clean brush or *quill* pen. This should be done in a weak light. Then expose the entire print and re-wash

(**b**) **White lines are added** to blue prints, usually in Chinese white; but the blue color may be removed, showing the white paper beneath, by applying a saturated solution of concentrated lye (caustic soda or potash) or of carbonate of soda* or carbonate of potash, with a fine clean pen nearly dry. If laid on too freely, it spreads rapidly. Even if the pen is perfectly clean, the surface thus produced has a yellowish cast as compared with the white of the paper. The carbonate solutions act more slowly than the lye, but not less surely, and they are not injurious to the skin, whereas the lye burns badly. The ordinary lime-water sold by druggists makes little or no impression upon the blue color. **If red, instead of white,** lines are desired, mix with the soda or potash solution ordinary carmine writing-ink, in such quantity (to be ascertained by trial) as will give the desired color.

Art. 20. (**a**) Blue prints which are to be subjected to much handling should be **mounted** upon cloth, or the prints may be made, in the first place, upon sensitized tracing linen.

---

*Either carbonate ("washing-soda") or bicarbonate ("baking-soda") will answer.

MODERN EXPLOSIVES.

Art. 1. Most of the explosives, which, of late years, have been taking the place of gunpowder, **consist of** a powdered substance, partly saturated with nitro-glycerine, a fluid produced by mixing glycerine with nitric and sulphuric acids.

Art. 2. Pure **nitro-glycerine,** at 60° Fah, has a sp grav of 1.6. It is odorless, nearly or quite colorless, and has a sweetish, burning taste. It is poisonous, even in very small quantities. Handling it is apt to cause headaches. It is insoluble in water. At about 306° Fah it takes fire, and, if unconfined, burns harmlessly, unless it is in such quantity that a part of it, before coming in contact with air, becomes heated to the exploding point, which is about 380° Fah.

N-G, and the powders containing it, are always **exploded by means of** sharp percussion. See Arts 36, &c. After N-G is made, great care is required to wash it completely from the **surplus acids remaining in it** from the process of manufacture. Their presence, either in the liquid N-G, or in the powders containing it, renders the N-G liable to spontaneous decomposition, which, by raising the temperature, increases the danger of explosion.

Art. 3. N-G freezes at about 45° Fah. It is then very **difficult of explosion,** and must be thawed *gradually*, as by leaving it for a sufficient length of time in a comfortably warm room, or by placing the vessel containing it in a second vessel containing hot water, not over 100° Fah; but never by exposing it to intense heat, as in placing it before a fire, or setting it on a stove or boiler. Extra strong caps are made for exploding N-G and its powders when frozen.

Art. 4. N-G, owing to its incompressibility, is **liable to explosion through accidental percussion.** This, and its **liability to leakage,** render it inconvenient to transport and handle. Hence it is rarely used in the liquid state in ordinary quarrying and other blasting. In the oil regions of Penna, it is largely used in **oil wells,** in order to increase the flow. For this purpose it is confined in cylindrical tin casings, from 1 to 5 inches diam, called torpedo-shells. These are suspended from, and lowered into the well by means of, a cord or wire wound on a reel; and are destroyed when the charge is exploded. They are about 1 inch less in diam than the well, and contain usually from one to twenty quarts = 3 lbs, 5⅛ oz to 66 lbs, 6¼ oz of N-G. They are pointed at their lower ends, in order to facilitate their passage through the oil or water which may be in the well. When a greater charge than about 66½ lbs is required, two or more of these shells are placed in the well, one on top of another, the conical point on the lower end of each one fitting into the top of the one next below. In this case, the N-G is fired by means of a cap or series of caps placed in the top of the charge before it is lowered. When the charge is in place, the caps are exploded by electricity led to them by conducting wires, as in Art 37, or (as in the method more commonly practised) by letting a weight fall on them.

When a well has been repeatedly torpedoed, and a cavity has thus been formed in it so large that the space surrounding a torpedo would interfere too greatly with the effect of the explosion of the N-G on the walls of the well, the latter is placed directly in the well, by lowering a tin cylinder, filled with it, and provided with an automatic arrangement which allows the N-G to escape when at the bottom of the well. The N-G is then fired by a torpedo suspended on a line, and having caps placed in its top. These caps are exploded by a leaden or iron weight sliding down the line, or by electricity. When the rock is seamy, the N-G is confined in short cylindrical tin shells, lowered into the cavity, and fired by a torpedo. It is also used for increasing the flow of springs of *water*. It of course cannot be used in **hor or upward** holes, such as often occur in tunneling, &c.

Art. 5. N-G explodes so suddenly that **very little tamping is required.** Moist sand or earth, or even water, is sufficient. This, with the fact that N-G is unaffected by immersion in water, and is heavier than water, render it particularly **suitable for sub-aqueous work,** or for holes containing water, provided the rock has no seams which would permit the N-G to escape. **If the rock is seamy,** the N-G must be confined in a water-tight casing. Such casings, however, necessarily leave some spaces between the rock and the explosive, and these diminish considerably the effect of the latter.

Art. 6. The great **explosive force of N-G is due** partly to the very large volume of gas into which a small quantity of it is converted by explosion, and

partly to the *suddenness* with which this conversion takes place, the gases being liberated almost instantaneously,* while with gunpowder their liberation requires a longer time. The suddenness of the explosion increases its effect, not only by applying all of its force practically at one instant, but also by greatly *heating* the gases produced, and thus still further increasing their *volume*.

Art. 7. The liquid condition of N-G is useful in causing it to **fill the drill-hole completely,** so that there are no vacant spaces in it to waste the force of the explosion. On the other hand, the liquid form is a disadvantage, because, when thus used without a containing vessel in seamy rock, portions of the N-G leak away and remain unexploded and unsuspected, and may cause accidental explosior at a future time.

Art. 8. N-G is stored in tin cans or earthenware jars. If properly washed from acid it does not injure tin. For transportation, these cans or jars are packed in boxes with sawdust, or in padded boxes, and loaded in *wagons*. The R R companies do not receive it.

Art. 9. When N-G and its compounds are *completely* exploded, **the gases given out** are not troublesome, but those resulting from *incomplete* explosion such as generally takes place, or from combustion, are very offensive.

Art. 10. For convenience, we apply the name "**dynamite**" to any explosive which contains nitro-glycerine mixed with a granular absorbent; "**true dynamite**" to those in which the absorbent of the N-G is "Kieselguhr,"† or some other *inert* powder which takes no part in the explosion; and "**false dynamite**" to those in which the absorbent itself contains explosive substances other than N-G.

Art. 11. The absorbent, by its granular and compressible condition, **acts as a cushion to the N-G,** and protects it from percussion, and from the consequent danger of accidental explosion.

N-G undergoes no change in composition by being absorbed; and it then freezes, burns, explodes, &c, under the same conditions as to pressure, temperature, &c, as when in the liquid form. The cushioning effect of the absorbent merely renders it more difficult to bring about sufficient percussive pressure to cause explosion. The absorption of the N-G in dyn enables the latter to be used in *hot* holes, or in holes drilled *upward*.

Art. 12. N-G and dyn **explode much more readily when rigidly confined,** as by a *metallic* vessel, or by the walls of a hole drilled in rock, than when confined by a *yielding* substance, as wood. Therefore the fact that dyn, not being liquid, can be packed in *wooden* boxes, renders it safer than N-G which has to be kept in stone or metal vessels.

Art. 13. True dynamites must contain at least about 50 per cent of N-G. Otherwise the latter will be too completely cushioned by the absorbent, and the powder will be too difficult to explode. False dynamites, on the contrary, may contain as small a percentage of N-G as may be desired; some containing as little as 15 per cent. The added explosive substances in the false dynamites generally contain large quantities of oxygen, which are liberated upon explosion, and aid in effecting the complete combustion of any noxious gases arising from the N-G.

Art. 14. Dynamites which contain large percentages of N-G explode (like the liquid N-G Art 6) with great suddenness, tending to *shatter* the rock in their vicinity into small fragments. They are most useful in *very hard* rock. In such rock, **No 1 dynamite**, or that containing 75 per cent of N-G, is roughly estimated to have **about 6 times the force of an equal wt of gunpowder.**

For soft or decomposed rocks, sand, and earth, the **lower grades** of dynamite, or those containing a smaller percentage of N-G, are more suitable. They explode with less suddenness, and their tendency is rather to upheave large masses of rock, &c, than to splinter small masses of it. They thus more nearly resemble gunpowder in their action.

Judgment must be exercised as to the **grade and quantity of explosive** to be used in any given case. Where it is not objectionable to break the rock into small pieces, or where it is desired to do so for convenience of removal, the higher, *shattering* grades are useful. Where it is desired to get the rock out in large masses, as in quarrying, the lower grades are preferable.

For very difficult work in hard rock, and for submarine blasting, the highest grades, containing 70 to 75 per cent of N-G, are used. A small charge of these does the same execution as a larger charge of lower grade, and of course does not require

* Such sudden liberation of gas is called "**detonation.**"

† Kieselguhr is an earthy, silicious limestone, composed of the fossil remains of small shells. Each shell acts as a minute receptacle for nitro-glycerine. Kieselguhr is found in Hanover, Germany and in New Jersey.

the drilling of so large a hole. In submarine work their sharp explosion **is not** deadened by the water.

For general railroad work, ordinary tunneling, mining of ores, &c, the **average grade**, containing 40 per cent of N-G, is used; **for quarrying**, 35 per cent; **for blasting stumps**, trees, piles, &c, 30 per cent; **for sand and earth**, 15 per cent.

Art. 15. Dynamite, like N-G, **can be readily exploded under water**, provided it is so immersed as not to be *scattered;* but **long exposure to water is injurious** to it. In the higher grades, the water, by its greater affinity for the absorbent, drives out the N-G. In the lower grades it is apt to wash away the salts used as additional explosives.

Art. 16. In dyns containing a large percentage of N-G, the latter is **liable to exude** in liquid form, or to "leak," especially in warm weather, and then to explode through accidental percussion. The same danger exists, even though the percentage of N-G be small, if the absorbent has but small absorbing power, and is, consequently, easily saturated.

Art. 17. True dyn resembles moist brown sugar. **Its properties are** generally those of the N-G contained in it. Thus, it takes fire at about 350° F, and burns freely. It freezes at 45° F, and is then difficult to explode. It is not exploded by friction, or by ordinary percussion, but requires, for general purposes, a strong cap, or exploder, containing fulminating powder, see Arts 36, 38, &c. It may, however, be exploded by a priming of gunpowder, tightly tamped, and fired by an ordinary safety-fuse.

Art. 18. The charge should fill the cross section of the hole as completely as possible. If water is not standing in the hole, the cartridge should be cut open before insertion, so that the powder may escape from it and fill the hole; or the powder may be simply emptied from the cartridge into the hole.

Art. 19. For **blasting ice** in place, holes are cut in it, and a number of dyn cartridges (one of which must contain an exploding cap) are tied together and lowered from 1 to 5 ft into the water. They are fired as soon as possible after immersion, to avoid the danger of freezing. Electrical exploders (Arts 37, &c,) are best for sub-aqueous work.

Art. 20. Dyn is useful for **breaking up pieces of metal,** such as old cannon, condemned machinery, "salamanders" (masses of hardened slag) in blast furnaces, &c. In cannon, the dyn is of course exploded in the bore. In other pieces, small holes are generally drilled to receive it; but plates, even of considerable thickness, may be broken by merely exploding dyn upon their surface.

Art. 21. For **blasting trees or stumps,** one or more cartridges are fired in a hole bored in the trunk or roots, or under the latter. This shatters both trunk and roots. **A tree may be felled neatly** by boring a number of small radial holes into it, at equal short dists in a hor line around its circumf, and, by means of an electric battery (Arts 37, &c), exploding simultaneously a small charge of dyn in each. Or a single long cartridge may be tied around the trunk of a small tree, and fired.

Art. 22. Piles may be blasted in the same way as trees; or a hole may be bored for the cartridge in the axis of the pile; or the cartridge may be simply tied to the side of the pile at any desired ht.

Art. 23. The higher grades of dyn, like N-G, **require but little tamping.** Use a *wooden* **tamping-bar,** *never* a *metallic* one, for any explosive. If a charge of dyn "**hangs fire,**" it is dangerous to attempt to remove it. Remove the *tamping,* all but a few ins in depth, on top of which insert another cartridge, containing an exploder, and try again. See electrical exploders, Arts 37, &c. Dyn, like N-G, if frozen, must be thawed *gradually,* by leaving it in a warm room, far from the fire; or by placing it in a metallic vessel, which is then placed in another vessel containing hot water. The water should not be hotter than can be borne by the hand. Otherwise the N-G is liable to separate from the absorbent. The N-G in dyn may freeze without cementing together the particles of the absorbent; in which case the powder of course is still soft to the touch. **An overcharge** of N-G, or of dyn, is liable to be burned, and thus wasted, giving off offensive gases.

Art. 24. Dyn is sold in cylindrical, paper-covered cartridges. from ⅞ to 2 ins in diam, and 6 to 8 ins long, or longer. They are furnished to order of any required size, and are packed in boxes containing 25 lbs or 50 lbs each. The layers of cartridges are separated by sawdust.

Art. 25. Some of the **R R companies** decline to carry dyn or N-G in any shape Others carry dyn under certain restrictions, based upon State laws; providing that it must be dry (*i e,* that no N-G shall be exuding from it); that boxes and cars containing it shall be plainly marked with some cautionary words, as "explosive," "dangerous," &c; that the cartridges shall be so packed in the boxes, and the boxes so loaded in the cars, that both shall lie upon their *sides,* and the boxes

be in no danger of falling to the floor; that caps, &c, shall not be loaded in the same car with dyn, &c, &c.

Art. 26. A great many varieties of dyn are made. They differ (generally but slightly) in the composition of the absorbent, and in the method of manufacture. Each maker usually makes a number of grades, containing different percentages of N-G, &c, and gives to his powders some fanciful name.

Art. 27. The following **table of explosives,** made by the Repauno Chemical Co, Wilmington, Del, and known as "**Atlas**" **powders,** gives the percentage of N-G in each.

Brand.	Percentage of N-G.,	Brand.	Percentage of N-G.
A	75	D+	33
B+	60		
B	50	E+	27
C+	45	E	20
C	40		

The absorbents contain: in "A" brand, 18 per cent wood pulp and 7 per cent carbonate of magnesia; in "C" brand (the average grade), 46 per cent nitrate of soda (soda saltpetre), 11 per cent wood pulp, and 3 per cent carbonate of magnesia; in "E" brand, 62 per cent nitrate of soda, 16 per cent wood pulp, &c, and 2 per cent carbonate of magnesia.

Art. 28. "Miner's Friend" powder contains nitrate of soda, wood pulp, resin, and carbonate of magnesia. It freezes at 42°, and is then, like other dyn, difficult to explode. When used under water, the cartridges should not be broken, because the powder is injured by direct contact with water. Their **"Hecla" powder** is a lower grade. It is in granulated form, like ordinary blasting powder, but is said to be much stronger. It is intended as a substitute for it.

Art. 29. "Giant" powder is dyn proper, containing 75 per cent N-G, and 25 per cent Kieselguhr obtained near their works in New Jersey. The lowest grade, branded "M," contains 20 per cent N-G. The name "giant powder" was originally applied to dynamite in general.

Art. 30. Other brands are "**Hercules**" powder and "**Judson R R P powder,**" a substitute for ordinary blasting powder. It is put up in waterproof paper bags, of 6¼, 12½, and 25 lbs each, and these are packed in wooden boxes holding 50 lbs each. "**Judson F F F dynamite**" is a higher grade, in cartridges of the usual shape, packed in 50-lb boxes.

Art. 31. "Rackarock" cartridges are said to contain no N-G, and to be entirely inexplosive until immersed, for a few seconds, in an inexplosive liquid furnished by the same Co. They are then allowed to stand for 15 mins, after which they may be used at any time. They are fired in the same way as dyn, and can be used under water. The mfrs claim that they "approximate N-G in strength, and are stronger than dyn."

Art. 32. The following explosives are made and used in Europe, but have not yet been regularly imported into the U. S.

Compressed gun-cotton, is cotton dipped in a mixture of nitric and sulphuric acids, then reduced to a fine pulp, and made into discs 1 to 2 ins thick, and ⅞ to 2 ins diam, or larger. It is generally used wet, for the sake of greater safety. It then requires extra strong caps or primers. Roughly speaking, it is about as strong as dyn No 1, but is less *shattering* in its effect. Being lighter than dyn, it requires larger holes; and, owing to its rigidity, is less easily inserted, and does not fit the hole so completely. When dry, it is very inflammable, but, if not confined, it burns harmlessly. It contains no liquid, to freeze or to exude; and is safe to handle.

Art. 33. Tonite consists of finely divided gun-cotton mixed with nitrate of baryta. It is compressed into candle-shaped cartridges having, at one end, a recess for the reception of an exploder containing fulminate of mercury. The cartridges weigh about the same as dyn. They are generally made waterproof.

Art. 34. Forcite, Lithofracteur, and Dualin are foreign makes of nitro-glycerine explosives. In Dualin the absorbent is sawdust. It has greater bulk than dyn for a given wt, and requires larger holes.

Art. 35. Explosive gelatine is a transparent, pale yellow, elastic substance, and is composed of 90 per cent N-G and 10 per cent gun-cotton. It is less sensitive than dyn to percussion, friction, or pressure, and is not affected by water. Its specific gravity is 1.6. It burns in the open air. For complete detonation a special primer is required. The addition of a small proportion of camphor renders it still less sensitive, and increases its explosive force. The camphor evaporates to some extent.

In some experiments on the power of different explosives to increase the contents of a small cavity in a leaden block, explosive gelatine caused an increase 50 per cent greater than that caused by dyn No 1. In hard rock the diff would probably have been greater The increase was 10 per cent less than that caused by N-G.

Art. 36. The cap or exploder, used with ordinary safety fuse for exploding N-G and dyn, is a hollow copper cylinder, about ¼ inch diam. and an inch or two in length. It contains from 15 to 20 per cent, or more, of fulminate of mercury, mixed with other ingredients into a cement, which fills the closed end of the cap. The cap is called "single-force," "triple-force," &c, according to the quantity of explosive it contains.

The end of the fuse, cut off square, is inserted into the open end of this cap, far enough to touch the fulminating mixture in it. In doing this, care must be taken not to roughly scratch the latter. The neck of the cap is then pinched, near its open end, so as to hold the fuse securely. The cap, with the fuse thus attached, is then inserted into the charge of N-G or dyn, care being taken not to let the fuse come into contact with the explosive, which would then be burned and wasted. If a dyn cartridge is used, the fuse, with cap, is first inserted into it. The neck of the cartridge is then tied around the fuse with a string, and the cartridge is then ready to be placed in the hole and fired.

Art. 37. The Siemens magneto-electric blasting apparatus, now in general use, consists of a wooden box about as large as a transit-box. Outside it has two metallic binding-posts with screws, for attaching the two wires leading to the exploder. From the top of the box projects a handle at the end of a vert bar This bar, which is about as long as the box is high, is made so as to slide up and down in it, and is toothed, and gears with a small pinion inside the box. When a blast is to be fired, the bar is drawn up, by means of the handle, as far as it will come. It is then pressed quickly down to the bottom of the box. In its descent it puts into operation, by means of the pinion, a magneto-electric machine inside the box. This generates a current of electricity, which increases in force with the downward motion of the bar, but which is confined to a short circuit of wire *within the box*, until the foot of the bar strikes a spring near the bottom of the box, breaking the short circuit and forcing the electricity to travel through the two longer "leading wires," which lead it from the two binding-posts on the outside of the box to the cap or exploder placed in the charge.

Art. 38. The cap used with this machine is similar to that used with safety fuse (Art 36), except that its mouth is closed with a cork of sulphur cement, through which pass the two wires leading from the electric machine. The ends of these wires project into the fulminating mixture in the cap. They are ⅛ inch apart, but are connected by a platinum wire, which is so fine as to be heated to redness by the current from the battery. Its heat ignites the fulminate and thus explodes the cap.

Art. 39. Where a number of holes are to be fired simultaneously (thus increasing their effect), each hole has a platinum cap inserted into its charge, and one of the short wires attached to each cap is joined to one of those of the next cap, so that at each end of the series of caps there is one free end of a short wire. Each of these two ends is fastened to the end of one of the leading wires, placing the whole series "in one circuit." Where the holes are too far apart for the caps to be thus joined by the short wires attached to them, the ends of the latter are connected by cotton-covered "**connecting wires.**"

Art. 40. The magneto-electrical **machine weighs** about 16 lbs. It can fire about 12 caps at once.

Caps for ordinary fuse and for electrical firing, fuses, wires, electrical machines, &c, are sold by most of the makers of, and dealers in, explosives, rock-drilling machines, &c.

Art. 41. Simultaneous firing of a number of holes can be conveniently accomplished only by electricity. Electric blasting apparatus is specially useful for blasting under water, where ordinary fuses are apt, especially at great depths, to become saturated and useless.

If an electrical machine fails to fire a charge, it is known that the charge cannot explode until the attempt is repeated. Therefore no time need be lost, and no risks run, on account of "hanging fire."

GUNPOWDER.

The explosive force of powder is about 40000 lbs, or 18 tons, per square inch. Its **weight** averages about the same as that of water, or 62½ lbs per cubic foot; hence, 1 lb = about 28 cubic inches. In ordinary quarrying, a cubic yard of solid rock in place, (or about 1.9 cubic yards piled up after being quarried,) requires from ¼ to ¾ lb. In very refractory rock, lying badly for quarrying, a solid yard may require from 1 to 2 lbs. In some of the most successful great blasts for stone for the Holyhead Breakwater, Wales (where several thousands of lbs of powder were usually exploded by electricity at a single blast,) from 2 to 4 cubic yards solid were *loosened* per lb; but in many instances not more than 1 to 1½ yards. Tunnels and shafts require 2 to 6 lbs per solid yard; usually 3 to 5 lbs. Soft, partially decomposed rock frequently requires more than harder ones. Usually sold in kegs of 25 lbs.

Weight of powder in one foot depth of hole.

Diameter of hole	1 in	1¼ ins	1½ ins	2 ins	2½ ins	3 ins
Weight of powder avoirdupois	0lb 5oz	0lb 8oz	0lb 11oz	1lb 4oz	2lb	2lb 13oz
Diameter of hole	3½ in	4 ins	4½ ins	5 ins	5½ ins	6 ins
Weight of Powder avoirdupois	3lb 14oz	5lb 0oz	6lb 6oz	7lb 14oz	9lb 8oz	11lb 5oz

PRICE LIST

For a work of this kind, any attempt to present a list of exact or even of closely approximate prices would be useless. We aim merely to give indications of the average costs or of the ranges of cost. On account of the extreme reluctance or refusal of many dealers and manufacturers to submit figures, it has been impossible to give any figures at all for many items that the engineer may need. In general, the figures given represent normal prices prevailing during 1925 and 1926. Caution:—Prices in Gulf or Southern cities are often or usually quite considerably higher than those given.

Abbreviated Outline of Classification.

(See also in Index of this book.)

For principle of classification, see Bibliography, p. 1420.

PRICE LIST.

1.0 Materials and Elementary Shapes.

1.1 Chemicals, etc.

Sulfate of aluminum, $1.45 per 100 lbs.*
Sulfate of copper, $4.45 per 100 lbs.
Soda ash, 58%, $1.25 per 100 lbs.
Hypochlorate of lime, $2.00 per 100 lbs.
Chlorine, liquid—, $4.50 per 100 lbs.

*Engineering News-Record, 1925.

1.13 Preservativs.

1.131 Paints.

0.5 cts per sq ft per coat of paint.
Paints, in oil, $2.50 per gallon.
In cents per pound:
Lead: white foreign, 18; American (white), 14 to 15; red foreign, 20; red American, 14.
Zinc oxide, American, 18; Paris, 20 to 25; Antwerp, 16 to 20.
Note; foreign material subject to duty
Lampblack, 25 to 40 cts per lb.
Colors cts per lb.
Blue Chinese, 100. Prussian, 60. Ultramarine, 40.
Brown Vandyke, 25 to 30. Greene Chrome, 30 to 35.
Sienna, Burnt—, 30 to 35 Umber burnt raw, 30 to 35.
Metal coatings, $3.00 to $5.00 per gal.
Fillers, Oils, etc., $0.60 to $1.00 per gal up to $2.00
Linseed oil, $1.00 to $1.20 per gal.*
Turpentine, $0.90 to $1.20 per gal.
Plain varnish, $2.00 to $2.50 per gal.
Linseed varnishes, $3 per gal.
Shellac, $3 per gal
Graphite pipe joint compound, 24 cts per lb.

1.132 Creosoting, Impregnating, etc.

Creo-resinate and creosote process, 15 to 25 cts per cu ft.
Creosoting varies from 25 to 40 cts per cu ft of material for various degrees of saturation. Subject to market price fluctuations

1.14 Explosives.

Gunpowder, 20 cts per lb. Smokeless powder, 60 cts per lb.
Dynamite, 15 to 25 cts per lb for grades varying between 20 and 75% nitroglycerin.*
Blasting caps, $7 00 per 1000.

1.2 Wood, Lumber, Timber.

Lumber in dollars per 1000 ft B.M. (Board Measure)
Black walnut, 250.
Douglas fir, 30 to 50 and 75, varying with location.
Hemlock, 33 to 75.
Long leaf yellow pine, 3″ x 4″ to 12″ x 12″, 48 to 56.
12″ x 12″ to 16″ x 16″, 56 to 71.
Southern pine, 57. Spruce, 35 to 88.
White ash, 130. White oak, 180.
Yellow pine, 25 to 60, average, 35 to 40.
Yellow poplar, 85 to 130.
Shingles, Cypress—, 5 to 10 cents per sq ft.
Red cedar—, 6 to 7 cents per sq ft.
Asbestos and composition—, see 1.9.
Clearing and grubbing, see 2.11.
Piles, see 1.23. Ties, see 9.14.

1.23 Piles.

Piles, 50 to 70 cts per lineal foot.
Piling, round or sheet—, 70 to 125 cents per lineal foot

1.3 Stone, Concrete, Asphalt.

Earthwork, Dredging, Foundations, see 2.1.

1.31 Road Materials.*

Cents per gallon, carload lots,
Binder, 7, Flux, 7, Liquid Asphalt, 7. See also 1.33.
Granite Blocks (28 to 30 per sq yd) $132 to $142 per 1000
Flagging, 4″ to 5″ wide, 25 cts per sq ft.
Curbing, $1 per lineal foot.
Wood block, $2 00 to $2.85 per sq yd.
See also 1.33, Asphalt.

*Engineering News-Record, 1925.

1.32 Stone.

Sand, $1.00 to $1.60, southern cities, $2.00 per cu yd.*
Gravel, $1.50 to $2.25 per cu yd, southern cities, $2.50 or more.
Broken stone, $1.10 to $2.50 per cu yd.*
Trap rock, $2.00 per ton at quarry
Ordinary building stone, $3 to $10 per cu yd
Granite, $25 to $75 per cu yd.
Roofing slate, No. 1 ribbon, 11½ cts per sq ft.
Slag roofing, $1.50 to $2.50 per ton in carload lots
Slag, crusht—, carload lots, $1.30 per cu yd *

1.33 Asphalt.

5 to 7 cts per gallon.*
Mexican—, bulk, $18 to $23 per ton, in packages, $23 to $27 *
Texas —, bulk, $21 to $25 per ton; in packages, $27.
Paving, see 2.4.

1.34 Cement, Lime, Plaster, etc.

Sand, see 1.32
Natural cement, $1.35 to $2.80 per bbl, for 500 bbls or over, exclusiv of bags.*
Portland (artificial) cements, $2 15 to $2.60 per bbl in carload lots, exclusiv of bags.*
Bags, 10 cts each, 40 cts per bbl.*
Lime, lump—, $1.50 to $3 50 per bbl.
Hydrated lime, $15 to $25 per ton.*
Plaster, $2.25 to $3.50 per bbl.
Gypsum plaster, neat, $20 per ton.
Plaster board, see 1.9.
Concrete construction, see 2.35.

1.35 Brick, Tile, Glass.

Sewer pipe, see 9 255.

1.351 Brick.

Paving, see 2.4
Building brick per 1000.
Common—, $12 to $20.*
Salmon—, $18 to $22. Hard—, $22 to $25. Dressed—, $30 to $55 Colored—, $35 to $60. Iron spots—, $60.
Fire brick, $40 to $55.
Vitrified paving brick, $25 to $45.

1.352 Tiling.

Hollow tile, 8" x 12" x 12", carloads, 11 to 20 cts per block;* smaller lots, 15 to 30 cts
Roofing tile, $15 to $50 per 100 sq ft.

1.4 Iron and Steel.

(Freight rates, cts per 100 lbs, from New York City, in carloads of 36,000 lbs; to Baltimore, Md., 31 Birmingham, Ala., 58, Boston, 37; Buffalo, 27, Chicago, 34, Cincinnati, 29; Detroit, 29; Kansas City 74; New Orleans, 67; Norfolk, 34; St. Louis, 43, St. Paul, 60.)

1.41 Cast Iron and Steel.

Cast iron pipe, see 9.251.
Pig iron per ton of 2240 lbs at foundry, $40. Bessemer—, $40 to $50 Gray Forge—, $40, Lake Superior Charcoal—, $45 to $55.

*Engineering News-Record, 1925.

1.43 Rolled and Structural Iron and Steel.

Iron and Steel:—Refined iron bars and steel bars, angles, ordinary sizes, T-shapes, beams and channels, structural shapes, tank plates, structural plates, bessemer machinery steel, 3 to 4½ cts per lb.*

Reinforcing bars, dollars per 100 lbs, warehouse,*

Size	¾″	½″	¼″
From	3.00	3.20	4.00
To	3.50	3.50	4.25

Expanded metal

Pounds per sq ft,	0.25	0.50	1.02	2.04
Cents per sq ft,	11	8	7	7

Metal lath, 4 cts per sq ft.

Steel rails, see 9.11.

1.431 Sheet and Plate Iron and Steel.

Gage,	14 to 16	22	25	28	29	30
Cts per lb,	30 to 33	35	40	42	47	52

Discount, 50%.

Blue anneald—, 3½ to 4 cts per lb.

Black iron, 4 to 4½ cts per lb.

Galvanized iron sheets, 4 to 4½ cts per lb.

1.45 Fastenings.

1.451 Nails and Spikes.

Nails, $3.50 to $4.50 per keg.

Spikes, railway—, 4 cts per lb.

1.452 Rivets.

⅜″ and 7/16″, 7 cts per lb.

½″ and larger, 6 cts per lb, to as low as 2.6 cts per lb in carload lots.

1.454 Bolts and Nuts.

Bolts and nuts (machine) per 100, square or button heads, length under head, 2″. Discount, 50%.

Diam in inches,	¼	½	¾	1
Dollars per 100,	2 40	7.80	17.00	35.00
Extra per inch over 2″,	0 80	0.60	5.00	12.00

1.455 Turnbuckles.

Discount, 60%.

Size	Take-up in inches	Price
¾″	12	$2.00
¾″	24	$5.30
⅞″	12	$3.40
⅞″	24	$6.40
1″ to 2″	48	$42.00
1″ to 2″	72	$52.60

*Engineering News-Record, 1925.

1.457 **Chains.**

American coil chain,

Inches,	$\frac{3}{16}$	$\frac{1}{4}$	$\frac{3}{8}$	$\frac{1}{2}$	$\frac{7}{8}$
Cts per lb,	20	15	10	9	8

1.46 **Tubes.**

See 9.25, &c.

1.47 **Wire, Wire Rope, Fencing.**

Hoisting and conveying machinery, see 3.5.

1.471 **Wire.**

Hoisting Rope, extra strong cast steel, 5½ cts per ft length per ton of working load, for diams 1″ to 2¾″. 6½ cts per ft length per ton of working load for diams as small as ½″.

Extra pliable, 6½ to 8½ cts per ft per ton of working load, for diams 2¾″ to 1″.

1.472 **Wire Fencing.** 75 cts to $2.00 per 16½ ft length.

1.473 **Wire Rope.**

60 cts per sq inch of cross section per ft of length

See also 1.471.

1.5 **Other Metals and Alloys.**

Sheet brass, 30 to 60 cts per lb, depending upon width.

Soft copper, 60 cts per lb.

Pig lead, 9 cts per lb. Galvanizing, 2 cts per lb.

1.6 Paper.
Tar—, $2.00 to $2.25 per roll of 108 sq ft.
Tard felt, $2.50 to $3.25 per roll.
See also 1.9, Other Materials.

1.7 Ropes.
Wire ropes, see 1.471-3.
Manila, plain or tard, 25 cts per lb. Sisal, 20 cts per lb.
Twine, 15 cts per lb. Oakum, 12 to 15 cts per lb

1.8 Packing, Gaskets, Belting.
Rubber belting, cts per ft one inch wide,
2-ply, 6; 3-ply, 8; 4-ply, 9.
Leather belting,

width, ins,	1	6	12	24	72
$ per ft,	0.09	0.82	2.00	5 00	20.00

Pipe jointing supplies, see 3.263.

1.9 Other Materials.
Gypsum plaster board, $^3/_8$", $45 to $50 per 1000 sq ft.
Tar felt, 14 lbs per 100 sq ft, $84 per ton.
Tar pitch, $1.85 per bbl. Asphalt roofing, $38 per ton.
Asbestos shingles, 15 to 29 cts per sq ft.
Composition shingle, crusht slate surfaced, 6 to 7 cts per sq ft.

2.0 Constructions.
Waterworks supplies, see 9 2.
Railroad Supplies, see 9.1.

2.1 Earthwork, Dredging, Foundations.

2.11 Excavation and Embankment.
See also page 1024, etc.
Clearing and grubbing, $50 to $250 per acre.
Earth excavation, $0.50 to $2.50 per cu yd. In trenches, $2.00 up, according to depth.
Rock excavation in large masses, $1.25 to $4.00 per cu yd In small or difficult places up to $8 per cu yd.
Embankment, $1 to $3 per cu yd
Rock filling, $3 to $8 per cu yd.
Sodding, $0.60 to $1.00 per sq yd.

2.12 Dredging.
10 cts to $2.00 per cu yd, according to material, haul, etc.
See also p. 581w.

2.13 Foundations.
Piles, see 1.23.

2.2 Masonry.

2.21 Brick Masonry.
$10 to $15 per 1000 plus cost of bricks.
Brick chimneys, dollars equal 8.3 x height x diam (in feet) for abt 50′ ht, to 5.2 x height x diam (in feet) for abt 200′ ht.
Bricks, see 1.351.

2.22 Stone Masonry.
Rubble, dry, $4 to $15 or more per cu yd.
in cement, $7 to $20 per cu yd.
Granite coping, $50 to $70 per cu yd
Plain cellar masonry, $8.
Stone, see 1.32.

2.23 Concrete and Cement Masonry.
In place, dollars per cu yd,—
Class A, 18 to 30; Class B, 14 to 20; Class C, 11 to 18; Class D, 8 to 10.
Walls and chambers, $12 to $15 per cu yd.
Floors and Sidewalks, $9 to $11 per cu yd.
Cement, see 1.34.
Concrete Mixers, see 3.64.

2.24 Plastering.
Three-coat work, \$1.25 to \$1.75 per sq yd.
Lathing, 25 to 35 cts per sq yd.
Wall board, 4 cts per sq ft, plus labor.
Sheet plaster, 6 to 8 cts per sq ft.
Wire lath and plaster partition wall, \$4 per sq yd.

2.3 Metal Structures.
3½ to 4½ cts per lb.

2.33 Tanks, Stacks, etc.
Pipes, see 9.25.
Standpipes, 22 x 60 ft, including foundations, \$12,000.

2.34 Boilers.
Upright tubular boilers with base and fixtures.

IHP	4	12	30	50	200
\$	300	450	700	900	3000

2.35 Fireproofing, Concrete-Metal Construction.
Covering colums and girders, 50 cts per sq ft.
Walls, \$1 40 to \$3 00 per sq yd.
Wall furring, 80 cts to \$1 25 per sq yd
Metal lath, etc., see 1.43.

2.4 Paving.
Dollars per sq yd.

Asphalt, 3 to 4.50.	Belgian Block, 3.50 to 5.00.
Brick, 2 to 2 75	Macadam, 1.25 to 2.00.
Cellar floors, 2 25 to 3.75.	Sidewalks, 2.00 to 5.50.

2.5 Sewers.
From 6″ to 18″ diam, dollars per ft run.

Depth below surface	5 ft	10 ft.
Excavating only	\$0.60 to \$2.00	\$1 to \$3.

Laying pipe, exclusive of excavating, per ft.
15 inch, \$0.50 to \$1 00. 4 inch, \$0 40 to \$0.80.
Brickwork in sewers, \$25 per cu yd.
Excavating, using large excavator, 7 ft deep, 20″ wide, 60 cts per ft of length, or 5 cts per cu ft.

2.7 Roofing.
Asbestos, 40 cts per sq ft
Shingle, 25 cts per sq ft
Slag, 10 cts per sq ft and up.
Slate, 20 cts per sq ft and up.
Skylights, \$1.10 per sq ft and up.

3.0 Machinery.

3.2 Tools, Machine Tools.

3.21 Hammers.
Riveting, \$65; chipping, \$50. Concrete breaking tool, \$165.

3.23 Drills.
Portable electric drills, for metal, from \$25 for $\frac{5}{16}$″ hole to \$200 for 1½″ to 2″ hole.
Pneumatic stone drills, \$12 to \$17.
Air drills, \$80 to \$200, according to capacity.
Rock drills.

Depth of hole, ft.	1	10 to 15	25 to 35
Price,	\$200	\$300	\$400

Electric hammer drills, for holes in stone, from \$150 to \$225 for 2″ holes.
Diamond rotary drills,

Depth of hole, ft.	4000	1500	1000	800
Boiler HP	25	15	12	10
Price	\$8000	\$5000	\$3500	\$3000

Explosives, see 1.14

3.26 Pipe Cutting, Tapping and Jointing Machinery.

3.262 Tappers.
Dry pipe, \$30 to \$50 each. Under pressure, \$125 and up.

3.263 Jointers.

Diam, ins	2	12	36	72
Price, each	\$3	\$15	\$25	\$50

3.3 Engines.

Pumps, see 3.4. Boilers, see 2.34.

Portable engines, 10 HP, $600 and up. 25 HP, $850 and up. 50 HP, $1300 and up.

3.31 Stationary and Hoisting Engines.

Air Hoists, geared, from $200 for 1-ton cap,. to $800 for 10-ton.

From $25 to $35 per IHP for medium sizes.

Single cylinder stationary engines,

HP	12	30	50	100	200	300
Price,	$840	$1500	$1700	$2400	$4000	$6000

3.4 Blowing and Pumping Machinery.

3.41 Compressors.

Portable gasoline-driven compressors, from $1200 to $1400 for 100 cu ft of free air per min, to $3500 for 300 cu ft

3.45 Hydraulic Rams.

$3 to $5 times square of diam of drive pipe in inches.

3.46 Pumps.

$25 to $50 per HP.

For unwatering excavations, $100 to $135 per HP

Pulsometers, $25 to $45 per HP

Artesian well cylinders (not including the pump at the surface),

Cap, gals per stroke,	¼	½	1	2	4	7	10
Price	$20	$35	$75	$140	$250	$400	$1200

Centrifugal, $20 to $30 per HP

3.5 Hoisting and Conveying Machinery.

Belt conveyors, portable, $500 to $1800.

Bucket loaders, about $4000.

Electrical—, see 3 1.

Excavating machinery, see 3.6.

Hoisting engines, see 3.31

Wire rope, see 1.473.

3.54 Elevators, Hoists, Derricks.

Hoisting crabs, on winches, ½ to 2½ tons cap, $70 to $150.

Differential hoists, ¼ to 3 tons, $35 to $90.

Derrick, guy—,

10-ton capacity, $400 to $800.

20-ton capacity, $800 to $1700.

Derrick, stiff-leg, hand-power, 1-ton, $200

Derrick, stiff-leg, without hoisting or power devices, 10-ton, $750; 20-ton, $1400

Derrick, stiff-leg with bull-wheel, 10-ton, $1200, 20-ton, $2300.

Hand winches, pull of 2 men on single line, 900 lbs, $60, 3000 lbs, $80 to $150.

Electric hoist, without motor, double friction drum. Pull on line, 3000 lbs, $1400 to $2500, 12,000, $9,000

Steam hoisting engine, drum—, without boiler,

HP,	8	20	45
	$1000	$1500	$2400

3.6 General Construction Machinery, Excavators, etc.

Hoisting and conveying, see 3.5. Hoisting engines, see 3.31 Drills, see 3.23. Explosives, see 1.14. Excavation and Embankment, see 2.11.

Trucks or trailers average $250 each.

3.61 Trench excavators.

Trench Excavators, $5500 to $12,000.

3.62 Pile Drivers.

Pile Drivers, $500 to $2500.

3.63 Shovels, Scrapers, Plows, etc.

Steam shovels, about $10,000 each.

Wheeled Scrapers, $40 to $60 each.

Drag scrapers, $10 to $15.

Plows up to $55 each. Hardpan plow, $70.

3.64 Concrete Mixers.

Concrete mixers, $300 to $1500.

3.65 Diving and Diving Apparatus.

Complete outfit. For shallow water, $300; for moderate depths, $600; for deep sea, $1000.

3.66 Cement Guns.

Cement gun only, $7 to $14 per cu ft of free air per min.
Compressors, see 3.41.

3.67 Wells and Well Driving Machinery.

Well strainers, $2 to $4 per lin ft per inch diam of pipe up to 10″ diam.
Foot valves, $2 to $10 per inch diam inside of well casing, 2″ to 10″.
Drills, see 3.23.

3.68 Road Making Machinery.

3.681 Rollers.

Tandem, $2500 to $4500. Three-wheel, $2500 to $7500.

3.683 Rock and Ore Crushers.

Receiving Cap, ins	Capacity tons per hr	HP required	Cost, dollars
8 x 14	10 to 15	10 to 12	1000
10 x 18	16 to 24	15 to 20	1500
14 x 36	45 to 60	60 to 75	5500

Concrete mixers, see 3 64.

4.0 Engineering, Surveying and Scientific Instruments and Supplies.

Aneroid barometers, $36.
Current meters, $65 to $300.
Direction meters, $200 to $250.
Velocity register and time-piece, $15 to $60.
Hook gages, $15.
Thermometers for asphalt and sand, $3 to $5.25.
Maximum—, $4

4.2 Surveying Instruments.

4.21 Transits, Plane Tables, Compasses, etc.

Transits, plain, $250 to $300.
Engineers' complete transits, $300 to $500.
Mining transits, $300 to $400 and up to $750.
Mountain transits, $150 and up to $400.
Theodolites and portable alt-azimuth astronomical instruments, $600 to $1200.
Solar attachments, $60 to $80.
Sextants, $70 to $150. Pocket sextants, $60
Plane tables, complete, $100 to $450.
Compass, pocket—, $15 to $30

4.22 Levels.

Engineers' levels, $125 to $225.
Hand levels, $6 to $20, usually about $10.

4.23 Rods, Tapes, etc.

Leveling rods, $15 to $20 each.
Range poles, $3 to $6.
Tapes from 6 to 30 cts per ft, depending upon graduations and length.
Chains, 8 to 12 cts per ft.

4.3 Computing Instruments.

Planimeters, $15 to $375, average, $40.
Slide rules, Mannheim, $5. Other forms, $8 to $12 and up to $50.
Computing machines, $100 to $300, and special electric drive up to $700.

4.4 Drawing Instruments and Materials.

Drawing paper, "detail," 15 cts to 20 cts per sq inch of sheet per ream.
Tracing paper, 42″ wide, 4 cts to 12 cts per yd.
Cross-section paper, 8½ x 11, $1.35 per 100 sheets.
Drawing instruments, $10 to $30 per set—very elaborate sets up to $100.
Drawing pens, $1 to $3 each.
Compass, $3 to $9. Dividers, $1.50 to $4 50.
Triangular boxwood scales, 12″, $1 to $3
Metal straight edges, 36 inches long, $3 to $5
T-Squares, 36″ with celluloid edges, about $2.25. wood, $1 to $2.40; steel, $7 to $10, usually with adjustable angle.
Triangles, celluloid. 6″, 40 to 65 cts. 12″, $1 to $1 50
French curves, celluloid, $0 50 to $1 50
Protractors, German silver, 4″, $0.50 to $2.00; 6″, $1.50 to $5, with arms 6″, $9; 8″, $12.
Drafting machines, $60 to $125.
Drawing inks, 25 cts per bottle.

4.5 Heliography.

Blue prints, 2 to 3 cts per sq ft.
Blue print paper, 1¼ to 2 cts per sq ft.

9.0 Miscellaneous Supplies.

9.1 Railroad Supplies.

9.11 Rails.

Steel rails, standard, $43 per ton; Light (8 to 45 lbs), $30 to $36, Rerolled, $28,* Old, $25 per ton.

9.12 Joints.

3 to 5 cts per lb.

9.14 Ties.

Chestnut, $3 each, White Oak, $1 to $2 each; Yellow Pine, $1.50 to $2 00 each; Douglas fir, $1.
Miscellaneous treated ties, about $1 50 to $2 each.
Tie plates, 10 to 30 cts each.

9.15 Spikes.

Spikes, 2¼ to 4 cts per lb.*

9.16 Bolts.

Bolts, 3¾ to 6 cts per lb.

9.17 Angle Bars.

Standard section angle bars, 2¾ to 4 cts per lb.*

9.2 Hydraulic Supplies.

Gaskets, see 1.8.
Stand Pipes, Tanks, see 2.33.
Pipe Cutting and Tapping Machines, see 3 26.

9.23 Chlorinating Apparatus.

Chlorinator, $400 to $800.

9.24 Water Meters.

80 cts to $1.20 per gal per min.
From ⅝″ to 1″, $12 to $27; 2″, $61 to $72; 4″, $205 to $240; 6″, $360 to $407; 10″, $825, 16″, over $2000.

9.25 Pipe.

Pipe Cutting Machinery, etc., see 3.26.
Pipe laying, see 3.6.

9.251 Cast Iron Pipe.

$40 to $60 per ton.

9.252 Steel Pipe.

Steel Pipe at works, 5½ cts per lb.
Spiral rivetted—, plain end, dollars per foot.

Diameter	3″	6″	12″	18″	24″	30″
From	0.24	0.57	1 45	2.75	3.70	5.90
To	0.34	1.10	2.82	4.30	5.70	7.10

depending upon thickness or strength.
Asphalted, 10% more for large sizes, 25% more for small.
Galvanized, 35% more for large sizes, 55% more for small sizes.

*Engineering News-Record, 1925.

9.253 Wrought-Iron Pipe.

Wrought Iron Pipe, 15 cts per lb.

Ingot Iron Culverts, dollars per foot,

Diam,	8″	15″	20″	24″	36″	42″	48″	60″	72″	84″
From	1	1½	2	3	5	5½	6	10½	12½	18
To	•				6	7	8½	13½	15½	22½

9.254 Wood Pipe.

Machine Banded 50 ft head, 10 cts per inch per ft diam.
100 ft head, 20 cts per inch per ft diam

9.255 Sewer Pipe.

Drain Tile, dollars per thousand lineal feet,*

Size	3″	4″	5″	6″	8″
From	40	40	70	70	160
To	50	70	100	130	200

Sewer Pipe, dollars per foot, standard pipe.*

Size	3″	6″	12″	18″	24″	30″	36″
From	0.10	0.13	0.36	0.65	1.21	2.66	3.95
To	0.12	0.21	0.66	1.53	2.16	3.75	5.42

9.256 Hose.

Water Hose, cents per inch of internal diam per ft of length,

2-ply	4-ply	6-ply
25	40	60

Air, Hot Water and Steam Hose, cts per inch of internal diam per ft of length,

4-ply	6-ply	8-ply
75	110	140

*Engineering News-Record, 1925.

9.26 Valves.

Single or double gate valves, iron body, bronze mountings.

	Pressure, lbs per sq in.		
Tested to	200	400	600
For Water	100	250	400
For Steam	35	125	250
Diameter	Approximate prices in dollars, without discounts.		
2"	6- 7	8- 15, 23	11- 27, 35
6"	28-31	32- 50, 65	50-100, 115
12"	75-82	115-185, 215	150-335, 390
Working pressure, lbs/sq in,	30-40,		100-125.

Diameter	Approximate prices in dollars.	
18"	150	470 (double gate)
36"	700	

Check valves, Horizontal swing.

Working pressure, 100 lbs/sq in for steam.
175 lbs/sq in for water.

Diameter,	½"	1"	2"	4"	6"	12"	18"	24"	36"
	Prices each in dollars.								
Screwed ends,	1.40	2.15	8.50	20-37	31-43	97-175	230	400	1900
Flanged ends,	3.40	4.15	14.00	21-47	33-45	95-170	225	390	1900

for Working pressures of 250 lbs/sq in for steam,
400 lbs/sq in for water,
increase figures above by 20% to as high as 45% for small sizes.

Fire Hydrants. From $20 for 2" valv and one 2" nozzle, to $50 for 6" valv and three 2½" nozzles

9.9 Labor.

Bricklayers.*† $1.55 per hour in a belt about 400 miles wide, from Springfield, Ill., to New York, with maxima of $1.75 at those two cities, diminishing to $1.63 in Colorado and $1.30 on Pacific coast. Southern States and upper Lake region, about $1.25.

Carpenters.*† $1.50 per hour in a belt about 200 miles wide from New York city to central Illinois, and about $1.60 in Colorado, grading off to $1.00 on the Pacific coast, and down to $0.70 or less in the east Gulf states $1.00 in the Lake region.

Structural Iron Workers.*† $1.50 per hour from Illinois to New York city, except Ohio about $1.35, tapering rapidly to $1.10 and $1.00 on the Great Lakes, and to $0.80 in Georgia. New Orleans is exceptional with $1.25. West of Mississippi R to Pacific coast, about $1.10.

Common Labor.* $0.80 to $0 90 from Chicago to New York city, grading down to $0.30 in Georgia and Alabama, and to $0.60 on the Great Lakes. West of Mississippi R, $0.50 to $0.60.

According to Bureau of Labor Statistics, on May 15, 1925, the following averages were in effect:—Plasterers, $1.485; Plasterers' laborers, $1.00, Bricklayers, $1.475, Stone Masons, $1.401; Slate and Tile Roofers, $1.419, Tile Layers, $1.325; Lathers, $1.398, Plumbers, $1.281; Plumbers' laborers, $0.954; Inside Wiremen, $1.272; Steamfitters, $1.271; Structural Iron Workers, $1.271; Hoisting Engineers, $1.265; Cement finishers, $1.238; Painters, $1.232; Sheet Metal Workers, $1.209; Carpenters, $1.184 Building laborers, $0.954.

*Engineering News-Record, 1926, July 1.
†About 5 to 10% higher in 1928.

BIBLIOGRAPHY

The following list of books makes no pretensions to completeness It aims simply to be usefully suggestiv to the general civil engineer. The list is arranged according to the Decimal Classification of Melvil Dewey. In this classification (see outline below) all subjects are arranged under ten general heads, and to each of these heads is assignd a number in the hundreds place, as Natural Science, 500; Useful Arts, 600, etc. Then each general head is divided into ten subheads, to each of which a number in the tens place is assignd Thus Natural Science (500) is subdivided into Mathematics, 510; Astronomy, 520; Physics, 530; etc Again, each of these is subdivided, and decimally numberd, and this successiv subdivision and decimal enumeration may be continued indefinitely. **To find a subject**, refer to the table below, and decide, first, under which of the general heads it belongs, then under which sub-head, and so on Thus, Plane Geometry is seen to belong (1) under Nat Sc, 500, (2) under Math, 510, and (3) under Geom, 513. However, matter on a special subject is often containd in books on a more general subject which embraces the special one Thus, matter pertaining to Geom (513) is found in many works which would be classified under Mathematics (510) Conversely, in looking for books on Mathematics, the sub-heads, Algebra, Geometry, etc. should be consulted as well. In general, it is advisable to look under all heads that may contain the information wanted. Thus, information on Locomotivs may be found under Mechanical Engineering, 621, or under Railroads, 625. To avoid duplication in such cases, however, one such head has usually been selected, and reference to it made under the other.

Outline of Classification.

000	**GENERAL**	622	**Mining, Exc'v'n,** etc
500	**NATURAL SCIENCE**	622 26	Tunneling
510	**Mathematics**	622.32	Hydraulic Mining
512	Algebra	624	**Bridges and Roofs**
513	Geometry	624 2	Girders
514	Trigonometry	624 3	Trusses
515	Descriptive Geometry	624 6	Arches
516	Analytical Geometry	624 8	Draw Bridges
517	Calculus	624 9	Roofs
519	Probabilities. Least Squares	625	**Railroads** and Roads
		625 1	Route Track
520	**Astronomy**	625 1a	R. R Surveying
526	Geodesy	[illegible] 2	Trains. Cars
526.9	Surveying	625.8	**Roads & Pavements**
530	**Physics**	[illegible] 7	**Hydraulic** Eng
531	Mechanics	[illegible] 8	Irrigation
532	Hydromechanics	627.7	Dredging
533	Pneumatics	627 8	Dams
536	Heat	628	**Sanitary** Engineering
537–8	Elec'y and Magnetism	628.1	**Water Works**
540	Chemistry	630	Forestry
550	Geology	660	Chem. Tech'y Explosives
600	**USEFUL ARTS**	670	Manufactures Iron & St'l

Book Sizes

The following book sizes have been recommended by the American Library Association —

Name	32mo	24mo	16mo	12mo	8vo	4to	Folio
Ht. ins	4 to 5	5 to 6	6 to 7	7 to 8	8 to 10	10 to 12	12 to 14

When width is 3/5 height, book is called "narrow"; ¾ height "square"; = height "oblong."

000 General.

Allen, C F. Business **Law** for Engineers. 456 pp. 6 x 9. Buckram $4 00 McG

Whipple, G C—. **Vital Statistics.** 2nd ed, revised and enlarged. 579 pp 89 ills. 4½ x 6¾ Flexible. $4 00. 1923. W.

500 Natural Science.

510 Mathematics.

Claudel, J.— **Handbook** of Mathematics Translated and edited by O. A. Kenyon. From the 7th French edition. 708 pp. 422 ills. $3.50. McG

Huntington, E. V.—. **Handbook** of Mathematics for Engineers. A reprint of sections I & II of Marks' Mech. Engr's. Handbook. 191 pp. 5 x 7½. Flexible. $1.50. 1918. McG.

Rose, W. N.—. Mathematics **for Engineers.** Part II. 433 pp. 130 ills 5¾ x 8¾. Cloth $7.00. 1920. VN

Webber, W P.—. **Elementary Applied** Mathematics. 115 pp. 5¼ x 8 23 ills. Cloth. $1.25. W.

Wynne, W. E—, and Sparagen, Wm—. **Handbook** of Engineering Mathematics 2nd ed. revised and enlarged. 290 pp. Illd. 4½ x 6¾. Flexible Fabrikoid $2.50. 1920. VN.

510.8 Tables and Mathematical Instruments.

Barlow. Barlow's Tables of **Squares, Cubes,** Square **Roots,** Cube Roots, **Reciprocals** of all Numbers up to 10,000. 200 pp. 12mo. Cloth. $1.25. 1905. SC.

Bruhns, C.—. New Manual of **Logarithms** to Seven Places of Decimals. 9th ed. 633 pp. 7 x 10. Cloth, $2.00. Half Morocco, $2.50. VN.

Chambers. Chambers's Mathematical Tables, consisting of **Logarithms** of Numbers 1 to 108,000, **Trigonometrical,** Nautical and Other Tables. 8vo. Cloth. $1.75. VN.

Hering, Carl—. Ready **Reference** Tables. 196 pp. 4¼ x 6¾ Flexible. $2.50. W.

Hewes, L. T.—, and Seward, H. L.— Design of **Diagrams,** and the Theory of **Nomography.** 112 pp. 82 ills. 9 x 12 $5.00. 1923. McG.

Lipka, Joseph—. **Graphical and Mechanical Computation,** Vol. I, Alignment Charts, 122 pp. Vol. II, Experimental Data, 145 pp 205 ills. 6 x 9. Cloth. $2 per vol. W.

Molesworth, W. H.—. **Metrical** Tables. 4th ed, revised and enlarged. 95 pp. 3 x 5. Cloth. $0.75 1918. SC.

Pickworth, Chas N.—. The **Slide Rule.** 12th ed. 118 pp 34 ills. Table. 5 x 7¼ Cloth. $1.00. VN, Whittaker & Co. and Emmott & Co, London

vonVega, Baron - **Logarithmic** Tables and Numbers and **Trigonometrical** Functions. Translated by W. L. F. Fischer, 603 pp. 6 x 9 Cloth. $2.00 Half Morocco $2.50. VN

Tables. See also under subject in question, as Surveying, 526.97, etc.

512 Algebra.

Chrystal, G.—. Algebra

Wentworth, G. A.— Complete Algebra. 525 pp. 12mo Half Morocco. $1.72. G.

513 Geometry.

Chauvenet, Wm—. Geometry L.

Wentworth, G. A—. Plane and Solid Geometry. Revised ed 473 pp. Illd 12mo. $1.60 G

Analytical Geometry, see 516

Descriptive Geometry, see 515.

Drawing, see 740.

514 Trigonometry.

Buchanan, A H.— Plane and Spherical Geometry 5¾ x 9¼. Cloth. $1.00. W

Rider, Paul R— and Davis, Alfred –. Plane Trigonometry 291 pp. Illd. 5½ x 8 Cloth. $1.90. 1923 VN.

Wentworth, G. A—. Plane and Spherical Trigonometry. 232 pp Illd. 12mo. Half Mor. $1.44. G.

515 Descriptive Geometry.

Blessing, G. F —, and Darling, L. A. . **Elements** of Descriptive Geometry. 247 pp 6 x 9 187 ills Cloth. $2.50. W

620.c Civil Engineering.

Gillette and Dana. (Separately and jointly) Over a half dozen books on **Construction Cost Keeping Data,** etc. From 572 to 1854 pp. Various sizes Illd Mostly $6 00

Grant, H. D—. Practical **Accounting** for the Contractor. 254 pp. 46 forms. 6 x 9. $3 00 McG.

Hütte, Verein -. Des Engineurs **Taschenbuch.** Vol III: Hutte des Bauingenieurs 21st ed 4½ x 7¼. Cloth. $3 60 Leather, $4 00 Wilhelm Ernst & Sohn, Berlin, Germany

Merriman, Mansfield—. American Civil Engineer's **Handbook.** 4th ed. 1955 pp. Illd. 4¼ x 7. Atho-leather, $6.00. Real Leather, $7.00. W.

Lewis, N. P.—. The **Planning of the Modern City.** 2d ed. revised. 474 pp. 6 x 9. 62 ills and 87 full-page plates. Cloth. $5.00. W.

McGraw-Hill Co Engineering News-Record. **(Weekly Periodical).** 9 x 12. $5 00 per year. McG.

621.13 Locomotives.

Forney, M. W.—. Catechism of the Locomotive. See Fowler, G. L.—.

Fowler, G. L.—. Forney's **Catechism** of the Locomotive. 3d ed, revised and enlarged. Part I. 644 pp. 475 ills. 6 x 9. Cloth. Part II. 293 pp. 199 ills. 6 x 9. Cloth McG

Wright, R. V.— and Augur, R. C—. Locomotive **Cyclopedia.** 1115 pp. 2588 ills. 9 x 12. Cloth, $8.00 Leather, $10.00. 1925. S-B

Electric Locomotives, see 621.3.

621.165 Steam Turbines.

Croft, T—. Steam Turbine **Principles and Practice.** 347 pp. 276 ills. 5½ x 8. $3.00. 1923. McG.

Moyer, J A— Steam Turbines. 5th ed, revised and enlarged. 524 pp 6 x 9 231 ills. Cloth. $4.00. 1924. W.

Roe, J. W— Steam Turbines. **Theory, Design and Field Operation.** 143 pp. 71 ills. 6¼ x 9½. Cloth. McG.

621.18 Steam Generation.

Bacon, R. S.— and Hamor, W. A—. **American Fuels.** 2 vols. 1245 pp 382 ills 6 x 9. $12.00. 1922. McG.

Brislee, F J—. An **Introduction** to the Study of Fuel. 291 pp 61 ills 5 x 9 Cloth. VN.

Dunn, J T—. **Pulverized and Colloidal Fuel.** 1924. 7 x 9½. Cloth 200 pp $6.00. VN

Kent Wm— **Steam-Boiler Economy.** 2d ed, revised and enlarged 717 pp 286 ills 6 x 9 Cloth. $6.00. W.

Marks, L. S—, and Davis, H. N—. Tables and Diagrams for the **Thermal Properties** of Saturated and Superheated Steam. 106 pp. 10 ills. $2.00 LG

Marsh, T A—. **Combustion** in the Power Plant. 266 pp. 5 x 7¾ Cloth. $2.00. 1925. VN.

Steam Heating, see 697.

621.2 Water Engines and Motors.

Church, I. P—. Hydraulic **Motors.** 8vo Cloth. W.

Marks, G. C— Hydraulic **Power** Engineering. 2d ed. 235 ills 5¾ x 8¼ $4.50. VN

Mead D W—. **Hydrology:** The Fundamental Basis of Hydraulic Engineering. 647 pp 6 x 9. Cloth McG.

Meyer, A. F.—. The **Elements of Hydrology.** 499 pp. 287 ills. 6 x 9. Cloth $4.00 W.

Hydromechanics, 532.

Hydro-Electric Engineering, see 621.2-3 below

Pumps, see 621.6.

621.2-3 Hydro-Electric Engineering.

Koester, Frank—. Hydroelectric **Developments** and Engineering. 2d ed. 475 pp 500 ills. 45 tables 7¾ x 10¾. Cloth. $5.00. VN

Muller, R— Hydroelectric Engineering. 431 pp 395 ills. 75 tables. $6.00 G. E. Stechert & Co, 151 W. 25th St., New York.

Water Engines and Motors, 621.2.

Electrical Engineering, 621.3.

621.3 Electrical Engineering.

Drysdale, C V.— and Jolley, A C.— Electrical **Measuring Instruments.** Part I. Commercial and Indicating Instruments 1924. 377 ills. 7 x 9½. Cloth. 440 pp. $12.50. VN.

Fowle, F. F.—. Standard **Handbook for** Electrical Engineers 5th ed. Thoroly revised. 2139 pp. Illd. Thumb-indexed. 4 x 7. Limp leather. $6.00. McG.

Gray, Alexander—. **Principles and Practice** of Electrical Engineering. 412 pp. 449 ills 7 x 10. Cloth. $3.00. McG.

Hazeltine, L. A.—. Electrical Engineering. 625 pp. Illd. 8vo. $6.50. 1924. M.

Karepetoff, V.—. **Experimental** Electrical Engineering. Vol I. 3d ed, revised. 827 pp. 391 ills. 6 x 9¼. Cloth $6.00. 1922. W. Vol II. Manual for Electrical **Testing** for Engineers and Students in Engineering Laboratories. 2d ed, corrected. 347 pp. 209 ills. 6 x 9¼. Cloth W.

Manson, A. J.—. **Railroad** Electrification and the Electric Locomotive. 332 pp. 148 ills. 6 x 9. $4.00. 1925. S-B.

Mears, J. W.—, and Neale, R. E.—. Electrical Engineering Practice. Vol. I. 4th ed, rewritten and enlarged. 595 pp. 5½ x 8½. 92 ills. Cloth. $6.00. 1924 W.

Pender, Harold—, editor in chief **Handbook** for Electrical Engineers. 2d ed, revised. 2270 pp. Illd. 4¼ x 7. Flexible. $6.00. 1922. W.

Pender, Harold—. **Principles** of Electrical Engineering. Revised. 438 pp. 138 ills. 6 x 9½. Cloth McG.

Sheldon, Samuel—, and Hausmann, E.—. Electric **Traction and Transmission** Engineering 2d ed, revised. 307 pp. 127 ills 5½ x 7¾. Cloth. $3.00. VN.

Sloane, T. O'Coner—. Standard Electrical **Dictionary.** New enlarged. 790 pp. 497 ills. 6000 definitions. $5.00. 1925. B.

Steinmetz, C P.—. **Theoretical Elements** of Electrical Engineering. 4th ed. 383 pp. 194 ills. 6¼ x 9½. Cloth. $3.00. McG.

Timbie, W. H.—. **Industrial** Electricity 713 pp 5¼ x 7½ 469 ills. 947 problems Cloth. 1924. $3.50. W

Timbie, W. H.— and Bush, Vannevar—. **Principles** of Electrical Engineering. 520 pp. 5¼ x 7⅞. 244 ills Cloth $4.00 1922. Answers to problems, 5 x 7¼. Paper. $0.25 W.

Woodruff, L. F— Principles of Electric **Power Transmission and Distribution.** 345 pp 6 x 9. 110 ills. Cloth $4.00 1925 W.

Electricity and Magnetism, 537.

621.4 Air, Gas and Other Motors.

Carpenter, R. C—, and Diedrichs, H.—. **Internal Combustion Engines.** Theory, Construction and Operation. 610 pp 379 ills. Tables. 6 x 9½ Cloth. VN.

Davey, Norman—. The **Gas Turbine.** 262 pp 100 ills. 6 x 9 Cloth. VN.

Daw, A. W.—, and Daw, Z. W— **Oil and Gas Engine** Power 1923. 232 ills. 81 tables. 7½ x 11¼. Cloth. 491 pp $12.00 VN.

Hiscox, G. D—. **Compressed Air.** 5th ed, revised. 665 pp 500 ills. Cloth, $5.00. Half mor, $6.50. McG

Marks, L. S.—, and McDewell, H. S— **Gas and Oil Engines** and Gas Producers. 360 pp 218 ills. 4¾ x 7¼. Leather $2.00. VN.

Marshall, W. J.— and Sankey, H. R.—. **Gas Engines.** 293 pp. 127 ills. 6 x 8½. Cloth. VN.

Peele, Robt.—. **Compressed Air Plant.** The Production, Transmission and Use of Compressed Air, with Special Reference to Mine Service. 4th ed, revised and enlarged. 531 pp. 254 ills 6 x 9. Cloth. $4.50 1920 W

Wells, G. J.— and Wallis-Tayler, A. J.—. The **Diesel Engine.** 6th ed. 1924. 139 ills. 5½ x 8¾. Cloth. 349 pp $5.00 VN.

621.6 Blowing and Pumping Engines.

Barr, W. M— **Pumping Machinery.** 6¼ x 9½. 483 pp. 287 ills. Cloth. $5.00. L.

Daugherty, R. L.—. **Centrifugal Pumps.** 202 pp. 111 ills. 6 x 9. Cloth. $2.00. McG.

deLaval, C., G—. **Centrifugal Pumping Machinery.** 184 pp. 170 ills. 6 x 9. Cloth. McG.

Fleming, B. P.—. Practical **Irrigation and Pumping.** 242 pp. 62 ills. and diagrams. 19 tables. 5¼ x 8. Cloth. $2.00. W

Ivens, E. M.—. **Pumping by Compressed Air.** 2d ed, revised and enlarged. 1920. 266 pp. 6 x 9. 124 ills. Cloth. $4.00. W.

Weisbach, Julius— and Herrmann, Gustav —. **Mechanics of Pumping** Machinery. 300 pp 197 ills. 6 x 9. Cloth. $4.00 Munn & Co., 361 Broadway, New York.

621.8 Transmission Mechanism.

Hess, H. D—. Machine Design; **Hoists, Derricks, Cranes.** 374 pp 318 ills. 18 plates. 6 x 9½. Cloth. L.

Hetzel, F. V.—. **Belt Conveyors and Belt Elevators.** 333 pp. 6 x 9. 291 ills. Cloth. $5.00. 1922. W.

Jones, F D.—. Mechanisms and **Mechanical Movements.** 320 pp. 6¼ x 9¼ Cloth. $2.50. VN.

Simmons Boardman Publishing Co. **Material Handling Cyclopedia.** 850 pp. 1500 ills. 9 x 12. Buckram. $10.00. Leather, $15.00. 1922. S-B

Zimmer, G. F—. The Mechanical **Handling of Material.** 3d ed Thoroly revised. 1922. Over 1100 ills. 7¼ x 10½. Cloth 824 pp. $15.00. VN.

Principles of Mechanism. See also 531, Mechanics: 621. Mechanical Engineering.

Electrical Transmission. See 621.3 Electrical Engineering.

622 Mining; Earth Handling.

622.2 Practical Mining.

Ketchum, M. S—. The Design of **Mine Structures.** 475 pp 265 ills. 65 tables. 6½ x 9. Cloth. McG.

Peele, Robt—. Mining Engineers' **Handbook.** 2375 pp. Illd 4 x 7. Flexible Fabrikoid. In one vol, $7.00; in two vols, $8.00. W.

Young, G. J—. **Elements** of Mining. 2d ed. 6 x 9. Cloth. $6.00 1923. McG.

Mine Surveying, see 526.9.

Compressed Air, see 621 4.

Explosives, see also 660.

Retaining Walls, etc., see 721.1.

622.21 Excavation.

Gillette, H. P.—. Handbook of Rock Excavation. **Methods and Cost.** 825 pp. 184 ills. 5¼ x 7½. Leather. $6.00. McG

Massey, G. B.—. **Engineering** of Excavation. 376 pp. 6 x 9. 196 ills. Cloth. $6.00. 1923. W.

McDaniel, A B—. Excavation **Machinery, Methods and Costs.** 1st ed. 530 pp. Illd. 6 x 9. $5.00. McG.

McDaniel, A. B—. Excavating **Machinery.** 339 pp 134 ills. 30 tables. 6¼ x 9¼. Cloth. $3.00. McG.

Prelini, Chas.—. **Earth and Rock** Excavations. 363 pp. 167 ills. 8vo. Cloth VN.

Earthwork, see also 625.1ae.

622.26 Tunneling.

Brunton, D. W—, Davis, J A.— and Davies, J. V— Modern Tunneling 2d ed. Revised and enlarged. 622 pp. 6 x 9. 119 ills. Cloth. $6.50. 1922. W.

Hewett, B. M. H.— and Johannesson, S.—. **Shield and Compressed Air** Tunneling. 465 pp. 170 ills. 6 x 9. $5.00. 1922. McG.

Lauchli, Eugene—. Tunneling. 238 pp. 197 ills. 6 x 9. Cloth. McG.

622.32 Hydraulic Mining.

VanWagenen, T. F.—. **Manual** of Hydraulic Mining. 18mo. Cloth. VN.

Wilson, E. B.—. Hydraulic and **Placer Mining.** 12mo. Cloth. W.

624 Bridges and Roofs. (Roofs, see also 624.9).

Burr, W. H.— and Falk, M. S.—. Graphic Method by **Influence Diagrams** for Bridge and Roof Computations. 286 pp. 162 ills. 8vo. Cloth. W.

INDEX.

The numbers refer to the **pages.**
In the alphabetical arrangement, **minor words,** as "and," "between," "in," "or," "through," etc, **are neglected.**

See also Table of Contents, pp xxii, etc.

A

Annuity—Axis.

Bubble-tube—Cart.

Cartridge—Cement.

Cement—Chlorine.

Coal—Column.

Concrete—Concrete.

Concrete—Conveyor.

Crowd—Cylinder.

Diagram—Dowels.

E

Equilateral—Ferrule.

F

Fiber—Force.

Friction—Giant.

G

Gill—Gravity.

Gravity—Hemisphere.

Hemlock—Hyperbolic.

I

Layout of plant—Lining of tunnels.

Link—Lower.

Money—Mortar.

Mortar—Nozzle.

Panel—Pile.

Pile—Pipe.

Pipe—Point.

Pile—Pipe.

Q

R

Radius—Railroad.

Rip-rap—Ropeway.

Station—Steel.

Stepped formula—Stress.

Timber—Train.

U

Water—Well.

THE END.
